In the year 1824 Mr. Phillips published his first translation of the Pharmacopœia Londinensis; and subsequently he was consulted by the College of Physicians respecting the chemical preparations of the Pharmacopœia of 1836. Of this work he soon afterwards published a translation, enriched with a vast mass of information contained in the remarks and notes he appended to each preparation.

For this task his rigid accuracy, both in experimenting and in composition, peculiarly fitted him; and the selection of him by the College of Physicians to conduct their investigations upon the various preparations contained in their publication, is the best evidence of the opinion of that learned body as to his merits as a pharmaceutical chemist.

Previously to the appearance of the recently-issued London Pharmacopœia he was again often consulted by the College; and upon a translation of this work (the London Pharmacopœia of 1850) he was engaged a few evenings before his death. This, we find, is already in the press, and may shortly be expected. To the collection and arrangement of information which the researches of the last ten years have afforded, and which is capable of being embodied in this translation, he has for years devoted himself, with the evident object of making perfect this, his final work. Alas! that it should be a posthumous one.

Mr. Phillips was a member of the Council of the Royal Society for some years before his death. He was one of the founders of the Geological Society; and held the presidency of the Chemical Society of London for the last two years. He was an honorary member of the Medico-Chirurgical, Pharmaceutical, and other scientific Societies. As a critic on chemical and pharmaceutical subjects his fame was widely known, and great practical good has resulted in many quarters from the truthful severity of his strictures. Beloved for his kindness of disposition and cheerful wit in private life, and distinguished for his scientific acquirements and modesty in his public career, he has closed an active and useful life amidst the lasting regrets of a

numerous circle of personal and scientific friends. His remains were interred at Norwood Cemetery.

Lately, at Kensington, Henry Smith, Esq., surgeon, late of Torrington Square.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

LANCASHIRE AND CHESHIRE BRANCH.

The Fifteenth Annual Meeting of this Branch will be held at the Town Hall, King Street, Manchester, on Wednesday the 25th June, inst. The chair will be taken at 12 o'clock precisely, by Thomas Turner, Esq., of Manchester, President for the year. Dinner will be provided at the Albion Hotel, (opposite the Royal Infirmary), at *three o'clock*, for those members or friends who signify to the Secretary, on or before the 23rd inst., their intention of being present.

JOHN HATTON, Secretary.

114, Oxford Street, Manchester.

BATH AND BRISTOL BRANCH.

The Bath and Bristol District Branch will hold its annual meeting on Thursday, June 26th, at half-past two o'clock, at the Bristol Medical Library, Orchard Street, Bristol, under the Presidency of J. A. Symonds, M.D. The dinner will take place at the Bath Hotel, Clifton, at six o'clock.

JOHN COLTHURST,
Hon. Sec., Bristol District.

SOUTH-EASTERN BRANCH.

The members of this Branch of the Association, comprehending those residing in the counties of Kent, Sussex, and Surrey, are respectfully informed that the members of the committees of management, including the Presidents of the present and the ensuing year (the anniversary being always held on the last Wednesday in June) have been consulted, and they agree in opinion that the meeting of the entire Association having been appointed to be held this year within the district, namely, at Brighton, the usual annual assemblage of the members of this branch appointed to be held at Folkestone, may with propriety be postponed until next year, when the arrangements made at the Guildford meeting will be carried into effect at Folkestone, on Wednesday, the 30th of June, 1852.

THOMAS MARTIN,
Secretary and Treasurer.

Reigate, June 2nd, 1851.

SUFFOLK BRANCH.

The Anniversary Meeting of the Suffolk Branch of the Association, will be holden at the Town Hall, Framlingham, on Friday, the 27th of June.

Members of the Council will meet at the residence of the President elect, Wm. Jeafferson, Esq., at one o'clock, and the Chair at the General Meeting will be taken at two o'clock, precisely.

The members and their friends will dine together at the Crown Hotel, at five o'clock.

Short papers, or briefly detailed cases of practical value will be desirable; members unable to attend are respectfully informed that any communication they may wish brought before the meeting will be taken care of by the Secretary.

It will facilitate arrangements, if members would be kind enough to intimate to the President-Elect, Mr. Jeafferson, or myself, whether it is their intention to be present at the Dinner or not.

CHARLES ROBERT BREE,
Hon. Sec.

Stowmarket, June 9th, 1851.

P.S.—Members who have not paid their Subscriptions, and who are not likely to attend the Meeting, are requested to send them to me, by post-office order.

It is desirable that subscriptions should be paid before the 30th of June.

THE NORTH WALES BRANCH.

The Annual Meeting of the North Wales Branch of the Provincial Medical and Surgical Association will be held at the Crown Inn, Denbigh, on Tuesday, the 17th day of June next. The chair will be taken at twelve o'clock, when the business of the meeting will immediately commence.

It is earnestly hoped that Members will attend the ensuing meeting, and contribute papers, cases, &c., for discussion; and it will facilitate the business of the day if due notice of such intentions be given to either Secretary.

As the Journal of the Association is open to receive any papers, and publish them in full, it is considered expedient that in the more extended communications a *vivâ voce* abstract only shall be received at the meeting.

Dinner on the table at four o'clock.

EDWARD WILLIAMS,
D. KENT JONES, } Hon Secs.

NOTICE TO MEMBERS.

The publishers having received information that there has been some irregularity in the transit of the *Journal* through the post, it is particularly requested that any gentleman not receiving it punctually will immediately communicate the same to the office of the Association. The *Journal* is published every alternate Tuesday, and despatched in time for the evening post or the Wednesday's day mail.

TO CORRESPONDENTS.

Communications have been received from Justicia, Birmingham Pathological Society, Dr. Tilt, Mr. Hardy, Amicus Veritatis.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

[Reported by MR. HENRY GREEN, Student.]

LECTURE VI.

On the Morbid Conditions of the Heart and Circulating Tubes.

Anæmia.—The condition of anæmia, or scantiness and tenuity of blood, has, as might be inferred, a considerable effect upon the central organ of the circulation. This condition may arise from direct hæmorrhage, from a course of starvation, from the exhausting discharges of leucorrhœa, dysentery, or albuminuria, or from the ordinary waste of the nutrient fluids, under the non-assimilation of such diseases as phthisis, diabetes, chlorosis, &c. The blood, under such circumstances, becomes more fibrinous, and less albuminous in its nature, and exhibits a very marked diminution of the red globules. The condition is indicated externally by the attenuated and pale appearance of some patients, and the puffiness and pale aspect of others. The cheeks, the canthus of the eye, and the tongue, and lips, and gums, will seem blanched. In the female the catamenia will be of a faint colour, or altogether absent. There will be an inclination to dropsical effusions, with general constitutional debility and loss of muscular power; and if the patient die, and the body be examined, its tissues will be found divested of their usual brilliant colour. The numerous causes stated above as indicative of this degeneration, are reducible ultimately to two distinct heads, viz., either a primary failure in the powers of assimilation, or a secondary drainage of the fluids after their elaboration. The first is represented under the general term of indigestion in its largest sense, as including, not only an imperfection of function in the stomach, &c., but also in the lungs; the second comprehends a vast category of complaints, yet all more or less partaking of the nature of atrophy. Thus, under non-assimilation, we must rank phthisis, diabetes, and all the multitudinous forms of visceral derangement comprehended in the name of simple dyspepsia; while, under atrophy, we must class together every more or less complete drainage of the nutritive fluids of the body, such as diarrhœa, albuminuria, or menorrhagia. But, from whatever of these different causes anæmia may spring, it is invariably found that the red particle is the chief ingredient of the blood that is wanting, and that fresh blood is most readily elaborated when that element is furnished to it. I speak of this anæmia, however, at present, only in connection with its special effects upon the heart. These are the inductions of habitually numerous, rapid, and weak contractions, with occasional palpitations, a faint, jerking pulse, and, sometimes, a gentle bellows sound accompanying the ventricular systole. As this sound is often heard without any appearance of altered structure in the heart, it has been common with the best authorities to rest contented with the assertion, that it is a necessary consequence of attenuation of the blood; this, however, I am much inclined to doubt, for were it invariably due to that cause alone, then in such cases the administration of a medicine that liquefied the blood further, would necessarily increase the vehemence of the murmur; whereas in certain instances of anæmic rheumatism, in which, as is usual with that disease, the pulse was not particularly quick, having reason to suspect that the murmur was owing to the fibrinous condition of the blood, whereby clots might accumulate about the valves of the heart, and so cause a physical, though not an organic obstruction, we administered nitrate of potassa alone, and certainly, from the period of its exhibition, there was a decided abatement of the blowing sound. The decision of this matter is of great consequence, as every hinderance of the free circulation of the blood must materially retard recovery from rheumatism; and it is satisfactory to know that in some instances such an event may be warded off by so simple a remedy. From the flaccidity of the heart under such circumstances of anæmia, the impulse must of consequence be weaker than usual, except hypertrophy exists along with it, which it sometimes does; and the pulse, for the same reason, will then be jerking, and tremulous, and easily compressible.

The treatment must necessarily be varied, according to the variety of causes and accompaniments of the disease. Thus, in phthisis, we must bend our attention to the lungs, in diabetes to the stomach, kidneys, and capillaries; in amenorrhœa, to the womb; in albuminuria to the kidneys, and so on, according to the seat and nature of the morbid action, or morbid discharge. But in every case, without exception, and most expecially in chlorosis, phthisis, and other pure degenerations, our chief reliance must be placed on iron, as one of the essential elements of the red globule, along with a supply of oil and phosphate of lime in those cases which are accompanied with emaciation. And here I shall take occasion to observe, that in common with Dr. Cullen, I prefer not merely the carbonate of iron, but the common rust, or old rubigo ferri, to any other preparation of that metal. More soluble and more perfectly pure salts of iron have certainly been devised by chemists; but I think we may fairly trust to such acids as are in the digestive canal to dissolve quite as much of the oxydated iron as the system can appropriate, and then the rest can do no harm, for it never causes griping, or sickness, as the muriate, &c., will sometimes do. As for perfect purity of the metal, I do not think it advantageous, inasmuch as the iron of the blood, like the iron of external nature, is always found in combination with a minute proportion of manganese, which it is therefore advisable should be supplied at the same time, though it cannot be done if the salts be over purified, as is now often the

boast of the modern chemist. Good nourishment, fresh air, and the usual accompaniment of the tonic regimen, must also be included. These cases of anæmia are so numerous in this town, and you have seen so very many, especially amongst females, that individual references are quite unnecessary.

Hyperæmia of the heart or its membranes may assume the forms of simple determination of blood, or congestion, or chronic or acute inflammation. Simple determination of blood is generally the result of certain extraordinary efforts made by the muscular tissues in order to overcome some unwonted obstacle or burden. In the heart such obstacle or burden is commonly connected with certain impediments to the circulation, either as regards obstructions offered to the forward motion of the blood or facilities for its unnatural regurgitation. To overcome the resistance, efforts are made, and these efforts naturally lead to a determination of blood and an increase of the muscular tissue. This increase may often exist to some extent, without giving rise to any particular uneasiness, except when other parts of the body are suffering from inflammation or congestion, in which case, the increased impulse of the heart will certainly aggravate the symptoms. This will more especially be the case when the hypertrophy is of the eccentric kind, or accompanied with dilatation, as, under these circumstances, there will not only be increased impulse, but an increased volume of blood pushed forward at each contraction. In the simple hypertrophy of the concentric kind, in which the cavities are reduced in size, but without any valvular obstruction, few symptoms will present themselves beyond some increased impulse of the heart, and a diminution of loudness in the sounds. There may be no extended dulness, and the only thing that the patient may complain of is dyspnœa, which may or may not be accompanied with cough. Such people are usually stout and broad chested. A good resonance will be elicited from the lungs, and they often entertain the impression that their shortness of breathing is merely due to fatness. They may be advised, or take upon themselves, to go through a great deal of hard exercise, with a view to reduce themselves, but soon find that the more they are exercised, the more the circulation is excited, and of course the efforts of the heart and the dyspnœa at the lungs is increased. In such cases it is certainly desirable to reduce the body, but that object must be effected by other means than hard work. With this view it is requisite that small quantities of blood should be drawn from the cardiac region at certain intervals, say every ten or fourteen days, while the system is placed under limited diet, along with sedatives. For such treatment to be successful, however, long perseverance is required. The abstractions of blood are found to relieve the dyspnœa very considerably, and the circulating fluids being calmed and diminished by the simple and restricted diet, the organ very gradually returns to a more natural proportion. At all events it will most probably be prevented from being augmented, and many secondary and tertiary evils will certainly be warded off for an indefinite period, such as would otherwise undoubtedly arise from the obstructions that must, if unremoved, be propagated backwards, first to the lungs and thence to the right side of the heart and general venous circulation. The mode of treatment, as you will observe, is simple enough, and the great difficulty chiefly lies in persuading the patient to persevere long enough with so self-denying a course of discipline. Such persons are not unusually of rather jovial habits, and although from the great and immediate relief afforded to their dyspnœa by the abstractions of blood, they will resort cheerfully to a few leeches whenever that symptom distresses them; yet I fear their neglect of the second rule is almost universal. Their own natural inclinations, seconded by the pressing hospitalities of inconsiderate friends, are likely enough, to overcome their allegiance to the physician, and so these cases, though often relieved, are very seldom perfectly cured. Not that the cure is a matter of any great difficulty, for we have numerous instances of it, and Dr. Hope thought it a very tractable complaint; but the discipline is seldom carried out.

Hypertrophy combined with dilatation, is a much more formidable disease, for the obvious reason that there is not merely a powerful contraction of the heart, but also a vast volume of blood pushed into circulation at each stroke. The symptoms of this malady will be considerably varied according to the side of the heart most involved, and the proportion that may happen to exist between the solid hypertrophy, and the dilatation. In all cases there will be an extended dulness under percussion, the motions and sounds of the heart will be more or less violent and irregular, and most probably there will be a distinct bulging of the ribs. If it affect the right ventricle, however, the impulse of the apex will be felt to the right of the sternum, and perhaps below it, while the dyspnœa, and the jugular pulses will be very apparent., (as in the case of Wragg.) If the parietal hypertrophy be proportionate in force to the weight of the ventricular blood, the action of the heart in correspondence with the pulse will be powerful, bounding, and vehement, raising the head of the listener on the stethoscope, as it were, and eliciting from the intercostal muscles, a grating vibration of their fibres. (As illustrated to you by many cases in this hospital, both of in-patients and of out-patients.) But if the walls be disproportionally thin, as compared with their cubic contents, then the action will be comparatively weak and prolonged, or divided into so many efforts, like the irregular intermittent pulse that attends the disease, as if the ventricle made a succession of contractions to effect that which it could not master at once, the final stroke being the only strong one. This condition was illustrated in the woman Wheeler, and in the man Bevan, whose cases I shall recal to your memory.

Mary Ann Wheeler was a good looking woman, in the second ward, aged about 40. She entered the hospital labouring under a great degree of dyspnœa and bronchitic asthma. The lower extremities were very œdematous, there were increased dulness and impulse at the cardiac region, and also a double systole

of the heart, irregularly performed. The sounds corresponded to these peculiar motions, but otherwise were natural enough in tone. The latter stroke was the heavier one, and the first seemed only the commencement of an effort in which the organ was compelled, from some cause or other to make a pause. Judging from the urine and the stools, &c., the liver and kidneys were quite healthy. She had no sense of pain, except under the left breast, nor any other uneasiness, except from the condition of the lungs. She was treated with regular successions of small abstractions of blood, blisters, and belladonna plasters, while she took lobelia and digitalis, in conjunction with other expectorants and diuretics. Under these courses, the cough, dyspnœa, and wheezings entirely disappeared, the anasarca also left, and the heart, though still giving the double first movement, when she left the house, had become mild and regular in its rhythm. After the diuretics and sedatives had done their work, she only had digitalis, in combination with muriate of iron, which renewed her colour, and gave her a considerable accession of strength.

James Bevan, aged 30, looked pretty well on admission, and something occurring to prevent the usual minute examination at the first appearance, he was merely treated for a cough, and some degree of neutral vomiting. At the next visit great dyspnœa was observed, along with intermittent pulse, and on turning our attention to the heart, very extensive dulness was discovered, as well as most irregular motions, as if the ventricle made three or four ineffectual efforts to expel its contents, and, at length, a very violent one. The sounds exactly resembled the boiling of some thick fluid in a cauldron, and over the heart there was a high degree of bulging of the ribs, while pain was complained of under the left scapula, towards the spine; a jogging action was, at the same time very apparent. The diagnosis formed was that there were adhesions, with hypertrophy and dilatation, but that the latter was in great predominance. The indications were to relieve the organ from its distending fluids, while firmness and steadiness of action should be given to the muscular walls by means of sedatives and tonics, combined. Accordingly he was moderately cupped at certain intervals, regulated by the increased action of the organ, while he applied in the interim, belladonna plasters, and took first digitalis, in combination with Fowler's solution, and afterwards the same sedative along with muriated iron. Quietude was at the same time strictly enjoined. After a course of this kind, pursued steadily for upwards of two months, he left the hospital quite free from any vehement or even irregular action, except an occasional intermission. Having gone to hard work, he returned ill in about six months again, but was again restored so as to be able to be engaged in our dispensary as light porter.

In the case of Bevan just cited, it will be perceived that the peculiar action of the ventricle above alluded to produced an equally peculiar sound, likened to the boiling of some thick liquid in a pot, but of course there will be every gradation of such symptoms, from one extreme of decided hypertrophy, with some dilatation, to the other extreme of decided dilatation, with some hypertrophy. This condition of hypertrophy may exist either with or without valvular obstructions. Where none are to be found, we shall have only the presence of a strong impulse, and perhaps this bubbling sound, or a slight murmur.

In the successfully treated case of Thomas Harrison, aged 22, a blacksmith, near Dudley, there were no murmurs. He had been placed in early life to hard work, and had about twelve months before began to feel shortness of breath, and afterwards violent palpitations. He was pale, thin, and subject to throbbing headaches. There was a large bulging over the left side, with violent action of the heart, while the pulse habitually beat 120, and the respirations were 32. For about three months he underwent a steady course of local leechings, blisterings, and applications of belladonna, while the bowels were kept open, and he took digitalis and iron. Perfect quietude of mind and body was also enforced, and at the end of that period his flesh and complexion were much improved; he had no headaches, the bulging almost disappeared, and the violent cardiac commotion and dyspnœa had so far disappeared that the pulses were 72, steady and soft, while the respirations did not exceed 20. He felt, in fact, perfectly well. He was a young man of intelligence, and well capable of self-government; accordingly, he refrained from all stimulants throughout, and persevered with the digitalis, notwithstanding its frequently depressing effects, which he ultimately avoided by taking the doses at six instead of three times a day. He also ultimately changed his laborious business for that of a dealer in butcher's meat; and his case affords us a very excellent illustration of the comparative ease with which we can overcome cardiac hypertrophy, if it be uncomplicated with valvular disease.

But when valvular imperfections are present under such circumstances, the sounds that attend them will be increased in loudness or roughness, according to the degree of hypertrophy and dilatation. We may thus have the single or double murmur very loud, as they were heard in the cases of Shaw, Sarah Billings, and the large blacksmith Foxhall, of the detached wards, who all laboured under oppressive dyspnœa, and the first and last under inveterate dropsy. Or we may have a highly distinct musical murmur, either double or single. In Sarah Billings we sometimes had croakings like a frog, and at other times cooings, either double or single. The former will indicate the presence of something that is rough, and inelastic, such as the calcareous cauliflower excrescences of Shaw, Twells, and this Billings, &c., while the latter will be associated with some other kind of growth that is tough, tense, and elastic, vibrating under the current of blood, and producing a chirping, a cooing, a shrill croaking, or even a loud and sharp moaning sound, precisely resembling the human voice. These were specially illustrated by Billings's case. More or less dyspnœa must necessarily exist in such cases, along with a tendency to headache, hæmorrhage, and inflammation.

Unless there be valvular obstruction or regurgitation, however, there may be no inclination to dropsical effusions until the lungs are so far affected as to be habitually gorged with blood—a fact which will be found illustrated in several of the cases here adduced, as well as in daily practice. Thus, most of the cases of the out-patients, even though some of them were accompanied with a degree of mitral obstruction and regurgitation, were free from the dropsical symptoms, which, if they had supervened, would soon have driven them within the walls of the hospital, whereas mere dyspnœa excites but little alarm.

In illustration of which observation I shall briefly recount the circumstances of the case of John Anderson, in the side ward at the top. He was a large young man and respectable machinist of 30, who had lived rather a free life. He had had very slight attacks of rheumatism, but had not sought hospital advice till the advent of his dropsical symptoms. On admission his legs were much swollen, he had great dyspnœa, and though he had no visible bulging over the heart, from the naturally large capacity of his chest, yet he complained of settled pain in the left side, where the heart beat powerfully and rapidly 120 in the minute, each beat being accompanied with a loud double murmur. Hypertrophy and dilatation, with obstruction and regurgitation, were diagnosticated, along with inflammatory action. He was frequently cupped and blistered, and also once bled in the arm, with temporary relief of the pain and the dyspnœa, but no more. Diuretics would not act, even though he was previously leeched over the kidneys. Neither could drastic purgatives keep down the dropsical effusions, which at length became so universally oppressive that he had no strength to bear their action. Thus, with hydrocele, ascites, hydro-thorax, general anarsarca, engorgement of the lungs, a heart labouring violently at 160, and respirations at 40, he terminated his painful illness. After death, the amount of effused serum was found to be immense; the kidneys were partially degenerated; the lungs were almost solidified with the old engorgements. On the left side was extensive pleurisy; but, most especially, the heart was found to weigh one pound and a half, all its cavities being much distended, while the wall of the left ventricle was about an inch and a quarter thick. The valvular disease consisted of a large opening of three quarters of an inch in diameter in one of the aortic valves, the remainder of which looked like a ring, the centre having been destroyed by ulceration. Behind this ring was also seen a pouch in the aorta, covered with a thick rough white membrane, and dotted or partially-crusted with phosphatic deposits.

— Foxhall, the blacksmith, was in much the same state as Anderson, though the symptoms were not so very urgent. He had been placed in early life to hard work, and had also continued to labour in his maturer years with a very heavy hammer. No doubt he had drunk a good deal to sustain himself under these exertions. The result seemed to be the induction of valvular disease, with obstruction and regurgitation at most of the apertures, followed by hypertrophy and dilatation. The action of the heart was bounding and violent, the double murmurs were very loud, the wrist pulse was intermittent, the jugular pulsations were distinct, and there was extensive dulness. The anasarca and ascites were far advanced, and there were engorgement and sluggishness of action in the liver, kidneys, and bowels. There was dyspnœa, with a dusky complexion, yet not to such a degree as to prostrate him. Neither purgatives, diuretics, nor sudorifics seemed to diminish the amount of effusion, for indeed they could not act; and the cuppings over the heart only relieved any increase of dyspnœa that occasionaly occurred. Incisions were made with the view of facilitating a reduction of the legs; but threatenings of erysipelas made us abandon such a course. He left the hospital as he entered it, and I have not heard of him since; but undoubtedly the final result of his case must ultimately be, or have been, the same as that of Anderson.

The treatment must, of necessity, be varied according to the different symptoms already enumerated, and the conclusions at which we may arrive as to the proportion which the hypertrophy bears to the dilatation. But the great objects must be to abate the violence, to increase the steady vigour of the heart's motions, and to lessen the amount and force of the circulation. With this view, where hypertrophy is found to be considerable, strict rest, with low diet, and sedatives, is to be enjoined, while blood is locally abstracted at intervals, and the bowels kept in an open state. Where dilatation predominates, rest and sedatives, and abstractions of blood, will be equally necessary, as the latter measure tends to lessen the amount of the dilating fluid, and gives free play to the lungs; but it will generally be advisable to conjoin tonics with the other medicines, such as arsenic, quinine, or iron, and indeed the latter may often be necessary in simple hypertrophy itself, if the patient be very languid or pale, for, although simple hypertrophy and dilatation may often be accompanied with a broad, muscular, and vigorous frame, yet I have never found it coupled with valvular disease, without the patient being pale, faint, and thin. Some may appear plump from obscure anasarca, but on discharge of the fluid the leanness is apparent. Even under the most favourable circumstances the treatment must necessarily be very tedious. Blood in small quantity, either by leeching or cupping over the heart should be abstracted every ten or fourteen days, according to the vehemence of the pulsations, or the distress of the dyspnœa. The patient should be kept in perfect tranquillity of body and mind. The diet should be mild and unstimulating, and moderated or augmented according as the hypertrophy or dilatation may exceed one another. The circulation should be further lowered by the administration of such sedatives as digitalis and hydrocyanic acid, along with tonics, as already mentioned, if dilatation and general debility be in excess. After as much blood has been drawn as may seem judicious, a blister may be laid on over the heart, and after that a belladonna plaster. During the whole period the bowels and kidneys must be kept in

free play, if no local disease forbids their being irritated; and they must further be stimulated to purgation and diuresis, in the event of any of those secondary complications arising, which are apt to supervene, such as hyperæmia of the head or lungs, or dropsical effusions. The very successful issue of treatment of this kind is to be witnessed in the case of Thomas Harrison, already cited.

When the valves are much altered in structure, this treatment can only be expected to ward off imminent symptoms as they arise, prolonging life for an indefinite period, so long as quietude is maintained, but seldom tending to bring about any fitness for active exertion. When, however, the valves are not, or only slightly, involved, we may entertain considerable hope of being able to reverse the morbid action, and bring the organ to a state of health. This can only be done, however, by the assiduous assistance of the patient himself, who will generally be very docile, while yet the inconveniences of his malady hang about him, but who naturally becomes impatient of the discipline of treatment so soon as his most urgent symptoms are subdued. Hence we see so many reliefs and recurrences of the disease before it proves fatal. Workmen will go to their work before they should; merchants will pine with impatience to be back to the interests and cares of their offices; country gentlemen disdain to sit still at home, or loll in their carriages, while their companions are galloping over hill and dale, or climbing the mountain steep, and all, in each relation of life, will fret at being kept from their favourite and habitual avocation without some very apparent cause. Thus these diseases will be often found to have run a long course before much notice has been taken of them. When brought under the observation of the physician they will also be frequently withdrawn after the most distressing feelings are alleviated, he feeling a natural delicacy, except in his public patients, to urge a continued line of treatment against the secret convictions of the sufferer himself. He must state the plain fact, if asked the question, (but he cannot be expected to plead for his own services when the patient may seem averse to them.) The fact of the symptoms not at first exciting much attention, has long ago been remarked to apply chiefly to the laborious classes. The strong throbbings and difficulty of breathing advance so gradually that the attention is not suddenly drawn to them until some other ailment or secondary affection so augment them that they can no longer be disguised; you will also frequently obtain very vague and indefinite information, from such persons. Thus, John Anderson, the Scotchman, whose case shows to you obstructions and regurgitations, great hypertrophy, oppressive dyspnœa, diseased kidneys, and universal dropsy, gave no particular account of any advancing illness beyond a little difficulty of breathing, with slight rheumatic pains, and never sought any regular medical advice till the dropsy frightened him, and yet all the while he was a doomed man, whose disease must have been of very long standing. Thus, also, the woman Billings, while suffering from habitual giddiness, headache, and dyspnœa, accompanied with a double moan over the aortic valve, said, in reply to the injunction concerning perfect rest and quietude, that she had, indeed, almost nothing to do, as she had only her husband to attend to. Yet, in answer to pointed and specific questions, she stated that she washed and ironed clothes, carried pails of water up stairs, made beds, scrubbed floors, and was in the habit of going to market in Dale End, in the centre of Birmingham, and frequently carrying thence weights, amounting to twelve or sixteen pounds, to her own home, two miles away. This was labour out of all bounds to one in her condition, yet she called it light as compared with the labours of other women, and so it was, except that the effects of it upon her were very distressing, while it would have only been a healthful recreation to others. This shows the necessity of always ascertaining precise and positive facts, and not trusting to the mere impressions of others. Different people have very different ideas as to relaxations or constipations of the bowels, or heat, or cold, or quickness or slowness of breathing, &c., &c., but you will never be deceived if you bring them to state these things, or ascertain them for yourself, in their number, magnitude, and weight, &c., which alone can guide you, or afford any safe basis of practice. It is the most unsatisfactory thing possible to read certain pretended reports of medical cases wherein such matters are expressed in that vague and inaccurate language which proves that the writers have no aptitude for observation themselves, nor expect any such aptitude in others; you will carefully avoid all such slovenliness. What you do report, report concisely, but leave out nothing that is essential to a true knowledge of the case. These observations comprehend, I think, the principal and simpler features of hypertrophy and dilatation of the heart, and the various cases already cited, will afford, on being read from the hospital books, practical illustrations of the minuter symptoms, and particular details of treatmeut. Some have expressed opinions as if sedatives and tonics were incompatible and contradictory; but these opinions appear to me neither sound in theory nor true in practice. There is nothing contradictory in soothing the irritability by one agent, while you impart vigour by another; and you must have again and again observed, that while by means of digitalis alone, we not only reduce the number of pulsations, but diminish their force, we shall by the combination of a tonic increase their force, and reduce their number at the same time. The establishment of such facts is of great practical importance in a number of cases, and you see me day by day employ a combination of digitalis and iron, &c., with the best effect, in numerous cases, besides those merely cited for illustration. Indeed, the digitalis of itself, will so prostrate the energies and reduce the appetite, &c., that the patient is very likely to omit its use; whereas, if without such unpleasant drawbacks, we can, as we constantly show you, still the vehement action, and bring down the bounding pulses from 120 to 60 or 70, of a moderate character, we effect all we want.

As to simple atrophy of the heart, it can occur, I should say, very seldom as an idiopathic disease. I allude here to simple atrophy or pure wasting, and exclude at present from consideration those other forms of atrophy, which are due to replacement of tissue, such as fat for muscular fibre, &c., and which shall be ranked under the head of degeneration. The laws of nature have in general so guarded such vital organs as the heart, that they are the last to suffer from mere loss of nutrition, as in this case of simple atrophy. The only local causes that could induce such a state are the presence of tumours, or other forces pressing against the organ, and so cramping its motions and promoting its absorption; or, on the other hand, an ossification of the coronary arteries, whereby the natural supplies of blood are stopped, and the tissues consequently diminish. In general, however, this cardiac atrophy is only an ultimate result from some long-standing and exhausting disease, such as interferes with the whole constitutional nutrition, or drains off the supplies to other morbid channels. Such are typhus fever, phthisis, diabetes, albuminuria, and cancer, in all of which maladies the heart is usually discovered to be very small, pale, and flaccid, provided there was no opposite condition of it before. In most of these cases (too numerous to mention) the pulsations will be very rapid, say to the amount of 140 or 160, as in phthisis, typhus, and cancer, in others it may not be above 100 or even less, up to the period of death, as illustrated in a remarkable manner by the cases of Eliza Sleuth, and Sarah Binion, the former sinking under the extreme of tubercular degeneration, and the latter under a very violent form of uterine carcinoma, and yet their pulses seldom being above 92 or 96, and generally only 80.

This seems to depend on the degree of general irritability, and also on the condition of the lungs, bowels, and brain—more than on any discoverable peculiarity in the organ itself. Several instances of this variability of the pulse, will be found in the cases above alluded to, especially in the phthisical ones, where the rise or fall seems to depend on the firming or softening of the tubercle. As to treatment—setting aside its connection with the other affections already named—that must consist simply in increasing the nutritive powers. The patient will be generally observed to be small, shrivelled, and blighted, as it were, in his natural growth, inasmuch as the atrophy is very often congenital; but if it be an induced affection in after life, the body will have become lean, the pulses will be faint and languid, and the surface and extremeties will be inclined to cold. In either case, stomachic bitters, such as calumba and biberine, should be given to promote the appetite. When that is excited, it ought to be satisfied with light nutritious food. A fair amount of open air exercise should be enjoined, and he should, further, take muscular tonics, such as quinine, and the carbonate or muriate of iron, but more especially the latter. Under such management, the accidental form of atrophy may be arrested, and the patient restored to pristine vigour; but the congenital kind will usually defy every effort, as we cannot restore that which never existed. These constitute the puny and withered little men and women that appear like magnified embryos during their whole lives, and who only continue to exist at all by the nursing care of a civilized society.

ON THE

MANAGEMENT OF WOMEN AT, AND AFTER THE CESSATION OF, MENSTRUATION.

By E. J. TILT, M.D.,

Senior-Physician to the Paddington Free Dispensary for Diseases of Women and Children, and Physician to the Farringdon General Dispensary and Lying-in Charity.

As the track of the peasant in crossing a field is never a straight line, but is made up of a succession of undulations, so the pilgrim in his journey over the plains of scientific research seems to be constantly describing zigzags between extremes. The history of blood-letting well illustrates this oscillating tendency of the human mind. The profession has sometimes used this most valuable of remedial measures to a disastrous extent, while at others they have neglected it altogether; this partly depending no doubt on a variation in the epidemic medical constitution, but still more on the remembrance of the previous excesses, or on the influence of fashion. If Dr. Holland were to rewrite his "Medical Notes and Reflections," he would no longer say as he did years ago, that "current opinions and prejudices are wholly on the side of bleeding," and "that a physician needs all his firmness to decline the practice." Now, on the contrary, the tables are turned, and those who, in their dogmatic writings, advocate the utility of bleeding in certain well chosen cases, conforming in practice to popular prejudice, never bleed; and would, I doubt not, add their testimony to that of a distinguished member of the profession, who told me lately that in the space of four years' attendance in private and hospital practice, he had only bled one patient.

Is it not probable that by totally neglecting blood-letting in inflammatory affections, we deprive ourselves of the means of making calomel, antimony, and other remedies exert their influence so speedy as they would, if their employment were prefaced by bleeding? Without stopping to discuss the subject, bleeding must undoubtedly be considered valuable in active hæmorrhage, and must exert its influence by its mechanical or hydraulic as well as by its dynamic effects, and it seems to me that the careful perusal of my last paper warrants the conclusion that the redundancy of blood which nature has no means of disposing of at the demise of the ovarian function, is the principal source of the disease of cessation, whence the following corollary, that blood-letting, so often effected by nature in these diseases, should not be overlooked by those who pride themselves on understanding and on imitating her proceedings.

Bleeding is in some cases the best mode of relieving

the inflammatory affections, the general plethora, the flushes, the perspirations, and the persistent headaches, by which women are so tormented at this time, but great discrimination is of course required, for of two patients suffering in an equal degree from the same symptoms, one will be injured and another benefitted by bleeding as in the following instances :—

Case.—In 1844 the rage for bleeding, developed and fostered by the passionate eloquence of Broussais, had subsided in Paris, but it was still often possible to test the ill effects of this pernicious system. About that time I was consulted by a lady, aged 51, tall, thin, with a pallid complexion, dark hair and eyes. She had first menstruated at 15, and the function had never been interrupted except by three pregnancies, the amount of secretion was moderate and the discharge subsided gradually, being performed for the last time at the age of 48. For some months she felt no inconvenience, but afterwards was much troubled by flushes and perspirations. She consulted an eminent French physician, who ordered her to be bled to ten ounces. A slight improvement followed, but the same symptoms soon returned, which were again interpreted as signs of plethora, and another ten ounces were withdrawn from the arm. This second bleeding did not in the least relieve the patient, and when I saw her the marked ill effects of the treatment made me think it might have possibly been injudicious. I found the pulse at 75, but as it not unfrequently becomes raised with advancing age, that rate alone could not warrant bleeding; besides, it was neither hard nor full. Not being able to explain the pains in the head, the flushes, and perspirations by plethora, I thought the nervous constitution of the patient might in some measure account for them, and I gave anodynes and mild purgatives, and advised a more strengthening diet. The patient rapidly improved, and in future relapses derived benefit from the same plan of treatment.

Case.—I was lately consulted by a lady aged 53, of middling stature, sanguine complexion, brown hair, and hazel eyes. She menstruated abundantly for the first time in her 13th year, and the function has since been pretty regularly performed, the discharge being usually abundant. While the function was ceasing she was twice seized with flooding, and felt better in health afterwards. Menstruation ceased at 51, and was soon followed by diarrhœa, which came on at irregular intervals, but did not interfere with the appetite and strength of the patient. When that supplementary discharge subsided, heaviness of the head, with giddiness, came on, together with flushes of heat and drenching perspirations. For these distressing symptoms she had consulted several medical men, and had taken large doses of quinine, acetate of lead, and gallic acid, but without benefit. I ordered her to be bled to twelve ounces. The vertigo, flushes, and perspirations abated considerably. I next recommended that the bowels should be kept open by Seidlitz powders; several glasses of effervescing lemonade to be taken in the course of the day, and a tepid bath for an hour every week. Meat once a day, no beer or porter, and one glass of sherry at dinner, and more exercise to be taken in the open air.

In a month all the painful symptoms had completely disappeared, and the patient remained well for several subsequent months, when, without any apparent cause, the same symptoms broke out again, as with a sudden burst. I ordered eight ounces of blood to be withdrawn, and prescribed the former treatment, with similar good effect; and I should do so again (diminishing as much as possible the quantity of blood to be withdrawn) whenever a neglect of the prescribed diet, or some unforseen nervous excitement, should bring on a relapse.

The symptoms experienced by both these patients were similar, but their constitutions were very different. In the last case the patient was of a strong constitution, accustomed to lose considerable quantities of blood, and was relieved by the occurrence. The rigour of her constitution was well proved by the strong impulse of both heart and pulse, replacing the weak and flaccid condition of those of the first patient. The one was relieved by sedatives and a strengthening diet, the other principally by bleeding; and I may add, that I have seen bleeding remove these symptoms when it was not indicated by a strong constitution, but by the previously-contracted habit of losing a considerable quantity of blood; as, for instance, in women of a slender make and slight delicate appearance, and in those whose nervous susceptibility is great, and in whom, as I have previously shown, we must admit a hæmorrhagic diathesis.

If the utility of venesection is proved in cases similar to the one last related, in which, in these days, its employment would be scarcely thought of, it stands to reason that the same means, combined with other remedial measures, should be resorted to when the temporary plethora produced by the change of life has given rise to inflammatory affections of the womb, or other organs.

At first sufficient blood should be taken away to make a decided impression on the system. The effects of the bleeding should be aided by the regimen recommended in my last paper, for doubtless the necessity for bleeding even plethoric women, would be considerably diminished if it were not so difficult to persuade them to break through accustomed habits, and if they would consent for a time to diminish the quantity of their food and reform from what we have shown to be otherwise prejudicial to them. The effect of a first bleeding may also be maintained by the remedial measures already mentioned or to be hereafter described, but it may become necessary about the second or third month again to take a little blood from the patient, and in some rare cases it may even be a third time advisable to resort to it, but a still smaller quantity should be withdrawn.

There is nothing new in this plan: it was that of our medical ancestors. It was that of Tissot, who seems to have paid great attention to the subject. It was followed

by Hufeland, and still commended by him at the close of his patriarchal career, and it is still advocated by Meissner to whom we must accord the credit of improving the state of medical practice in Germany. A plan sanctioned by such great names commends itself; also by the facility of understanding that the well-timed subtraction of a small quantity of blood from the veins of women accustomed for more than thirty years to lose periodically some of the same fluid, is the best means of preventing or curing diseases originating in the cessation of menstruation, until the constitution has lost the habit of making so much blood or acquired some safe means of disposing of it.

Having shown the utility of bleeding, I now proceed to discuss briefly the different modes in which blood may be taken from a patient.

The effects of venesection are:—

1. To diminish the mass and plasticity of the blood, and thereby the amount of caloric produced by the processes of nutrition.

2. To slacken the energy with which it flows to some particular organ—its momentum.

3. To diminish the congestion of some particular organ.

4. To diminish the intensity of the vital powers.

The effects of leeches are similar to those of general blood-letting, but while they subtract from the system the best blood contained in the capillary system, they cannot give that shock to the system produced by its sudden withdrawal of blood from its vessels. Local blood-letting, or the application of leeches to the womb, or to the labia, or even to the anus, are modes of relieving the congestion of the ovario-uterine organs which first suggest themselves, and these applications are often highly valuable in some of the forms of menstrual suppression, but to have recourse to them to relieve the symptoms depending on the cessation of the function, would in general be injudicious, for their employment would tend to maintain a discharge, for which the term has been fixed by nature. It can only be in some very rare cases that the application of leeches to the womb at that time can be sanctioned, as in the following instance communicated to me by a medical friend:—

Case—The lady's maid of a patient of his, 45 years of age, complained of violent pain in the loins, for which Dr. Bennet ordered a mustard poultice, but as it persisted, he recommended a blister to the lumbar region. This application was immediately followed by paraplegia, and a neighbouring practitioner, who was immediately sent for, did not hesitate to give it as his opinion, that the application of the plaster in a case of lumbago was an extraordinary proceeding, which he would never have thought of adopting; and although this assertion was contradicted by another medical man, who had been subsequently called in on account of the persistence of the paraplegia, my friend received several letters from the solicitor of the family menacing him with an action, but as he set them at defiance he heard nothing more of this attempt to make him pay for an occurrence impossible to foresee. The patient went home to her friends, and a country practitioner, more clear sighted in this instance than the eminent men of London, putting together the circumstance of the patient's age and the irregularity of menstruation, applied leeches to the womb. The result was a gradual diminution of the paraplegia, and now the patient is able to walk with perfect ease. Thus the local application of leeches may be useful to cure a disease of cessation, but in general when it is necessary to draw blood, it should be from the arm.

Older practitioners assert that the effects are very different if drawn from the arm or from the saphenous vein; at present, however, we look upon such distinctions as hair-drawn. It was formerly the custom to draw blood from the vena saphena, in cases of suppressed menstruation, requiring venesection; but during pregnancy a practitioner, fearful of producing abortion by following the same course, used to bleed in the arm. When suppression of menstruation takes place in plethoric women, I have often seen the menstrual flow return most favourably after bleeding in the arm; and thus far I think the dogmatists of a former period have overstated their position, but I would rather be guided by their opinion in the treatment of those terrible cases of suppression, determining symptoms of cerebral congestion of the greatest intensity, and often speedily followed by death. Instead of bleeding in the arm, I would apply leeches to the labia, and bleed in one or both legs, in addition to other treatment. I mention this incidentally, reserving for another time the facts on which I would ground the practice. At present I treat of diseases of cessation; and with regard to the employment of venesection, there is no disagreement amongst those who sanction the practice. All recommend the blood to be taken from the arm, thinking that by so doing they not only diminish the quantity and plasticity of the fluid, but even diminish the tendency to congestion of the abdominal organs. Blood-letting has detained us too long to admit of our now discussing the other modes of treatment applicable to diseases originating in the cessation of menstruation.

CASE OF

POISONING BY OXALIC ACID.

By J. DEANE, Esq., Chatteris.

Poisoning by oxalic acid is rare. The pain produced by it is too instantaneous, and too severe, to make it the resort of the suicide; and these very reasons, together with the rapidity of its fatal results, conspire to make it ineligible for the stealthy wickedness of the manslayer. The cases met with are, for the most part, accidental.

There is considerable discrepancy among toxicologists in their description of the symptoms of this form of

poisoning. The sensation at the throat at the instant of swallowing is differently described, according, probably, to the different experience of different writers; and the amount of neurotic symptoms has been a subject of discussion. Many of these cases being fatal, they cannot be correctly reported, as in the urgency with which we are obliged to act, and amidst the exhaustion and pain of the sufferer, a description of his sensations, or of the *subjective* symptoms is impracticable; the *objective* symptoms alone being appreciable by the medical attendant. My patient's recovery has, however, given me an opportunity of comparing my notes with his own statement, and I believe the following to be a faithful description of his case:—

J. P., 22, nervous temperament, slender and delicate, habits steady; occupation, draper's assistant. On the morning of the 11th of March (Thursday), having expressed himself as not feeling very well, he was recommended to take a dose of Epsom salts, and, by mistake, an ounce of oxalic acid, duly mixed in a cupful of water, was handed to him instead of the salts. Not liking to take medicine in the presence of his friends, he took it away with him into the warehouse; he was, therefore, alone when he took it. It was about eight A.M. He drank as rapidly as medicine is usually swallowed, but from a peculiar sensation instantly felt at the throat, he desisted, after having swallowed about three-fourths of the poison. He "felt as though his breath was going," he "was almost strangled," and he "had a horrible feeling of burning at the throat and stomach." He wondered what he had taken; was sure it was not salts, but had no idea of poison. He then attended to two different customers, and thinks five minutes must have elapsed before he gave the alarm. His appearance and his sufferings proved there was something wrong, and a brief inquiry among his friends elicited the cause. I was soon with him. He was suffering from prostration of all the vital powers; his countenance was pale and haggard, upper lip trembling, lower jaw relaxed; he had cold perspirations, especially about the forehead, and the extremities were cold; pulse small, irritable, and at once frequent and intermitting. He looked stupid, and I have since ascertained that he had at this stage of his case very little consciousness. He was taciturn; he held his hands without pressure, and with a look of agony, to the pit of the stomach; the slightest pressure on the epigastrium occasioned pain; his tongue and throat were redder than usual; there was profuse catharsis; his fingers now became contracted, and the finger nails dark; the countenance gradually assumed a darker tinge, and respiration became very quick and laborious. I have since learnt that he had a strange sensation of numbness about his limbs. Here were distinct symptoms of poisoning, which, together with the information given by the attendants, admitted no doubt of the action of oxalic acid. A table-spoonful of mustard in water had been given before my arrival, but it had not produced vomiting. I gave immediately about four ounces of prepared chalk in water, and hurried it into the stomach with the aid of the stomach pump. I found the mere presence of the tube sufficient to excite the muscular action of the stomach. I pumped two large basins of chalk and water into the stomach, and found no difficulty in securing its return. Constant vomiting being now kept up, and the fluids ejected as rapidly as they were introduced, I exhibited the antidote so freely, that all the remaining acid must have been neutralized, and I washed the stomach so thoroughly with chalk and water, that the resulting salt must have been removed. About fifteen minutes were spent in these proceedings. He was then arranged as for bed, but for convenience sake, we placed him in a reclining posture on a sofa, and, fully aware of his danger, we anxiously waited the result of the contest which his system would have to undergo. He continued to be sick. I found, however, to my satisfaction, that the fluids ejected were free from oxalic acid. Knowing, however, the necessity of works of supererogation in these cases, provided they do not distress the patient, I prevailed on him to take a basin of thickened milk, considering that if any oxalic acid crystals happened to be in the stomach, they would be taken up by a substance so pultaceous, and viscid, and that they would thus be removed, because I knew that whatever was swallowed would soon be ejected. He was now rallying rapidly. I had found it necessary to administer stimulants in small quantities. About two hours passed in this way. At half-past ten the matters vomited were tinged with blood, and very soon they consisted, to all appearance, of pure blood, of a bright arterial colour, and fluid. At one P.M. it began to take, and gradually took, the form of coagulation, and ceased towards night. During the entire day he had frequent attacks of cramp in the legs and feet, which were soon relieved by pressure. At eight P.M. I found him still vomiting whatever was given, but there was no trace of blood. During all this time he was allowed warm drink freely, as it made his vomiting easy. His pulse was more or less intermitting during the entire day; at this particular visit, eight P.M., it was 125, small, irritable, and intermitting. The skin was hot, his head ached, he complained of great exhaustion, and of severe pain at the epigastrium, increased on the slightest pressure. His tongue and throat were much paler, had a dingy whiteness about them, were very hot and dry to the touch. Thirst very urgent. A large blister was applied to the epigastrium. The state of the pulse prohibited bleeding, even by leeches. The next morning (nine A.M.) I found his symptoms much milder; pain relieved; febrile heat less; pulse 100, small, irritable, but not intermittent. He had had frequent startings during sleep, and much cramp in the limbs; frequently his hands were involuntarily clenched when awake. His finger-nails were dark, and remained so for several days. During this day (Friday) vomiting was frequent; in general it was free from blood, slightly streaked at times.

Catharsis having been one of the most distressing symptoms on Thursday, I did not require to administer a laxative. During the night of Thursday a peculiar eruption presented itself over the whole surface of the skin; it was an exanthema, and the dermatologist

would call it roseola. As it subsided it left the skin very dark, so much so as to attract the notice of his visitors. The cuticle afterwards desquamated.

Whether the exanthema was the result of some condition of the blood, produced by oxalic acid, or whether it was occasioned by gastric irritation; whether the dark appearanee of the skin was the declining stage of the exanthema, or the outward manifestation of some temporary change in the condition of the blood, or in any way a result of the semi-convulsive state of the system, I shall leave the reader to decide. Its disappearance by desquamation seems to make it merely a natural sequel of the eruption. I am not aware that these cutaneous symptoms have been before noticed in these cases.

The night of Friday the 15th was favourable, vomiting having occurred at slight intervals only, and without blood. I found him on Saturday morning in every way improved. There was but little febrile heat; pulse 94, fuller, and less irritable; no epigastric pain; headache very slight. There was a slight streak of blood in the matters vomited, and at four P.M. some vivid arterial blood, a symptom which gave some little alarm. Two hours afterwards he vomited a quantity of viscid secretion, and about a table-spoonful of dark coagulated blood, after which he expressed himself as much relieved. Sunday was yet more favourable, and from this time he gradually recovered his usual health and strength. He complained for several days of heat in the throat, and he suffered very much from thirst. He required laxatives for some days.

I am inclined to think that the last ejection from the stomach, which I have just described, was occasioned by the detachment of a slough of mucous membrane; but I could not satisfy myself on this point, although I carefully examined both the matters vomited and the alvine evacuations. The mucous coat must have been severely injured. Certain it is that from this time the vomiting distinctly abated; and the next morning (Sunday) I felt pretty certain of his recovery.

I shall not enter into any statement bearing on the treatment of the case. I have drawn up this paper chiefly as a description of symptoms. Death from oxalic acid is in general so rapid that we seldom have a clear and full view of the symptoms of a case from its first morbid symptom through the horrible stage of its violent action on the system and on the stomach, onwards to complete recovery. The case shows, in a remarkable manner, the action of oxalic acid on the nervous system, as well as on the mucous membranes. It points out very clearly the instant burning in the throat and stomach produced by it; and seems to prove, by the feeling of suffocation as instantly produced, that the neurotic symptoms are not occasioned by the injury to the stomach, but simply a direct action on the brain and nervous system, produced after a very rapid absorbtion of the poison. No medical man could have seen the first symptoms in this case without coming to the conclusion, that the deaths, almost instantaneous, of which we hear as resulting from oxalic acid are due to this action chiefly, and approximate in their nature to death from prussic acid. Christison gives special prominence to the nervous symptoms, and describes them as immediately following the poison, as in the case just narrated; other writers describe them as setting in after the action on the mucous membranes is thoroughly established. In my case the nervous symptoms and the corrosive began, continued, and ended together.

Chatteris, Cambridgeshire.

CASE OF TUBAL FŒTATION.*

By JOHN MORLEY, Esq., Barton-on-Humber.

On January 13, 1849, 11 P.M., I was requested to attend H. T, aged 27, single woman, a servant at Barton-on-Humber, who, after having finished her work in apparent health, proceeded up stairs at 6 P.M. to wash herself, and was suddenly seized with acute pain in the abdomen, and faintness, which caused her to fall on the bed; she vomited once what appeared to be rice-pudding, (part of her dinner taken at one o'clock). At seven, she asked her mistress to milk the cows, as she felt too ill to get up. About half-past ten she became suddenly worse, and requested that medical assistance might be immediately procured, as she felt as if she should die.

I found her at eleven, undressed, on the bed, lying on her left side; surface universally cold and blanched; lips blue; mucous membrane of mouth exsanguine; respiration performed slowly, and with great effort; pulse at wrist almost imperceptible; impulse of heart very faint. She lay with eyes closed, yet perfectly conscious, and able to give an account of the commencement and progress of her case. The slightest attempt to raise her head from the pillow, (as when taking stimuli, which she partook of freely without increasing the abdominal pain), caused her to faint. She complained of severe pain in the abdomen, which increased at intervals. From the appearances presented by her breasts, I asked if she did not consider herself to be in labour, which she did not, although she admitted that she had given birth to one child eleven years ago, and had not been unwell since the beginning of last August. On examination per vaginam, I found the os uteri closed, the cervix in the unimpregnated condition. On making as careful an exploration of the abdomen as the state of the patient would admit of, no gravid uterus could be felt. On gently percussing the parietes, fluctuation could be detected on the left side. In the right hypochondriac region was a large tumour, which could be easily moved about. Stimulants were freely administered, and warmth applied externally, without, however, the slightest benefit; she gradually sank, and at two A.M., of the 14th, expired. Immediately after death I

* The preparation connected with the above case was shown at the Anniversary Meeting at Hull, but the case has only recently been forwarded to us.—Ed. J.

was able distinctly to make out the form and size of the tumour, which I considered to be a fœtal head.

Her friends having granted permission for an inspection of the body, I proceeded, in company with my friend, Mr. W. H. Eddie, surgeon of this place, to make it in the afternoon. *Abdomen:* on reflecting the parietes, we found the viscera concealed by a large coagulum of several pounds weight, together with some pints of fluid blood in the peritoneal cavity; having removed these, the first object which struck our attention was a male fœtus, (between the 5th and 6th month of gestation), with its head just below the margin of the liver; on tracing the funis we found that it terminated in the placenta, still partly attached to the interior of the parietes of the left fallopian tube, which was rent throughout, nearly the whole of its extent. The uterus was little, if at all enlarged; its cavity lined by the decidua, and the os plugged with mucus.

ON THE ACETATE OF LEAD.

By REGINALD BURRIDGE, M.D.,

SENIOR-PHYSICIAN TO THE SOMERSET AND TAUNTON HOSPITAL.

The excellent practical paper by my esteemed friend, Mr. Sweeting, of Abbotsbury, upon the above subject, in the last number of our *Provincial Medical and Surgical Journal*, would seem to call for individual experience of the remedy therein treated of. I had hoped that the experience of the last twenty years sufficed to place, beyond a doubt, the extreme value and the comparative innocuousness of the acetate of lead, where used, under ordinary precautions, as a therapeutic agent. For several years I had an opportunity of seeing this remedy largely employed, in doses of five or eight grains, by the first toxicologist of the day—Dr. Christison, and hence became early and usefully familiarized with its several properties.

In the year 1837 the town and neighbourhood of Taunton was invaded by an epidemic dysentery, in which the superior value of lead, in my hands, was most conspicuous. I shall not scruple to give an outline of two cases illustrative of its efficacy, and of Mr. Sweeting's main position; the one from my private case-book, the other from hospital practice.

In August, 1837, I was attending, with a very respectable surgeon of this town, a young lady of strumous habits, who was labouring under the then prevailing epidemic, or rather, perhaps, endemic. We were summoned very early one morning with an alarm that the patient was bleeding to death. The surgeon was prevented, by a midwifery engagement, from accompanying me—a distance of three miles—but I fortified myself from his surgery with half an ounce of acetate of lead and a bottle of compound spirits of ammonia. Arrived at the house, I was shown three evacuations, the two first containing about a pint of loose coagula each, the third being a solid coagulum, about fourteen inches long, and forming a complete mould of the colon. The patient was cold and pulseless; the eyes fixed and glazed; the tongue cold, and the cold dews of death had already descended upon her. The anæmic state was very marked, including the rare and sighing, almost sobbing, respiration. In this dilemma I gave two teaspoonfuls of brandy, with a few drops of Spt. Ammon. Co., rapidly followed by a scruple of the acetate of lead. In the meantime I had prepared a small starch enema, with a half-drachm of the acetate. Within less than half an hour the next coagulum passed, and I immediately administered the enema, and gave the second scruple of the acetate. One hour afterwards I gave a third scruple, and I had the happiness to see my patient convalesce without further hæmorrhage, without any unpleasant symptom, and I can add that she is now alive, and a most useful member of society.

Later in the same year I was called upon to advise for an old soldier of the Coldstream Guards. This poor fellow passed daily large sphacelated portions of the colon and rectum, the mutilated intestine protruding through the anus in large gangrenous shreds, like the fingers of a glove. He had been treated with mercury, and finally with large doses of crude opium, without the smallest relief. Here eight grains of the acetate every three hours acted like a charm, combined with the local use, and I meet the old man now, in my daily walk to the hospital, as hale and hearty as an octogenarian can be.

I have selected these two cases, not as those in which the largest amount of the remedy has been well borne, but as those in which full doses have been followed by the happiest possible effects; indeed, during twenty-one years' ample experience of this remedy, I have never witnessed a single untoward symptom from its therapeutic use.

I have stated above that such has been the universal effect of the remedy "*in my hands*," and I did so for this especial reason:—During the endemic of 1837, several of my professional brethren, hearing of my successful mode of dealing with it, inquired the particulars. The remedy came into general use, but produced such irritating and unfavourable symptoms, in doses of *one or two* grains, the limit to which it was THEN judged safe to restrict it, that it was, after a short and unfair trial, abandoned.

The only point on which I presume to differ from my old and excellent friend, Mr. Sweeting, is this—that of combination. In accordance with the practice of Dr. Christison, and the rule laid down by the late Dr. A. T. Thomson, of University College, I always give acetate of lead in a FLUID form; *never* without acetic acid, and very rarely indeed without Battley's Liq. Opii Sedativ. My large hospital and other opportunities have enabled me to test the relative value of lead and opium, separately and conjointly. The result has, *cæteris paribus*, determined me in favour of the combination.

Taunton, June 12, 1851.

Hospital Reports.

BRISTOL ROYAL INFIRMARY.

SURGICAL CASES ADMITTED UNDER AUGUSTIN PRICHARD, ESQ., SURGEON TO THE INFIRMARY.

Case V.

Removal of Scirrhous Tumour of the Breast; Death from Cancer of the Internal Organs.

Mary Vining, aged 40, was admitted into the medical wards for the cure of rheumatic pains of the limbs, and was transferred, on the 11th of September, 1850, to my care, in consequence of the existence of a mammary tumour. She has had the swelling coming on gradually for four years, and it is now of the size of an orange; the skin is adherent to it, and the nipple retracted. There is a large and hard gland in the axilla. She was anxious to have the tumour removed, and an operation was determined on in consultation.

September 20th.—Chloroform was administered to her in her bed in the ward, under the superintendence of one of the surgeons, (as is always done in this hospital), and when thoroughly under its influence the bed was carried into the operation room. Here she at once became so blue and collapsed, without any pulse, that for some time she appeared to be dying, and she required a vast quantity of stimulus before the pulse became perceptible, and the little re-action that occurred was so long in being developed, that it was obviously unsafe to operate, and she was taken back to the ward.

After a few days she had completely recovered from the effects of the chloroform, and was willing to submit to the operation without any more attempts to produce insensibility, which she desired very much, but of which I should have been afraid to run the risk, and it was performed on the 24th of September. The tumour was removed entirely, with the skin to which it was adherent; it was isolated by fat from all the surrounding parts. Two hard glands were then taken from the axilla, by dragging them down and freeing their attachments by a touch or two with the edge of the knife. Five vessels required ligature, and five separate points of suture were inserted, and the whole supported by compress and bandage. She was very sick for a long time after the operation, in fact all the evening. She was ordered a prussic acid draught and an opiate at night.

25th.—Sickness relieved, but she has had no sleep, although she took ten grains of the Pil. Saponis Comp. She complains of a little pain in the arm.

26th.—The bandages were divided, and on the 27th, all the dressings and sutures were removed. The wound was found to have united by the first intention over the greatest part; the upper part of the anterior lip of the wound close to the axilla, rather overhung the posterior lip, and require considerable pressure to keep it in place.

From this time she went on pretty well, feeling her general health much improved. The lower part of the wound suppurated, and was long in healing. She was discharged on the 5th of November with the wound healed, but the upper part of the cicatrix was thick and harder than the rest. Upon a section being made, both the tumour and glands were hard and fibrous, presenting the usual appearance of hard carcinomatous disease. Nucleated cells of the ordinary appearance were very distinct; more characteristic, however, in the tumour itself, than in the glands; in the former many were fusiform and caudate, in the latter, they were all rounded. She subsequently attended as my out-patient, when I ordered her cod-liver oil, with a view to improve her general health, and early in the month of December her appearance had much improved; she was florid, and stated that she was well. On the 24th of December she was brought into one of the medical wards in a state of apoplexy, and died about an hour after admission without recovering her sensibility at all.

At the *post-mortem* examination, several cancerous cavities were found in the cerebrum and cerebellum, and she had cancer of the lungs and liver. The existence of the cerebral disease, in all probability, caused the alarming condition of the patient when under the influence of chloroform, and may have rendered her less susceptible of the action of opium, and, at the same time, it is more than possible that the removal of the external disease hastened the growth and development of the internal and more rapidly fatal disorder. A great peculiarity about the case is the rapid way in which she became fat and even plethoric after the tumour of the breast was excised.

Case VI.

Strangulated Femoral Hernia relieved by the use of Ice.

Susan Dixon, aged 73, admitted in the middle of the day, December 26, 1850, has a swelling in each groin, the left for many years, but that on the right side came down suddenly five days ago as she was coughing. She has had constipation for three days, and continued vomiting all the time. The tumours are small; the right one is tender to the touch, and the abdomen is a little distended. She insists that the swellings have nothing to do with her symptoms, and she never wore a truss. Pulse rapid and tongue foul. Gentle attempts at reduction were made, but without any good effect, the size of the tumour remaining the same. A bladder of ice was applied to the right groin, and a purgative injection was administered, which produced a slight evacuation. As she was not suffering very much, it was determined to leave her for a few hours, and she was given a draught containing forty drops of Battley's solution of opium. When I saw her in the evening, she had been keeping on the bladder of ice as much as she could, removing it now and then for a few minutes to relieve the pain of the intense cold; the tumour had become very much lessened, and her bowels had been freely relieved. The intestine had, in fact, gone back, when its size was diminished by the cold, and no symptom of obstruction remained. She was dismissed

cured a few days afterwards, with a truss for the right side. The swelling in the left groin could not be reduced.

CASE VII.—*Strangulated Femoral Hernia; Operation; Death from Peritonitis.*

Elizabeth Mountjoy, aged 69, admitted in the evening of February 5th, 1851, suffering from strangulated femoral hernia of the left side. She has had a rupture for many years and has worn a truss. It came down about twenty-four hours before her admission, whilst she had the truss on, and she was unable to replace it, and attempts made by a surgeon who saw her likewise failed. She has had vomiting and constipation since, and the abdomen and tumour are tender. The tumour is of the size of an orange, in the usual position. After the application of ice, and the gentle use of the taxis, to no purpose, the operation was performed at half-past nine P.M., the symptoms being very urgent. The sac was easily exposed throughout its extent and opened; it contained a considerable quantity of fluid, and about five inches of intestine, which had all the appearance at first of being a portion of the colon; it was thick (in fact emphysematous) and had lost its polish, and was very dark, but not uniform in colour; it felt, however, firm, and seemed to contain solid fæcal matter. I divided the structure at first upwards, but as this did not appear sufficient, some of the fibres of Gimbernat's ligament were cut through, and the intestine easily returned. Three sutures were inserted, and it was dressed with adhesive plaster, compress, and bandage. An opiate draught was given.

6th.—The bandage feels rather tight, and she has been vomiting a good deal; pulse 108; abdomen tender and tumid. To have the bandages divided, and a poultice over the abdomen, and another opiate. In the evening the pulse was 120, and she complained greatly of thirst.

7th.—Complains of flatulence and thirst; pulse 120; abdomen tumid; a little vomiting; Haust. Rhei c. Magnes. Carb.; very low and weak. In the evening her bowels were slightly opened, but she began to hiccup. To take four grains of calomel, and fifteen of Dover's powder to night.

8th.—Ol. Ricini, dr. ij., in the morning; stitches removed, and poultice applied to the wound. The castor oil acted, and she was better in the evening.

9th.—Abdomen tympanitic; pulse intermittent and very rapid; complains of intense thirst, and weakness; vomiting came on with great prostration the next day, and she died early on the 11th.

Post-mortem examination.—General peritonitis was found, producing partial adhesions of purulent fibrin all over the abdomen. No union in the wound. Eight inches of the ileum, near the valve of the cœcum were extremely dark, and at one point adherent to the inner opening of the crural ring. This portion of the intestine which had been in the sac was very much thickened, and worse than it was at the time of the operation, but not yet sloughing. A single tubercle surrounded by the fine cicatrix of a cavity was found in the summit of each lung. From the tightness of the stricture in this case, the intestine, although it was strangulated for twenty-four hours only, was so altered in structure, that its return to the cavity of the abdomen did not enable it to recover its natural state.

CASE VIII.—*Strangulated Femoral Hernia; Operation with Removal of Omentum; Recovery.*

— Callow, aged 59, has had femoral hernia of the right side for ten years, but never wore a truss, nor has the tumour entirely disappeared for some years. It came down on Monday, March 10th, while she was lifting a pail, and became strangulated. Attempts were made to reduce it, but in vain; and she was sent to the Infirmary about six P.M., on Wednesday, March 12th. The tumour was of the size of an orange, hard, firm, and tense, red, and painful to the touch, and œdematous. She was suffering from constant vomiting, and had constipation. Her pulse was very rapid. This case was very urgent, and the condition of the tumour precluded any but the most gentle efforts to reduce the protrusion. The operation was accordingly performed about seven P.M. I was unable to draw up the integument into a fold, in consequence of the œdematous and tense state of the skin; but, with this exception, the operation was performed in the usual mode—the sac opened and the stricture divided upwards and inwards. As soon as the sac was thoroughly laid open, some very dark bloody fluid escaped, but in small quantity. The contents were a coil of intestine, quite black, but smooth and polished, with a considerable portion of omentum, the lower part of which was thickened and hard, and had obviously not been in its natural cavity for some time. The intestine was returned tolerably readily, and the omentum tied in detached strips, so as to prevent hæmorrhage, and the hard part was cut off. The external wound was closed by sutures, the ligatures upon the omentum being fixed so as to keep the divided portion at the neck of the sac. An opiate was given to her afterwards.

13th.—Vomiting came on about seven in the morning, but it was relieved by some soda water and a small dose of Battley's sedative solution. Pulse 108. Flatus makes its exit from the lower part of the alimentary canal; some abdominal tenderness; tongue foul. To take a pill containing two grains of calomel and three of Dover's powder every four hours, and an opiate at night besides.

14th.—She is still occasionally vomiting green bilious matter from the stomach. Pulse the same. The wound is in a great measure united, except where the ligatures pass from the omentum. To have an injection of gruel containing an ounce of castor oil, and to leave off the pills.

15th.—The castor oil acted freely; in fact some diarrhœa exists.

16th.—Much the same, except that she complains of great weakness and faintness. Diarrhœa still persists. To take chalk mixture, and to have six ounces of Port wine in the day.

In the evening she was much better, and from this

time she gradually mended. The ligatures came away in about seven days, and she had one more attack of vomiting when the diarrhœa was checked. She was, however, for some time, troubled with flatulence.

CASE IX.—*Strangulated Femoral Hernia; Operation; Double Sac; Recovery.*

Jane Powell, aged 33, somewhat deformed in the limbs from rickets in early life, was admitted on Sunday, May 25th, about two P M., suffering from strangulated femoral hernia of the right side. She has had a hernia for many years, but has taken no notice of it. It became strangulated on the 21st, and since that time the bowels have been confined, and her stomach has rejected everything that she has taken. Her abdomen at the time of admission was tender and tympanitic. The swelling was a little tender, about as large as a walnut, and unusually movcable.

Attempts at reduction under the influence of chloroform were made, but without success, and the operation was accordingly performed. After dividing the skin by holding it in a fold over the tumour, another single layer was cut through, and the sac exposed, having all the usual appearances, thin and semi-transparent, and containing fluid. It was punctured and laid open, and what appeared to be intestine was exposed to view. The surface of this projection was smooth and shining, and obviously of a serous nature; but as it was not quite so uniform as the intestine is usually, and as I found it quite impossible to pass my nail, as a probe, under the stricture (for, in fact, by dragging upon the divided edges of the sac I could shew that the convex surface of the projection and the concave surface of the sac were quite continuous with one another), we examined it more closely, and discovered that there was a second sac within the first. This was punctured, some more fluid came away, and the intestine fully exposed. It was a small knuckle of intestine, very black, but quite firm, smooth, and polished. The stricture was extremely tight, and it was with the greatest difficulty that I could pass in the director to guide the probe-pointed bistoury. The intestine slipped in immediately the stricture was divided.

She was treated with opiates and quiet, and had no bad symptoms. The bowels were not moved on the 30th, and she, therefore, was given a dose of castor oil, which acted well and relieved her of some little discomfort which she suffered. She had retention of urine for three days.

June 10th.—The wound is now healed, and she is, in fact, cured.

The peculiarity of this case is, of course, the existence of a double sac,* which was distinctly the case, both being serous and shining, as the interior of a sac usually is. The sac of the hernia, after its first occurrence, must have become cut off from the general peritoneal cavity by adhesion, and another protrusion must have taken place at exactly the same spot. In this way the occurrence of a double sac is satisfactorily accounted for. The case is, however, one of extreme rarity, and therefore, well worthy of record.

* "Lastly, the parts are sometimes included in a double sac. M. Chevalier mentions two instances of this kind. * * Dupuytren met with a similar case:—"On opening the hernial sac a spoonful of fluid escaped, and a substance resembling intestine presented itself. This was soon found to be another hernial sac contained within the former. It was opened with great care, when about the same quantity of fluid escaped, and a portion of omentum and intestine were discovered.' "—*Lawrence on Hernia* (Art Femoral Hernia) p. 505.

This case described by Dupuytren was exactly the same as that of Jane Powell, which I have recorded, except that the latter hernia contained no omentum with the intestine.

Provincial Medical & Surgical Journal.

WEDNESDAY, JUNE 25, 1851.

AT page 361 will be found a communication from our valued associate Mr. NEWNHAM, on the subject of the Benevolent Fund, which he seems to fear will be prejudicially affected by the establishment of the British Medical Fund Society. In this anticipation we do not concur, for the difference between the purposes of the two societies is so great, that the one can scarcely clash with the other. The British Medical Fund is set on foot to afford to the *provident* member of our profession, the best means of insuring himself against premature old age, and his family from the misery and want which his early death (before sufficient time has elapsed to allow proper provision) so often forces upon them. On the other hand, the Benevolent Fund has the more widely charitable object of affording assistance to the *improvident*, or, more frequently, to their families, who are indeed objects of compassion; and the more so, because while we sympathize with them and afford them some little help in their day of trouble, we have not the unsatisfactory reflection that their misfortunes are caused by their own neglect.

In an overstocked profession like our own, it is frequently very difficult to make such a permanent provision by accumulated savings, as shall raise the family of a medical man above the probability of want, and there are even numerous cases of destitution, as Mr. NEWNHAM has so often told us, where an ample investment has apparently been made, and yet from some unlooked for misfortune all has been swept away. For the former of these cases the British Medical Fund is intended by its projectors to provide, whilst the latter is only met by the Benevolent Fund connected with this Association. It is not our object to attempt an encroachment upon what has now become peculiarly Mr. NEWNHAM'S province. To enter upon the objects of the

Benevolent Fund, with a view to give encouragement to its promoters, would be indeed "to gild refined gold," and we shall therefore take for granted that every one is satisfied with its objects, and the application of its means. All that is wanted, is "the sinews of war," and if the benevolent turn a deaf ear to Mr. NEWNHAM, we think it would be a hopeless task to follow in his wake.

The British Medical Fund comes before us, not to work upon our feelings as an object of our charity, but upon our reason, as a good and proper investment against the ills which flesh is heir to. It has been found that in other professions and trades insurance societies chiefly confined to a limited circle, have answered beyond expectation. The promoters of the British Medical Fund have thought that the plan might be advantageously applied to the medical profession, and they have therefore set the Society on foot on the same principles as many other and similar societies, with this additional advantage, which certainly appears a most tempting one, viz., that if after a certain time, an insurer should be unable to continue his payments, the Society will advance the sum necessary for that purpose. We conclude that it will be a *sine quâ non* that the insurer should be able to shew that the defalcation is only brought about by a temporary or unforeseen cause; but still the income of a medical man is so fluctuating, and is so often affected by illness, accident, or the numberless other circumstances influencing either his incomings or his outgoings, that this, *in theory*, is a great boon. We are afraid that in actual operation great difficulty will attend the application of the principle, but we trust that this will be eventually overcome.

Independently of this accommodation-clause, we do not see that there is much in the British Medical Fund to attract the attention. The average of life in our profession is known to be much below par, and therefore a Society composed entirely of lives of inferior value, can scarcely be expected to prosper as a speculation. The rates cannot safely be lowered, and we should almost expect that they must be increased in proportion to the diminished value of a medical life, as compared with others of the same age.

We would be the last to think of discouraging so laudable an attempt at ameliorating the position of our fellow-labourers, but after examining the question in every point of view, we are afraid that, as we have already remarked, the principle of accommodation under temporary difficulties, is the only one which is really offered by the British Medical Fund Society, on terms more advantageous than those of collateral societies, which have been long established and are perfectly secure. This accommodation can only be offered at some risk to the society, and that risk must be met by the profits, whilst we have shown that these cannot be expected to equal those of other societies, on account of the diminished value of the life of a medical man. Time will show what these profits will amount to, and to what extent they will allow of accommodation; but whilst we sincerely trust that the most sanguine anticipations will be fulfilled, we have thought it our duty to look upon the unfavourable as well as the favourable side of an undertaking, which certainly, if successfully carried out, will be of incalculable benefit to our profession.

IN reference to the remarks in our last number respecting the UNIVERSITY OF ST. ANDREW'S and its homœopathic graduate, we have the authority of the University Professors to state that they are taking such steps to rectify their mistake as seem best suited to the case. They also beg the perusal of Mr. HALE'S answers to their questions, which we give below. From these it will be seen that they are fully justified in believing that their diploma was justifiably bestowed.

UNIVERSITY OF ST. ANDREW'S AND HOMŒOPATHY.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—As I am led to infer by your leading article in your *Journal* of the 11th inst., that you charge the University of St. Andrew's with having conferred the degree of doctor of medicine on a homœopathic practitioner, I must beg you to publish the accompanying extracts from the answers given by the gentleman in question.

1. Name the emetics included in the Pharmacopœia, and state the doses in which they should be prescribed.

Answer. Ipecacuanha, tartar emetic, sulphate of zinc, and sulphate of copper. The doses are, of ipecacuanha, one scruple; of tartar-emetic, from one grain to two grains, acting better if in combination with ipecacuanha; of sulphate of zinc, from five grains to ten grains; and of sulphate of copper, from two to four or five grains.

2. Name the cases in which croton oil, aloes, jalap, gamboge, scammony, and elaterium, are specially applicable, and the form and dose in which *you* usually prescribe them.

Answer. Croton oil is administered in cases of very obstinate constipation, where other milder purgatives fail. It is used externally as a powerful means of counter-irritation.

Aloes is a useful purgative, where there is inertia of, or accumulation of feculent matter in, the sigmoid flexure of the colon, or in the rectum, and in cases of atonic dyspepsia, chlorosis, &c.

Jalap is a useful purgative in a variety of diseases, and is useful in cases of worms &c. in children.

Gamboge and scammony are allied purgatives, the former being rather more drastic than the latter.

The dose of croton oil is usually from the one-eighth to the one-fourth of a drop, according to the strength of the patient and the urgency of the symptoms. It is seldom given uncombined, and generally in the form of pills.

Aloes are given in pills, in doses of from five to ten grains—generally given in combination with scammony, calomel, or blue-pill. The decoction of aloes is a useful form, the dose being from half an ounce to an ounce and a half.

Gamboge and scammony, mostly in pills. Dose, from three to five grains of the former, and about the same of the latter.

Elaterium is a powerful hydragogue cathartic, useful in various forms of dropsy, in carrying off a large amount of serum from the intestinal mucous membrane. Dose, from one-sixth to one-fourth of a grain.

3. Write a Latin prescription for an expectorant mixture suitable for a case of chronic bronchitis; also for a warm aperient draught.

Answer.

℞ Misturæ ammoniaci, uncias quinque.
Tincturæ scillæ, drachmas duas.
—— opii compositæ, drachmas duas.
Misce. Fiat mistura. Capiat cochleare unum amplum bis vel ter in die.

℞ Decocti aloes compositi, drachmas sex
Tincturæ rhœi compositæ drachmam.
Misturæ camphoræ, drachmas quatuor.
Fiat haustus quamprimum sumendus.

4. Describe the treatment of iritis.

Answer. Mercury is the chief remedial agent, preceded by general or local abstraction of blood, if the strength of the patient will bear it. It should be given in small, frequently-repeated doses—half a grain or a grain of calomel. In small doses, first, because the system is more rapidly brought under the action of mercury when the doses are small and frequently repeated; and, second, because opium being contra-indicated, owing to its effect in producing contraction of the pupil, it ought to be given in doses that will not irritate the intestinal mucous membrane, producing diarrhœa, by which it would be carried out of the system, and not absorbed into it. In the strumous diathesis, the mercury should be given with caution; the doses should be smaller; and the bichloride often acts better than the chloride, in such cases. In the gouty and rheumatic diathesis, colchicum may be combined with the mercurial; and iodide of potassium is advantageous in some forms of the disease.

Besides the local treatment by leeching, the external application of belladonna and the exclusion of light are most important means to prevent the closure and adhesion of the free margin of the iris.

Counter-irritation may be demanded, in addition to other treatment.

5. Describe the treatment of acute laryngitis.

Answer. The treatment consists in active antiphlogosis, bleeding, leeching, &c.; the exhibition of mercury, (calomel, two grains, every two, three, or four hours;) but this may be preceded, in most cases, by nauseating doses of tartar-emetic (one-sixth to one-fourth of a grain), every two, three, or four hours. Leeches should not be applied over the larynx, owing to the difficulty of using pressure to stop the bleeding. Cupping to the nape of the neck is often better than leeches.

6. Describe the treatment of enteritis.

Answer. Antiphlogistic treatment here must not be so rigorous as in many other inflammatory affections, as there is a tendency to prostration. Local abstraction of blood, fomentations and poultices; the exhibition of mucilaginous drinks, with the cautious exhibition of calomel or hydrargyrum c. creta, in combination with opium or Dover's powder, include the principles of treatment. In this disease the exhibition of opium alone, with other means tending to diaphoresis, will often be sufficient; and, under this treatment, the action of the bowels will become restored without the use of purgatives, which, in this disease, are questionable in any of the ordinary forms.

7. Mention the treatment of the various forms of intestinal entozoa.

Answer. For the tape-worm; the best remedy for ejecting it is the oil of turpentine, given in doses of from three drachms to five drachms, with castor oil.

The lumbrici are expelled by many purgatives, which have the effect of producing mucous stools, as calomel and jalap, scammony, &c.

Ascarides may be got rid of by using, in addition to the above, enemata of infusion of quassia.

In all cases of worms, the tone of the digestive apparatus should be improved by tonics and alteratives.

Although the above extracts from Dr. Hale's written answers "specifying the mode of treatment he is in the habit of adopting, and the doses of the medicines which he prescribes," [see the note to our third Examination Paper], are, I think, sufficient to demonstrate that he cannot be a homœopath, I may add the additional evidence afforded by some portions of his oral examination in *materia medica*. Dr. Anderson was his examiner, but I was present, and noted down the questions and answers.

Dr. Hale stated that the doses of bichloride of mercury, when given as an alterative, varied from one-twelfth to one-sixteenth of a grain; that in croup (in the case of a child of three years of age), he would give one-sixth to one-fourth of a grain of tartar-emetic every four hours; and that in the pneumonia of adults he would give half a grain of the same medicine every three or four hours; that in prescribing hyoscyamus as a sedative, he gave eight or ten grains of the extract; and, finally, that he used arsenious acid in certain forms of skin disease (the squamous forms), and in diseases of a periodic type, his dose being one-sixteenth of a grain, or from five to ten, or fifteen minims of Fowler's solution.

I am, Sir, your obedient servant,
GEORGE E. DAY, M.D.,
Professor of Medicine.
University of St. Andrew's, June 7, 1851.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

APRIL 3RD, 1851.

MR. W. H. PARTRIDGE IN THE CHAIR.

Large bony Cyst in the Fallopian Tube, filled with Hair contained in fatty matter, in an old Woman; Cancer of the Liver; Diseased Gall-bladder; Gall-stones.—By Mr. CARTER.

A woman aged 66, mother of a large family, had been under the care of Mr. Carter, at the General Dispensary, for the last month. She used to complain of severe pain in the back and lower part of the bowels, when menstruating, for many years, and this pain in the back continued to the last. For the last two or three years she has had dyspeptic symptoms, pain and swelling in the region of the liver, and pain at the back of the

right shoulder. She has never been jaundiced nor yellow, until the *last three weeks* of her life, but the urine has been saffron coloured at times for the last twelve months. During nearly the whole period of my attendance she suffered from considerable nausea and from frequent retching. Her bowels were rather relaxed, her stools were reported to be brown, and during the last week, while jaundice was present, were stated to be *yellow*. Her urine was greatly loaded with lithates, was of a deep red, and stained the vessel. For a day or two during the last week, she had slight hæmorrhage from the uterus. The liver was felt very much enlarged and the edge much thickened; she had slight ascites, and the right leg was œdematous. About a fortnight before death she had an attack of severe pain in the right side, probably coincident with the effusion of the blood formed upon the liver. Her face bore the character of the cancerous cachexia.

On *post-mortem* examination the liver was found greatly enlarged, extending into the right illiac fossa; a recent coagulum of considerable extent was suffused over the convex surface of the right lobe of the liver; the proper tissue of the liver was almost entirely replaced by cancerous matter in masses of various size, so that scarce any of the normal tissue remained. The gall-bladder was greatly diseased; it was enlarged so as to be capable of containing a moderately-sized orange; its coats very thick and dense, and had the character of fibrous membrane; it was filled with inspissated mucus, so thick that none escaped when the gall-bladder was opened; and contained besides, three calculi the size of a walnut, and a vast number of small ones. The opening of the duct appeared at the upper part, quite patulous. The hepatic duct was large; the common duct was lost owing to the great brittleness of the tissues; spleen corrugated and tough; kidneys of usual size; a portion of one, by the microscope, was found to have its tubules filled with amorphous matter, abundantly mixed with small oil globules; only very few cells could be detected and they contained oil globules. There was considerable adhesion of the omentum to the edge of the liver, and to the intestines; some adhesions also of the intestines, recent and ancient; the abdominal cavity contained serum, in pouches formed by the false membrane.

In the right fallopian tube was a tumour of the size and exactly the shape of a fœtal head, of about seven months, saving that the bones of the face were wanting, it was oval and rather flattened; some masses of fat adhered to it. It was a complete case of bone, of about the usual thickness in the seven month's fœtal head, but had no vestige of sutures. It was quite filled with hair, contained in a mass of brownish yellow mortar-like matter, which was almost entirely composed of fat, as it was dissolved by ether and reappeared as fat by evaporation. The ovary lay close to the tumour; it contained a good deal of fat-like matter in its tissue. The other ovary was lost. The uterus contained a recent clot; it was not at all enlarged.

By the Microscope.—Examined by Dr. Russell, the wall of the cyst was found quite destitute of the structure of bone. The hairs were of a light brown colour, and one measured rather longer than two inches and a half. They tapered gradually to a pointed extremity, but none presented at the oposite end any vestige of a bulb, but were broken abruptly.

Scirrhous Tumour of the Breast undergoing Fatty Degeneration.—By Dr. Russell.

The tumour was presented to Dr. Russell by Mr. Percival, who had attended the patient and performed the operation. It was seated in a large mass of fat; it was irregularly rounded, and about two inches and a half in its longest diameter; it formed a lobulated prominence of a deep purple tinge above the mamma, the skin in that part being very thin, and entering into the state of ulceration. It had adhered closely to the fascia of the great pectoral. The circumference of the tumour presented a border of homogeneous tissue, partially transparent, from which an opaque fluid was expressed; this fluid was filled with cells, chiefly rounded or oval, with good sized nucleus and double outline, average diameter 1-1660th of an inch; the stroma of this portion of the tumour was composed of great abundance of fibrous tissue, crossed very irregularly by strands of like tissue, having the aspect, when out of focus, of large branching nerves; the tissue of the stroma did not present any definite arrangement of bundles. The main mass of the tumour was more opaque, and irregularly mottled with opaque yellow matter; in part it was of a rosy tinge, and presented patches of dilated vessels; under the microscope, it presented cells and stroma, as in the more transparent and homogeneous portion; but the great part of the tissue was obscured by a large abundance of molecular matter, and by a vast number of small fat globules, in some parts formed into little longitudinal groups following the course of the striæ of the fibrous tissue; there were besides, many large cells filled with fat globules and a dark opaque matter, of an average diameter of 1-1000th of an inch. Near to the root of the nipple the tissue of the tumour was quite diffluent, containing irregular broken down masses of cheesy matter, which, by the microscope, presented a still larger intermixture of fat than the portion just described. By acetic acid the fibrous stroma was rendered very transparent, and in parts became almost invisible.

The microscopic appearances indicated in a very interesting manner, the process of fatty degeneration in the tissues of the tumour, ending in complete destruction of the cohesion. The following history was furnished Dr. Russell by Mr. Percival:—

March, 1851.—Matilda Hall, publican, Cleveland, aged 53, a widow for the last four years, married thirty-one years, mother of ten children, husband when alive given to much drink, and in the habit of striking her heavily in his fits of drunkenness. Catamenia at 18; ceased to menstruate four years since. Could never suckle much on the right side; first found a hard lump on right breast, about June last, which increased rapidly. Had lancinating pain just before Christmas; says she believes the nipple was always drawn in; the prominence and blue appearance of the skin was situated above the nipple, a little towards the sternal aspect. There is no appearance of disease in the axilla. The

tumour is very moveable. She is of middle size, of loose, flabby make; has enjoyed tolerable health, but has a decided cachectic appearance. She does not inherit any malignant taint.

Removed by operation March 9th. She was very faint for some hours, more than twenty vessels required ligature, and she lost much blood, having troublesome cough, which disturbed her very materially.

Osseous Degeneration of Pericardium; *Heart adherent.* By Dr. Fletcher.

George Knight, aged 22 years, admitted into the General Hospital on the 28th February, 1851, under the care of Dr. Fletcher. Six months previously he was attacked with fits, during which he was insensible and much convulsed, and, being unable to follow his employment, went into the Wolverhampton Workhouse. These fits came on generally with severe palpitation and pain about the chest; and he was rarely more than a few days without one. Once, while wheeling a barrow, suddenly pain and beating began about his heart, and he almost immediately afterwards became insensible. About ten weeks ago he went into the Queen's Hospital, where he was under the care of Dr. Davies, who told him his heart was very much diseased, and (it is said) was of opinion that he might die suddenly. He remained in that hospital about three weeks. He complained of rheumatic pains in different parts of the body, but there were not any signs of inflammatory action nor heat of surface; and said that he had been affected with disease of the heart, of which the only signs were more extensive dulness upon percussion in the pericardial space, and the pulsations were more diffuse over that region. The valvular sounds were regular and normal. He went on very favourably during the earlier part of his stay in this hospital, under an alterative plan of treatment, but always had a slightly-puffed and livid aspect, and occasionally complained of pain in the chest. On the 9th of March he said he felt worse, and complained of pain in his left side; and his pulse was observed, for the first time, to be intermittent, which it continued up to his death. He seemed to be affected with the catarrhal epidemic, in common with many other patients in the ward, and was then treated upon a diaphoretic plan. On the 21st of March he was as well as usual until about eleven o'clock, A.M., when a patient in a neighbouring bed heard him rattle in his throat, and observed him to be slightly convulsed; his face was livid, and in a few minutes his pulse disappeared. He only breathed once or twice after he was seen by the resident medical officer.

Post-mortem Examination twenty-four hours after death.—The external appearance of the body was that of a stout muscular man. On sawing through the calvarium the bony structure was, if anything, softer than natural, but about the normal thickness. On removing the calvarium, the dura mater was slightly thickened over its whole surface, but the part covering the superior portion of the right hemisphere of the brain was at least three times its usual thickness. The dura mater being removed, the whole of the superior portion of the brain in the subarachnoid space was occupied by an opaque milky-looking fluid, which, on examination, appeared gelatinous. The membranes were stripped off with much greater ease than usual, and were much congested. A transverse section being made, the lateral ventricles were greatly distended with fluid to the amount of about six ounces. The brain itself was about the normal consistence; there was a cyst in the choroid plexus of the right side about the size of a horse-bean, the inferior surface of which was quite cartilaginous, or still more nearly approaching ossification. The weight of the brain was three pounds and a half. On opening the thorax there were very slight adhesions on the anterior surface of the left pleura, the lungs themselves in the posterior portion were much congested, in other respects healthy, weighing two pounds fifteen ounces. The pericardium was exceedingly firm in its structure, and in several parts was completely ossified in patches. As well as being ossified, there were some parts much more thickened than others, but three distinct ossific patches were to be found, one on the right side of the heart, about the sulcus between the right auricle and ventricle, a second clipping the apex of the heart anteriorly and posteriorly, and a third about the middle of the posterior portion of the left ventricle. There appeared before the heart was opened, to be an aneurism of the left ventricle; but after the section was made no abnormal appearance was noticed; the valves were healthy, but the external appearance spoken of was accounted for by the presence of one of the ossified portions of the pericardium pressing upon the apex, and so forming a vast sulcus. Weight, with pericardium, two pounds two ounces and a half. The liver was much enlarged, contracted at the edges, presenting a nodular appearance externally and internally, and weighing four pounds thirteen ounces. The spleen was much enlarged and congested, weighing one pound twelve ounces and a half; the pancreas weighed about four ounces; the kidneys were both much congested and enlarged, and contained a smaller portion of the pyramidal structure than usual, right weighing eight ounces and a half, left nine ounces. There was a slight effusion into the abdomen, but the intestines were healthy.

Scirrhous Tumour of the Mamma.—By Dr. Russell.

This specimen was given Dr. Russell by Dr. Mackay, who removed it by operation. The tumour occupied the mammary gland; it was of considerable size, of pearly aspect, and firm consistence. The fibrous bands very distinct, in one part they formed strong laminæ, penetrating, side by side, to some depth into the tumour; they enclosed a softer matter, quite distinct, which projected from the surface in the manner of globules of fat. An opaque fluid was expressed from the tumour; it contained a large abundance of cells, delicate, irregularly rounded, with distinct double outline, and bright nucleus, in diameter from 1-1667th of an inch downwards. The cells manifested great disposition to cohere, scarcely a single one floated loose; there were, besides, large cells, loaded with fat globules. The fibrous lamina was composed of strong fibrous tissue, imperfectly fibrillated, becoming transparent by acetic acid; the firm adhesion of the cells to the fibrous stroma, and to one another, increased the proportion of the solid frame-work of the tumour; in parts they had a kind of

imbricated arrangement, so as to arrange themselves somewhat into bands or ridges.

Dr. Mackay gave the following history of the case:—Mrs. S., aged 45, thin, but healthy looking, the mother of several children. She always menstruated naturally. She perceived a small lump in the left mamma eight months ago; it increased steadily, and latterly was the seat of lancinating or darting pains. It was moveable immediately under the nipple, which was unaffected, and seated over the centre. The tumour was removed by excision.

SOUTH WESTERN BRANCH.

The Annual Meeting of the South Western Branch of the Provincial Medical and Surgical Association, was held at Moorshead's Royal Hotel, on Tuesday, June 17th.

At 12 o'clock, P. W. Swain, Esq., of Devonport, the President-elect, took the chair.

The following were amongst the gentlemen present:—P. W. Swain, Esq., Devonport, the President; Dr. W. D. Kingdon, Exeter, the Secretary of the Association; George Rolston, Esq., Devonport; T. Rutter, Esq., Devonport; Dr. E. T. Roe, Plymouth; W. J. Square, Esq., Plymouth; Dr. Rae, Royal Naval Hospital, Stonehouse; Dr. Pennell, Venbridge House, Dunsford; Dr. Palmer, of the Lincolnshire County Lunatic Asylum; R. F. Burrough, Esq., Dartmouth; Dr. Shapter, Exeter; Dr. Nankivell, Dr. Hall, and T. Hunter, Esq., Torquay; Dr. Row, Devonport; R. Langworth, Esq., Plympton; G. Dansey, Esq., Devonport; Dr. Cookworthy, Plymouth; Dr. Tripe, Plymouth, &c., &c.

The Chairman, after expressing regret that more of his professional brethren were not present, addressed the meeting to the following effect:—

The greatest pleasure I derive from the honour done me of placing me in the president's chair, is the satisfaction of welcoming to Devonport, for the first time, any member of the Provincial Medical Association. The medical mind, so to speak, is always an actively-inquiring mind, and there are many objects in this town and neighbourhood eminently calculated to repay curiosity, and to gratify a thirst for information, be it ever so intense. I need not advert to the picturesque character of our panorama, nor observe that our arsenal is remarkable as well for its extent and efficiency as for the beauty of its situation. We can at once turn the eye from the oaks and pines of Italy and Norway, yielding to the saw and hammer of the artisan in our Dock-yard, to their congenus flourishing in all their verdure on the slopes of Mount Edgcumbe, while the mighty structures of stone now complete or in progress, suited to control the storms, or as recipients to the worn and weary vessel, may be looked upon from the very quarries whence they sprung; and which, whether on the granite peaks of Dartmoor, or in the variegated mountains of primitive limestone, serve to enhance the beauty of our prospects, and, as it were, to make a back ground to the extensive picture. The votary to natural history may find all the primitive forms of life in our zoophites and corals, and study the early manifestations of that vital energy which it is the business of our lives to modify and repair; nor can we fail, as phynologists, to value such illustrations of invincible, unextinguishable life as may be seen in the effects produced by the tiny *pholus saricava*, boring into our Breakwater, and making the timid tremble for its permanency. I must, however, quit these interesting topics with the observation that it will give me the greatest pleasure to act as guide to any of the members who will remain after the meeting, and who may wish to examine either our scenery, or natural history, or public establishments, to all of which admission is easily obtained.

The town of Devonport is not remarkable for its public medical institutions; although numbering forty thousand inhabitants we have no public hospital, a want however, in some measure, supplied by the contiguity of the South Devon Hospital, located in the neighbouring town of Plymouth. The two State hospitals, naval and military, connected with the port and garrison, receive of course, all the sick and hurt from either service, and are served by a staff of naval and military medical officers. The Military Hospital is remarkable in being the establishment where, many years ago, the first successful amputation at the hip-joint was performed in England, and by a rather singular coincidence, the *last* operation of the kind was conducted with wonderful dexterity and success, by my friend Mr. Whipple, at the South Devon Hospital, about two years ago. The patient is quite well, and though so extensively mutilated, pursues his calling as a butcher with much activity. All extensive accidents occurring in the Government establishments are attended immediately by the surgeons of those establishments, but sent for cure to the Naval Hospital. Our public Dispensary is situated in Chapel Street, and is an institution of extensive usefulness. Its duties are effectually carried out by six surgeons, two physicians, and two apothecaries; to the latter an honorarium is presented when the funds of the institution are flourishing.

Having said thus much of the public medical establishments connected with Devonport, I will pass in review a few circumstances of individual interest in its medical history.

Since the last meeting of this Association death has closed the career of a gentleman, who, while alive, formed a link of connection between the days of Hunter and our own. I allude to the late Mr. Dunning, who practised in this town for the better part of nearly half a century, and in the early part of the present year closed a long life of successful utility at the advanced age of 90 years. It is interesting to contemplate the career of our own body, which began in the last century, and to compare its difficulties and its advantages with those of the present day. No cloud of medical periodicals then diffused these showers of information which now irrigate and enliven our present labours. The metropolis, visited but for a short period for matriculation, henceforth became a place only to be heard of by the general practitioner. Communication of all kinds was costly. One can hardly realize professional life unaided by the railway, the electric telegraph, and the penny-post. Gutta percha was not known then; and I have heard the subject of the

present notice say that he remembered not being able to buy a bit of Indian-rubber in Devonport.

In such a state of society no small amount of energy was needful to stimulate the labouring practitioner beyond a course of ordinary routine; and hence I always look back on Mr. Dunning's life with a feeling akin to veneration.

Many subjects attracted his attention and stimulated his pen. He wrote numerous papers on medical subjects, but particularly one on Influenza, perhaps the earliest notice of that disease in modern medicine. His main energy, however, was displayed in the advocacy of Vaccination. Although they never met, he became the constant correspondent of Jenner, and their letters were published in the life of the great vaccinator, by Dr. Baron. I have heard Mr. Dunning narrate with great glee the following anecdote:—He had demanded from Jenner a supply of vaccine matter, which was announced by the latter as being on its way. His list of children was made out in anticipation, when behold the vaccine arrived, not on points or glasses, but in the shape of a large Cheshire cheese.

I have seen caricatures of the day, in which children were represented with cow's tails and hoofs growing from different parts of their body. Everything which prejudice could do by ridicule or otherwise to oppose vaccination, was launched against it, and it must have required no small degree of courage for a man dependent on public patronage to have risked at once his reputation and his livelihood in maintaining a practice, the novelty alone of which would make it suspected. Well, however, did our departed friend sustain the honour of his cloth. He converted his professional brethren to his own views, and led the van in satisfactorily establishing the practice of vaccination in this neighbourhood. I knew Mr. Dunning only in his latter days, when he was enjoying the toil-earned fruits of his early years; and perhaps none was so sweet to his mind as the reflection that he had lived to see the triumphant success of his early *protegé*. Towards the close of his life he lost his vision, but he never lost his enthusiastic devotion to the medical profession—nurtured and tended by affectionate children, he still, through their means, with continued energy adverted to his early pursuits—and until his latest hours, when the golden bowl was all but broken, his mind loved to roam amidst the productions of his more vigorous days, to fight again his controversional battles, to recall the triumphs of his art, and to see around him the professional friends, many of whom he had assisted in bringing into the world.

Happy, indeed, will be the lot of all of us, if we may anticipate such a closing scene. Full of years, and surrounded by respect, *he died*, and leaves deeply impressed on our minds the picture of an honourable, courteous *old English Gentleman*.

I will next advert to a circumstance highly honourable to the surgical history of Devonport:—

In the present day, I presume any ordinary practitioner would undertake all the operations in surgery. But forty years ago many of them were incomplete in their details, and uncertain in their result. This was particularly the case with regard to lithotomy. The best method for its mechanical performance was undecided, nor had experience yet definitely shown what were the causes of its frequent failure. Undeterred, however, by these difficulties, my old friend and master, Mr. Tripe, the elder, proceeded to operate on the first case that presented itself, and between the years of 1806 and 1827, in his private practice alone he operated on twenty-five cases, out of which three only died; he anticipated the plan now universally adopted, namely, that of using a simple long scalpel, and discarding all the paraphernalia of beaks and gorgets. I have examined all his calculi, which he kindly placed at my disposal to-day, but which I did not think time would allow us profitably to examine. It gives me much satisfaction that an opportunity is now afforded me of recording the brilliant example of provincial surgery I have alluded to, and at the same time to declare that I feel great pleasure in having Mr. Tripe as a fellow-townsman, and still more in the recollection that from him I derived my first lessons in surgery.

The next subject which I shall briefly notice, is connected with the medical history of Devonport, inasmuch as the gentleman, who will presently elucidate it more completely, is a native of the town, and passed the first years of his professional life under the tuition of my friend, Mr. Welch. Every one who has paid any attention to the subject, must have felt that the frequent assertion, that insanity left no morbid appearances in the brain, must be the result of inattention, oversight, or of our limited knowledge on the point. This subject appears to be about to be cleared up to a very great degree. Dr. Palmer has turned his attention exclusively to the subject of insanity, and through a numerous series of examinations, has detected a positive morbid change in the grey matter, which forms the periphera of the cerebrum. A case occurred to myself a short time since, where I had the opportunity of examining the brain of a patient, who had, during life, manifested many symptoms of insanity. Dr. P. was fortunately in the neighbourhood, and demonstrated to me so clearly the appearance in question, that I have no doubts on the subject. Should his views prove correct, they will have a double value, inasmuch as they will go far to show that we have been correct in surmising that the grey vesicular matter of the brain, is the active agent in producing intellectual phenomena. I have great pleasure in introducing Dr. Palmer to the Association, who, I am sure, will listen with much interest to his communication.

One other subject only will detain you from the general business of the meeting; a motion will be laid before you expressive of your approval of the memorial presented to Sir G. Grey, by the General Council of the Association regarding the sale of arsenic.

It gives me sincere pleasure to congratulate the members on the amicable termination of all discussion on the subject of Medical Reform. Mutual concessions have produced this happy result, and we may hope that we shall find that consideration from the rulers of our own old College of Surgeons, the withholding of which would have led to the establishment of a new, and I must confess, to me, an equivocal establishment.

The possession of diplomas and honorary titles is a temptation which often has too great weight with all of us. As tests of our capability to undertake medical practice, these distinctions are valuable, and the public

have a right to know who has studied and who has not. We cannot, however, nor may we compel them to distrust the pretensions of quackery, which unfortunately, in some shape, too often is found not incompatible with very honorary and high sounding titles. There is, however, one thing for which no titular distinction can be a substitute, and without which, we can never hope to command the respect of our fellow citizens, whether they be our wealthy patrons, or only dependent on our often-tried generosity. That one thing, gentlemen, is a high sense of the obligations imposed on us by our professional relations to each other. Nothing can tend to undermine the confidence of the public generally in the professors of our art, as the observation of the frequent disagreements between ourselves. And, gentlemen, my adherence to the Provincial Medical Association, rests on the belief that it is eminently calculated to knit us together in the firm bonds of friendly union. Our interests are the interests of the public, because, the more respectable we are, the greater is the guarantee that their reliance on us will not be misplaced. In no country in the world does the profession as a whole, take rank in society as it does in England, and I am bold to say, that in no class of Queen Victoria's subjects will be found more loyalty, greater love of order, or less infidelity to the trusts devolving upon them.

Impressed with such convictions, gentlemen, the integrity of our body becomes a high stake to maintain—its honour a bright light to cherish. Hand in hand, then, or as our Cornish friends will say, "One and all," let us strive by our own individual and collective efforts, to win the respect of the public, and of each other; and let each one of us feel—

> "To thine own self be true,
> It needs must follow, as the night the day,
> Thou canst not then be false to any man."

On the conclusion of his address the Chairman was heartily applauded.

On the motion of T. Rutter, Esq., seconded by R. F. Burrough, Esq., it was resolved,—"That the next annual meeting of the South-Western Branch of the Provincial Medical and Surgical Association, be held in Exeter.

P. C. De La Garde, Esq , of Exeter, was, on the motion of Mr. Burrough, elected president for the next year.

Dr. William Dashwood Kingdon was re-elected secretary, by acclamation; and the usual election of five new members of the Council (of fifteen) was made.

On the motion of Dr. Pennell, seconded by Dr. E. T. Roe, of Plymouth, a resolution was adopted, approving of the course taken by the Council of the Association, in forwarding an Address to Sir George Grey, in favour of the discriminate sale of arsenic, and asking the interposition of Government to prevent the evils which had resulted from a want of proper care in the vending of that article.

In the course of the conversation upon this point it transpired, that the principal feature of the measure of the Government was the establishment of a register, in which the names of every person buying arsenic would be registered, and that this measure was to be regarded as simply of an iniatory character, and as likely to lead to something more decided, and more efficient.

Dr. Palmer, of the Lincolnshire County Lunatic Asylum, then read a paper of some length, which he illustrated by diagrams and microscopical preparations, elucidating the essential pathology of insanity, and clearly demonstrating that this malady depends solely on the state of the cortical grey matter of the brain.

Some conversation followed Dr. Palmer's very able paper, and after an examination of his microscopical preparations, the members of the Association present appeared to coincide in the opinions he had advanced.

The President referred to the views developed by Dr. Palmer as being of the very utmost importance in relation to the treatment of insanity, and expressed a hope that they would lead to results which would enable the profession to cope with certain phases of that mysterious affliction, with greater probability of success than they previously could do.

Dr. Rae, of the Royal Naval Hospital, Stonehouse, brought under the notice of the Association the use of the tourniquet forceps in arresting hæmorrhage from wounded arteries, and also a new apparatus for treating fractures of the lower extremities.

W. J. Square, Esq., of Plymouth, mentioned an interesting case of wounded radial artery.

After the conclusion of the business and discussions, a number of the gentlemen present sat down to a dinner, and in the evening there was a general *conversazionie* of the members of the profession of the three towns, and the visitors who had come to attend the meeting of the Association at Mr. Swain's residence, in Ker Street. The splendid array of microscopes with which the rooms were plentifully furnished, were put into frequent requisition by the visitors; and the meeting, which was characterized by a warmth of cordiality which was quite refreshing, as a scientific reunion has been rarely equalled in the provinces.

NORTH WALES BRANCH.

At the annual meeting of the North Wales Branch of the Provincial Medical and Surgical Association, held at the Crown Inn, Denbigh, on Tuesday, the 17th of June last, the following resolution was unanimously agreed to:—

Moved by Dr. Chambers, seconded by Price Jones, Esq., and carried unanimously,—

"That the members of the North Wales Branch of the Provincial Medical and Surgical Association assembled at their annual meeting in Denbigh, having taken into consideration the subject of Medical Reform, do approve of, and entirely concur in, the steps taken by the Council of the Parent Association, as expressed in the memorial recently presented to Sir George Grey; and unite in hoping that the present unsettled and divided state of our profession may speedily receive that attention and wise legislation which the importance of the subject demands.

"(Signed) R. Lloyd Williams, President.

"E. Williams, } Hon.
"D. Kent Jones, } Secretaries.

"June 17, 1851."

[The remainder of the Report will be inserted in the next number of the *Journal.*]

Foreign Department.

FRANCE.

Extravasation of Blood behind the Uterus.

M. Monod presented a pathological specimen exhibiting an example of this extravasation. The patient had complained of extreme pain in the pelvic regions. M. Monod had at first thought that the case had been one of retroversion of the uterus, but on closer examination he discovered, behind the uterus, a voluminous tumour presenting fluctuation. A puncture was made, and gave exit to blood. The puncture was repeated, but the inflammation was not arrested, and the patient died. On the examination of the body a large quantity of blood was found collected behind the uterus.

M. Nelaton stated that he had several times observed these cases, and had drawn attention to them, under the name of retro-uterine hæmatoceles. The seat of the disease is behind the uterus, extending from the insertion of the vagina into the neck of the uterus upwards, without limit, in some cases filling both iliac fossæ, and reaching to the umbilicus. These tumours are only met with in menstruating women, and under various states of health, most usually where menstruation is difficult, and attended with pain. In one case it appeared upon a sudden suppression of the catamenia. Frequently these patients suffer also from hæmorrhage by the vagina. The course of the disease had been noted by M. Nelaton in seven cases. In one a simple puncture was followed by complete cure. In the second a cure also followed after several serious accidents. In the third, which M. Malgaigne had mistaken for a case of fibrous tumour, extensive incisions were made in the uterus, and the case ended fatally. The fourth and fifth were cured by incisions. In the sixth the blood was discharged by the rectum, and the patient recovered. In the last instance complete absorption of the blood had taken place. M. Nelaton observed, that it was not possible to say whether the extravasation was within or external to the peritoneum.

Varicose Dilatation of the Vessels of the Prepuce.

M. Beau (*Revue Medico-Chirurgicale*, Janv.,) describes a condition of the prepuce which has not been noticed by previous writers, and which depends on a varicose dilatation of the lymphatics of the part. This lesion appears as a transparent cord, resistant and hard to the finger. The fluid which it contains is perfectly limpid. The disease generally appears suddenly after friction of the prepuce during coition, and after a time it is produced by simple erection. At first it speedily subsides after the exciting cause is removed, but eventually it becomes permanent, and in some cases becomes as large as a crow quill. The treatment, when recent, is confined to simple measures, such as demulcent or astringent lotions. In the chronic state it may be cured by causing obliteration of the duct, by means of a thread passed through it.

Syphilitic Growths around the Glottis ; Suffocation.

M. Bourquet (*Gazette Médicale*, Avril 26) relates the case of a female aged 28, who was admitted in 1841, into the hospital at Aix, with tertiary symptoms. There was no question as to the nature of the disease, the patient avowing that she had chancres several years previously. She recovered under iodide of potassium, and was discharged.

In 1843 she was again admitted with symptoms of phthisis, together with suffocative dyspnœa and partial loss of voice. All treatment was unavailing and the patient sunk in a paroxysm of dyspnœa. After death, vegetations precisely similar to those which are seen round the anus or between the glans and prepuce, occupied and almost obliterated the chink of the glottis. They sprung from a little above the cordæ vocales. The lungs were perfectly sound.

Excision of the upper three fourths of the Humerus.

By M. Seutin.

In the cases of excision of joints hitherto reported, the portions of bone removed have been limited to the articulating surface. The following case is therefore interesting as exhibiting an instance in which a large portion of the humerus was successfully excised. The case is recorded in the *Revue Medico-Chirurgicale*.

A boy, aged 14, was admitted into the hospital to which M. Seutin is attached, in a state of utter prostration. He had fallen on his shoulder some time previously, and two months afterwards the joint became painful. On admission the left shoulder was enormously swollen and painful on pressure. The swelling extended to the acromion process, as far as the inferior third of the arm, and was evidently filled with fluid. An incision gave issue to a large quantity of purulent fluid, and the head of the bone could then be felt to be completely denuded of periosteum, and carious throughout the extent of the abscess.

It was obvious that no means could ensure the recovery of the patient until the diseased bone was removed either by amputation or resection, and the latter, after due consideration, was decided upon.

The incisions which were made to evacuate the pus were accordingly enlarged, (the patient being chloroformed) and the head and entire shaft of the bone to within two inches of the condyles was exposed. The diseased portion was then removed with a chain saw. The arm was then dressed and placed in a condition which precluded movement in the elbow and shoulder.

The portion of bone removed measured five inches and three quarters. The operation was followed by some reaction; but soon moderated. The patient was ordered cod-liver oil with generous diet, and in three weeks the wound had healed, with the exception of a small fistulous opening. In less than three months, bony matter had so far replaced the excised portion of the humerus, that the patient had a tolerably useful arm.

GERMANY.

Scarlatina.

Dr. Volz has recorded his experience of a severe epidemic of scarlatina in Carlsrhue, from which he draws the following deductions:—

1. The extent and redness of the eruption are not in direct ratio to the severity of the disease.

2. The proximate cause of the exanthem is a stasis in the cutaneous capillaries.

3. The exfoliating scales of epidermis do not transmit the contagious principle of the disease.

4. The mucous membranes undergo the scarlatinous eruption equally with the skin.

5. The lesions of the throat are of three varieties,—catarrhal, inflammatory, and gangrenous.

6. The inflammation of the parotid which accompanies scarlatina, seldom terminates in suppuration; that which follows the subsidence of the exanthem, often suppurates.

7. In the consecutive anasarca the alterations in the kidney are secondary, and depend on the change in the composition of the blood.

8. Death may occur in scarlatina from the following causes:—congestive apoplexy, suffocation, pyæmia, and anæmia.

Scrofulous Ophthalmia.

Dr. Spengler, (*Neve Zeitschrift für Med.*) recommends concine, the active principle of conium, in the photophobia which attends strumous ophthalmia. He prescribes the sixteenth of a grain, in six ounces of water, the dose being three tea-spoonfuls per diem.

General Retrospect.

PRACTICAL MEDICINE.

Symptoms of the Growth of Mediastinal Tumours.

In a clinical lecture on the diseases of the anterior mediastinum, Dr. Burrows points out the symptoms which indicate the presence of a tumour. He says that the earliest symptoms are those of irritation of the respiratory tube; then follow symptoms resulting from pressure on neighbouring parts. There are also the physical signs of some solid in the substernal region.

At first the patient has frequent attacks of urgent dyspnœa, such as is produced by pressure on the trachea and bronchi. These attacks are spasmodic, and the patient is supposed to be the subject of asthma. This distress may subside with or without expectoration. Auscultation at this period offers no diagnostic information. The frequent repetition of these attacks is soon followed by another train of symptoms which are the result of pressure on the vessels adjacent. The cutaneous veins about the upper sternum and one clavicle become more conspicuous than natural. This is more frequently noticed about the right side than on the left. The external jugular, the thyroideal, the mammary, and thoracic veins successively enlarge, remain constantly turgid, and become tortuous. If the course of the current, in some of the enlarged superficial veins on the thorax, be ascertained by means of pressure at different points, it will probably be discovered that the blood is moving in some of them in a retrograde direction to that which is natural. After awhile the superficial veins of one upper extremity become enlarged and conspicuous. This venous congestion is soon followed by œdema of the affected parts; some swelling is now observed on one side of the throat, about the upper portion of one side of the chest, of the upper extremity of the same side; and, lastly, if the patient be an adult female, by a gradual enlargement of the corresponding breast. This progressive œdema will at last extend to the face, particularly to the eyelids, which become puffy, while the expression of the eyes is peculiar. They have a glassy watery look, with rather dilated pupils, which state of the eyes is not unfrequently observed in cases where there is an obstruction to the passage of blood through the right cavities of the heart, and which condition of the iris may at will be temporarily induced by holding the breath for a long time and thus preventing the flow of venous blood into the thorax. And now, thirdly, we shall, by careful and repeated auscultation and percussion, detect physical signs which denote the presence of some solid beneath the sternum, which transmits the heart's sounds far beyond their proper limits, and which seriously impairs and modifies the healthy respiratory murmur in the upper lobe, and subsequently, perhaps more extensively, of one lung. The heart's sounds will be heard distinctly to the summit of the sternum, and to a varying extent, beneath the right clavicle, but without the peculiar blowing sound which is generally heard over a large aneurysmal sac. There is no pulsation in the intercostal spaces, nor over the sternum. The trachea is sometimes displaced, the vesicular sound is lost, and is replaced by bronchial breathing. As the case advances, these auscultatory signs become confirmed and extended. There is greater impairment of respiratory murmur. Percussion gives a dull sound all over the sternum, over the greater part of the affected side, while resonance is obtained by percussion in the axilla of the affected side. —*Medical Times,* June 7th, 1851.

SURGERY.

An account of a Fatal case in which Injury to the Brain was not detected during Life.—By George Anderson, Esq., 12th Lancers.

A trumpeter, of dissipated habits, was admitted into hospital in a state of confusion of mind, which was at the time partially attributed to drink. He had been fencing with a walking stick with one of his comrades, and had received a thrust in the face. A small punctured wound was observed in the left ala nasi, not larger than a leech bite. The part was fomented, and no unfavourable symptoms occurred on that day. The next day, however, stupor became more decided; subse-

quently he became violent, with stertorous breathing; right eye fully expanded, and staring, and its pupil greatly contracted; there was ptosis of the left eyelid, with great dilatation of the pupil. He passed his urine unconsciously. He expired after a violent convulsion.

The inspection revealed the following appearances:—On removing the calvarium, the dura mater presented nothing abnormal, but when this was removed a considerable chronic arachnitis was presented. When removing the brain, and about to divide the optic nerves, the scalpel struck against the metallic point of a substance directed obliquely upwards and backwards, and protruding into the cavity of the skull, close to the sella turcica.

The foreign body, which was at once seen to be the cause of death, was recognized as the brass ferrule of a small walking cane. On probing the nostril a foreign substance was touched, which proved to be the broken end of the cane, the point of which was previously seen.

It was evident that while fencing, the cane had accidentally struck the unfortunate man's face, and becoming impacted in the sphenoid bone, had broken off short. It would have been almost impossible to have extracted it during life, even if it had been detected, from the force with which it had been wedged in the bone.—*Dublin Quarterly Journal*, May.

Dislocation of the Femur directly Backwards.

Dr. Horner relates an instance of this rare dislocation. A man, aged 35, whilst assisting to push a line of coal cars, was jammed, with a companion, between two of them. As well as he can recollect, he was struck on the buttock, and jammed against the front car. His companion was killed, the patient owing his life to the death of his fellow-labourer. The terrible contusion, swelling, &c., which continued for three weeks after the accident, prevented anything like an accurate diagnosis, though a fracture of the neck of the femur was suspected. At the end of five weeks, as he suffered much pain in the hip and down the limb, and was unable to bear his weight on the leg, a further and more minute examination by Dr. Horner detected a dislocation of the head of the femur upon the ischium, between the spine and the tuberosity. The signs were as follows:—1st, increased width and flatness of this buttock; 2nd, a hard round tumour (head of bone) beneath the gluteus magnus muscle, or rather about the junction of the gluteus medius and maximus; 3rd, very slight shortening, the heel not touching the ground when the pelvis was held firmly; 4th, foot apparently natural when in bed; 5th, when standing erect toes can be turned to metatarso-phalangeal articulation of opposite foot, and no further; 6th, toes can be turned out about thirty degrees, and no more; 7th, abduction of femur imperfect; 8th, abduction nearly perfect, as also flexion and extension.

Summary of the symptoms.—Perception of head of femur and its motion, on motion of limb; very slight change in the length of the limb; very slight variation of line of toes, but impossibility of fully inverting, and especially everting the foot. Two days after the use of pullies, as before detailed, eversion of the foot possible to 90 degrees; inversion perfect; improved rotundity of buttock; reappearance of the hollow of the buttock, just above the trochanter major; abduction of the thigh easy, and the patient fully sensible of a change in the state of the part, as well as of more freedom in his motions.

Treatment of Obstinate Ulcers by the Electric Moxa.—By Bransby Cooper, Esq.

A case of obstinate ulceration over the ancle, the size of the palm of the hand, had resisted all treatment, until the author tried the electric moxa, when it rapidly healed. On this case Mr. Cooper remarked as follows on the history of the invention and its application:—The employment of the electric influence for the cure of indolent sores was first introduced into England by an American physician, Dr. Hull. He had previously observed its beneficial effects in such cases; and some years ago suggested its application in a case of a large indolent sore on the leg of a patient who was under my care in Stephen Ward. This sore had existed for some time, and had resisted all ordinary treatment; it was submitted to electric influence by connexion with the poles of a small galvanic battery placed by the bed-side of the patient. In a very short space of time there was a most decided and marked improvement; but, owing to a little misunderstanding on the subject, which occurred with others officially connected with the institution, the treatment was abandoned, and the patient some time afterwards discharged, unrelieved, from the hospital. I venture to assume, however, from later experience, that had it been persisted in, an opposite result would have occurred, and the patient have been cured of his malady. The application of the electric influence, by means of a galvanic battery, was however so inconvenient that, as a therapeutic agent, it would, probably, have sunk into oblivion, had not the invention of the electric moxa, by Dr. Golding Bird, rendered its employment ready and accessible for ordinary uses. There is no complicated apparatus required; no obstacle, no impediment to its application in the hands of the general practitioner. All that is necessary is a piece of zinc and silver foil, each about the size of a crown piece, which, connected together with a few inches of copper wire, forms the metallic portion of the battery, which is completed by the intervention of the living tissues.

A blistered surface being made a short distance from the sore, the zinc plate placed on this, and the silver plate on the sore itself, a simple galvanic battery is at once formed, and a circuit of electricity established, passing in a direction from the zinc or generating plate by molecular decomposition through the fluids of the tissue to the silver or conducting plate, and thence reconducted to the zinc whence it originated, by (according to the modern doctrine) a polar arrangement of the constituent molecules of the copper wire, thus completing the circle. The battery is excited by the

chloride of sodium contained in the animal fluids, the chlorine being set free at the zinc plate, combines with this metal, forming chloride of zinc, which, acting as an escharotic, gives rise to the eschar that is produced; whilst the sodium, being liberated at the silver plate, to which it gives up its positive influence, immediately decomposes water, combines with its oxygen, and sets free hydrogen. It is not absolutely requisite to denude the dermis by means of a blister previous to the application of the moxa; for if the cuticle be moistened with a solution of chloride of sodium or common salt, when the zinc plate is to be applied, a galvanic current is established, and chloride of zinc formed, which soon destroys the cuticle, and produces an eschar of the adjacent parts, if its application be persisted in.—*Medical Times*, May 24.

MIDWIFERY.

Anomalous case of Pregnancy; Absence of the Fœtus. By Thomas Churchill, M.R.C.S., &c.

A woman, the mother of five children, became pregnant in the beginning of June. In September was attacked with slight hæmorrhage, which she attributed to a fright. During December and January, 1831, she had a repetition of the flooding, and a still more severe one on the 6th of February, upon which the author was summoned. On examination the os was found undilated, and by proper treatment the bleeding was checked until the 7th, when it returned, accompanied by labour-pains. The os was now dilated, and placental presentation was ascertained. The membranes were ruptured, and eventually the contents of the uterus were expelled, but to the author's astonishment there was no fœtus, nor even cord attached to the placenta. On careful examination of the latter, it appeared to be of full size, and perfectly formed. The fœtal surface was level, and in place of a funis, the vessels terminated in a round knob. The woman recovered.—*Medical Times*, May 17.

[Is it not probable that the fœtus escaped in one of the earlier attacks of flooding?—Ed. P. J.]

On Laceration of the Cervix Uteri and Perineum during Labour.—By Professor Simpson.

At the Edinburgh Obstetrical Society, Dr. Simpson read a paper on the above subject, of which the following is a summary:—

1st. Fissuring and laceration of the cervix uteri and perineum are not, as is generally conceived, rare lesions during labour; on the contrary, they are very common occurrences, especially in primiparous labours.

2nd. These lesions are not, as has been often alleged, necessarily the result of mismanagement, but they occur constantly in practic, despite every modification of management, and in cases also in which no kind of management has been adopted.

3rd. Evidence of the great frequency of laceration of the anterior structures of the perineum is furnished by,—1, almost every careful autopsy of women after delivery, whether assisted or not assisted during their labour; 2, by the contracted or shortened state in which the perineum is almost always found, when vaginal examinations are made for uterine disease in women who have borne a family; and, 3, by the fissuring or laceration itself being usually traceable, (under careful tactile examination), particularly in first labours, when that examination is instituted in the interval of pain, immediately before the passage of the child's head, or after its birth.

4th. Lacerations of the perineum may be often felt beginning in the form of slight roughish rents or fissures upon the mucous surface of the perineum, and these may extend either backwards or forwards; and if they extend forwards, they at last run over the edge of the perineum, and along its cutaneous surface, the mucous and cutaneous structures of the perineum being thus sometimes lacerated, whilst its middle, cellular, and fascial tissues are comparatively entire, or at least not so deeply and extensively injured,

5th. The proper management and support of the perineum, no doubt, modifies and diminishes this form of perineal lesion, but it fails far more frequently than is generally supposed, in entirely preventing it.

6th. The evidence of the frequency of fissuring of the os and lower or vaginal portion of the cervix uteri is the same in character, and consists principally—1, in the frequency with which slight laceration of the edges of the os, and of the mucous and middle coat of the cervix, is detected in autopsies after natural labours, and particularly with first children; and, 2, in the permanent marks of its previous occurrence, as exhibited in those cicatrices and irregularities of the cervix uteri, which anatomists have long empirically, but correctly, laid down as proofs that they, in whose bodies they are found, have been previously mothers.

7th. Fissures and lacerations of the vaginal portion of the cervix uteri not unfrequently occur to a very considerable extent in cases in which the tissues of the cervix have been rendered rigid by previous inflammation, by carcinoma, or by other morbid causes; and in such cases this fissuring or laceration, if limited to the lower or vaginal portion of the cervix, seems to be accompanied with little or no danger.—*Edinburgh Monthly Journal*, May.

Correspondence.

THE BENEVOLENT FUND.

To the Editor of the Provincial Medical and Surgical Journal.

Mr. Editor,—Will you allow me a small corner of your valuable journal for inviting the attention of your readers once more to the above Fund?

When your next publication appears we shall be within five days of the close of our financial year. Allow me to avail myself of this fact to urge upon all those who have not yet paid their subscriptions to do so immediately; and to impress upon those of your readers who are not yet subscribers, the importance of

no longer neglecting this great duty, and of enrolling their names, while yet there is time, in this noble work of charity and piety.

Established as the Benevolent Fund has now been for sixteen years, it is yet a melancholy fact that it is not adequately supported by the profession; and that the only *purely charitable medical fund* in England languishes for want of revenue. I am willing to believe that this is only to be accounted for by the fact that the supplication of the widow, the piteous lament of the orphan, the cry for help of the destitute, the naked, the starving, does not break upon the ear and awaken the sympathies of home and kindred. But the great fact of irremediable distres is *not less a fact;* and to succour those who are ready to perish *is not less a duty* because we do not see and hear them.

The attention of the profession has been greatly distracted during the past year by the claims of the "British Medical Fund," which by constant advertisement;—by the praiseworthy labours of its travelling secretary and advocate;—by frequent meetings in the provinces;—and by notices in the journals respecting these meetings, has been kept constantly and favourably before the public; while the quiet and difficult—unobtrusive and inexpensive labours of the Benevolent Fund have not met with that frequent and that public advocacy which its pretensions merit.

You will, I am sure, pardon me, Mr. Editor, for reminding you that the Benevolent Fund forms an integral portion of the Provincial Medical and Surgical Association; and that as such it has claims upon yourself as Editor, upon your journal, and upon every member of the Association which no other Society can have. Also, the Benevolent Fund has existed *sixteen years;* and, therefore, has the advantage of sixteen years' experience and successful working, while the British Medical Fund is only in the course of formation; and fifteen years hence *may or may not* possess equal claims upon the attention of the public; but that at present the adult efforts of the Benevolent Fund ought not to be crippled in favour of a new aspirant to professional patronage.

Forgive me, Mr. Editor, for pointing out to you that the claims of the two Funds are essentially distinct. Ours is a purely charitable fund; while the British Medical Fund is essentially a *provident institution;* and that its relief is *confined* to those *who are members;* in this respect being of precisely the same nature with many local, or district, or county provident funds,—admirably deserving encouragement, but never to be supported at the expense of that far higher and more needed institution, the Benevolent Fund. Allow me again to remind you that the Benevolent Fund is *the only purely charitable* medical fund in England; the only one which can relieve the great mass of professional misery now existing—a mass of misery unrelieved and unrelievable by all the *provident institutions* of the kingdom. This fact is practically confessed by all these institutions; for they constantly send us cases which they *cannot relieve,* because the parties seeking aid *are not members.*

Finally, Mr. Editor, let me entreat your influence, as already a subscriber, and the powerful support of your journal, in inviting each member of the Association to allow the gentler motives of charity and religion to move his heart in the right direction towards his pocket; and to urge that each one should resolve at once, ere the year closes, to administer to the relief of "the hungry," "the thirsty," "the stranger," "the naked," "the sick and in prison;" upon whose conduct it has been pronounced in the words of unerring wisdom, "Verily, I say unto you, inasmuch as ye did it unto one of the least of these my brethren ye did it unto *me,*"—unto that Saviour, in whom we all hope to find mercy, and in whose sacred name I make this very benevolent appeal, remaining, with much esteem,

Yours truly,

WILLIAM NEWNHAM,

Treasurer, and a subscriber to the British Medical Fund.

Farnham, June 18, 1851.

THE SEXAGENARIAN.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—I cannot "condole," with you on your obligation to publish "Sexagenarian" or any other "thoughts:" your discretion and independence have been tested on many recent occasions, and the majority of our members are too well satisfied with your Editorial tact to entertain any fear that you may peril their literary honour, or shed their ink unnecessarily.

The truth is, our *Journal* is not and cannot be what many other medical journals are—a periodical net to catch the crude extravagancies of medical Sciolists. We set out from altogether an opposite point, with an earnest desire to hear each other's opinions on political as well as practical matters, and have established our *Journal* as the readiest means of accomplishing this end. The Sexagenarian is entitled to a fair hearing with the rest; and let our Associates be assured, there is much entertainment in store for them if they only bring a happy temper to the perusal of the writings of the *αυτοβοηθος.* There is a religious sect in England, which enjoins on its members a confessional exercise, called "telling the experience," and it may be that the Sexagenarian is of this persuasion, for the biographical portion of the "thoughts" is poured out with the earnestness of an overburdened conscience, with the agony of one who who is impelled by a stern necessity to speak or die. The passages which relate to the early struggles are given with painful force, and remind one of Coleridge's Ancient Mariner; for surely our Sexagenarian hath "strange power of speech," and from his late exposition we think that in reference to the fearful scenes of his youth he might exclaim with that venerable sailor—

> "Since then at an uncertain hour,
> That agony returns:
> And 'till my ghastly tale is told,
> This heart within me burns."

On one subject, however, it was much to be desired that the Sexagenarian should have extended his remarks—I mean on quackery. He has given us a graphic description of hydropathy and homœopathy, but the great blot on our page he has left untouched.

Mesmerism has not come under the lash of the Sexagenarian, and it is difficult to account for this omission, unless, indeed, "the European reputation," as distinct from "the British," is at the bottom of it. The doctrines of Mesmer have found favour in the eyes of many of our Continental neighbours, whilst in England the profession has been shy in receiving their claims; it would therefore, perhaps, be an ungraceful act in one holding a commission in the service of a foreign power, to question in an unfriendly spirit the truth of a system which is specially protected in the land of his adoption, and hence, probably, the silence of the Sexagenarian on mesmerism.

One word more. It is evident, from the notice which has already been taken of the "communication of the Sexagenarian," that he is regarded by the Association as a gentleman of no ordinary pretensions. Less virtues and less faults had escaped criticism. How grievous, then, that the solid and genuine structure of sound sense should be obscured by such a wholesale plastering of mawkish egotism! Every disguise is a violation of truth, and however pardonable or justifiable it may be to put on the mask in our insignificant acts, which lose naught of their effect through partial concealment, for merely to conceal is not wrong; yet when higher principles are involved, and we have to penetrate through a thick screen of vanity to reach the good gifts of nature below, the effect is to cast a suspicion on the reality of the gift itself. "There are some faults slight in the sight of love, some errors slight in the estimate of wisdom, but truth forgives no insult, and endures no stain."*

I am, Sir,
Your obedient servant,
QUADRAGENARIUS.

June 13, 1851.

Medical Intelligence.

APPOINTMENT.

Dr. Crowdy has been elected Physician in Ordinary to the Brighton Dispensary, and Mr. Thomas Fuller, House-Surgeon, in the room of Mr. King, resigned.

NAVAL.—Assistant-Surgeon Alexander Robinson (1814) additional, of the *Victory*, flagship at Portsmouth, for service of a naval hospital, to the Portsmouth division of Royal Marines; James D. Cronin (1850) additional, of the *Victory*, to be borne on the books of that vessel for service in a naval hospital; and Robert P. R. Sparrow to the *Victory*.

MILITARY.—2nd Foot: Assistant-Surgeon Henry Clinton Foss, from the 55th Foot, to be surgeon, vice George Roche Smith, placed on half-pay. 55th Foot: Assistant-Surgeon Alfred Crocker, from the staff, to be Assistant-Surgeon, vice Foss, promoted in the 2nd Foot. Rifle Brigade: Assistant-Surgeon Francis Reynolds, from the staff, to be Assistant-Surgeon, vice Robinson, who resigns. Hospital Staff: Acting Assistant-Surgeon Francis Walters Knox to be Assistant-Surgeon to the Forces, vice Reynolds, appointed to the Rifle Brigade. Acting Assistant-Surgeon John Wyatt to be Assistant-Surgeon to the Forces, vice Crocker, appointed to the 55th Foot.

* Ruskin—Seven Lamps of Architecture, p. 27.

EPIDEMIOLOGICAL SOCIETY.

The address of the offices of this Society is as follows:—The Hon. Secretaries of the Epidemiological Society, 38, Berners Street, London.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Friday, the 6th inst.:—Frederick Cock, Appledore, Kent; Henry May Davies, Hastings, Sussex; Charles West Roberts, Bristol; Alfred Wall, Stratford-on-Avon, Warwickshire.

The following gentlemen were also admitted members on Friday, the 13th inst.:—Charles Cooper, Dublin; Isaac Lionel Crawcour, London; Henry Duncalfe, West Bromwich, Staffordshire; John Baker Freeland, Antigua, West Indies; John Hemming, London; Joseph Henderson, Alfreton, Derbyshire; Thomas John Kelly, Dundalk, County Louth; Sydney S. Lynch, London; Charles Osborn, Bognor, Sussex; Joseph Stead, Manchester.

SOCIETY OF APOTHECARIES.

Gentlemen admitted on Thursday, the 5th instant:—Charles Arettingham, Finchley Road; Horatio Wm. Costerton, Great Yarmouth; Stephen Orson Lane, Braincton, Devon; Horatio George Anthony Wright, Stockwell; John Freeman Wright, London.

Gentlemen admitted on Thursday, the 12th inst.:—James Stacey Hichens, Redruth, Cornwall; Richard Clark Perkin.

UNIVERSITY OF ST. ANDREW'S.

List of gentlemen who had the degree of Doctor of Medicine conferred upon them, May 9, 1851:—Henry Allen Aldred, M.R.C.S., London; Charles Alexander Bisset, M.R.C.S., Peckham, Surrey; John Le Gay Brereton, M.R.C.S., Ed., Yorkshire; Charles Gage Brown, M.R.C.S., and L.A.C., Middlesex; Edward Somerset Cleveland, M.R.C.S., Madras; Cydwelyn, Ellis, M.R.C.S., and L.A.C., London; Samuel Turner Fearon, M.R.C.S., Slanstead Herts; James G. Gaff, M.R.C.S., Ed., Newmonkland, Lanarkshire; Robert Douglas Hale, M.R.C.S., and L.A.C., Norwich; Constantine Holman, M.R.C.S., Hurstpierpoint, Sussex; Henry Hooper, M.R.C.S., London; William Jackson, Montserrat, West Indies; John Joseph Ledsam, M.R.C.S., and L.A.C., Warwickshire; Peter Leonard, M.R.C.S., Ed., Forfar; John Glover Loy Merryweather, M.R.C.S., Ed., Yorkshire; Thomas L. Nash, M.R.C.S., Dublin; Lewis Newnham, L.A.C., Sussex; Robert Parker, Lic. Fac. Phys. and Surg. Glasgow, Lanark; John Burchell Peren, M.R.C.S., and L.A.C., Somersetshire; Thomas Peete, M.R.C.S., Ed., Margate, Kent; Samuel Reynolds, M.R.C.S., and L.A.C., London; Frederic Joseph Rowen, M.R.C.S., Tipperary;

Craufurd Smith, Lic. Fac. Phy. and Surgeons, Glasgow, Ayrshire; James Spark, L.A.C., Newcastle-under-Lyne, Staffordshire; Thos. Richd. Heywood Thomson, M.R.C.S., Isle of Man; Benjamin Webster, M.R.C.S., and L.A.C., Yorkshire; Edmund Sparshall, Willett, M.R.C.S., Norfolk.

OBITURAY.

On the 6th inst., at his residence, Great Stanmore, Wm. Rogers, Esq., M.R.C.S., aged 54.

On the 8th int., at Amisten Place, Edinburgh, Dr. R. A. Miller, F.R.C.S.E.

On the 13th inst., in Brunswick Square, in the 91st year of his age, Thomas Phillips, Esq., late Member of the Medical Board of Bengal.

June 11th, in his 63rd year, Dr. Holbrooke, of Andover House, Cheltenham. The deceased was a member of the Provincial Medical and Surgical Association.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

LANCASHIRE AND CHESHIRE BRANCH.

The Fifteenth Annual Meeting of this Branch will be held at the Town Hall, King Street, Manchester, on Wednesday the 25th June, inst. The chair will be taken at 12 o'clock precisely, by Thomas Turner, Esq., of Manchester, President for the year. Dinner will be provided at the Albion Hotel, (opposite the Royal Infirmary), at *three o'clock*, for those members or friends who signify to the Secretary, on or before the 23rd inst., their intention of being present.

JOHN HATTON, Secretary.

114, Oxford Street, Manchester.

SUFFOLK BRANCH.

The Anniversary Meeting of the Suffolk Branch of the Association, will be holden at the Town Hall, Framlingham, on Friday, the 27th of June.

Members of the Council will meet at the residence of the President elect, Wm. Jeafferson, Esq., at one o'clock, and the Chair at the General Meeting will be taken at two o'clock, precisely.

The members and their friends will dine together at the Crown Hotel, at five o'clock.

Short papers, or briefly detailed cases of practical value will be desirable; members unable to attend are respectfully informed that any communication they may wish brought before the meeting will be taken care of by the Secretary.

It will facilitate arrangements, if members would be kind enough to intimate to the President-Elect, Mr. Jeafferson, or myself, whether it is their intention to be present at the Dinner or not.

CHARLES ROBERT BREE,
Hon. Sec.

Stowmarket, June 9th, 1851.

P.S.—Members who have not paid their Subscriptions, and who are not likely to attend the Meeting, are requested to send them to me, by post-office order.

It is desirable that subscriptions should be paid before the 30th of June.

BATH AND BRISTOL BRANCH.

The Bath and Bristol District Branch will hold its annual meeting on Thursday, June 26th, at half-past two o'clock, at the Bristol Medical Library, Orchard Street, Bristol, under the Presidency of J. A. Symonds, M.D. The dinner will take place at the Bath Hotel, Clifton, at six o'clock.

JOHN COLTHURST,
Hon. Sec., Bristol District.

YORKSHIRE BRANCH.

The annual meeting of this Branch will be held at the Medical School, Surrey Street, Sheffield, on Thursday, July 3rd, under the Presidency of Ferguson Branson, M.D. The chair will be taken at one o'clock precisely. The members and visitors will dine together after the meeting.

W. D. HUSBAND,
Hon. Secretary and Treasurer.

York, June 19, 1851.

NOTICE TO MEMBERS.

The publishers having received information that there has been some irregularity in the transit of the *Journal* through the post, it is particularly requested that any gentleman not receiving it punctually will immediately communicate the same to the office of the Association. The *Journal* is published every alternate Tuesday, and despatched in time for the evening post or the Wednesday's day mail.

TO CORRESPONDENTS.

Communications have been received from Dr. Williams, Mr. Landor, Birmingham Pathological Society, Dr. Radford, Mr. Hardy, C——r, and Mr. Sands Cox.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

[Reported by MR. HENRY GREEN, Student.]

LECTURE VII.

On Cardiac Inflammation, &c.

Gentlemen,—We now come to consider the important subject of cardiac inflammation. This may occur either in the muscular body of the heart, or in its fibro-serous linings; the former, however, is so very rare an occurrence that I cannot dwell upon it with any practical advantage. Certainly, if the mollification that takes place in scurvy or typhus fever, and other diseases, in which the blood is in a liquefied condition, were to be reckoned as a consequence of inflammatory action, then carditis would be by no means an uncommon event; this, however, is more than doubtful. This mollified condition has been remarked, from before the days of Dr. Matthew Baillie, who further observes, as a singular matter, that the softening should be chiefly apparent in the thick walls of the left ventricle; and that, quoting Portal, it "can neither be compared to the effect of gangrene, nor to a suppurative process." Taking into consideration the many additional observations that have since been made, it appears pretty clear that it is mainly owing to the fluidity of the blood in these diseases, and not to any strictly inflammatory action; and this being accepted as fact, it follows, as a necessary consequence, and in explanation of the softening being most manifest in the left ventricle, that that part must be mollified in the highest degree which happens to be most developed, and to contain the greatest proportion of morbid blood. In such a case, although there be no proper rupture of a blood-vessel, or of the walls of the heart, blood may yet be found intermixed with the pericardial serum. This appears to ooze from the walls in the same manner as it would ooze from a congested and relaxed kidney, or from the surface of the intestines or lungs. I lately witnessed this state of things in the body of a patient who died in our hospital, I think from apoplexy, consequent on long drunkenness. The pericardial serum was quite red with blood globules. There was no rupture of any proper vessel, but, on pressing the heart, small drops of thin blood were seen trickling over its surface, the muscular fibre being in a fatty and softened condition, but certainly with no appearance of inflammation in its common acceptation. But, when pus is found in the muscular tissue of the heart, there can, of course, be no doubt of a previous inflammation, and, rare as this is, it has been most decidedly recorded by certain high authorities, and there is no abstract reason why it should not take place. Andral has spoken of a case in which he found the muscular fibres infiltrated with pus. Dr. Latham, in cutting through a heart, found pus oozing from numerous pores over the whole minute structure. And Dr. Graves has also recorded an abscess which was found at the apex, under the floor of the left ventricle, and which contained about two ounces of proper pus. In the latter case the principal symptoms referable to the abscess, were palpitation, cough, and agonizing pain at the organ itself. There were hypertrophy with dilatation, and valvular disease besides, but I think that the pain and palpitation would have been the most marked symptoms, supposing nought else had existed. The treatment would be, by blood-letting, mercury, and antimony, if discovered in time, but under any circumstances, the slightest symptom of inflammatory action in any texture of the heart is to be boldly and decidedly combatted.

On the other hand pericarditis is no uncommon disease; it may arise idiopathically, from causes altogether unknown, but that is a rare occurrence. More commonly it is traceable to an inflammation extending from other parts in the neighbourhood, such as the pleura or lungs, (as in the girl Bates,) or from the pressure of a tumour, (as in Faulkner,) or from suddenly suppressed cutaneous exhalations, as in the numerous cases of idiopathic pericarditis from cold, but most usually it proceeds from a specific determination of rheumatic salts to the sero-fibrous textures of the organ. This is so frequent an occurrence in rheumatism, that the heart must always be examined while treating that disease. The chief danger, indeed, is to be apprehended from this organ, or the brain, becoming involved; and it is often from neglecting to attend to the cardiac complication under rheumatism, that the foundation of those organic changes is laid, which ultimately lead to all those secondary and tertiary consequences in after life, which, while they burden and oppress, and greatly shorten existence, yet only extinguish it by slow and painful degrees. If the pericardial inflammation be slight, there may only be observable a somewhat unwonted palpitation, or a merely quickened pulse, and a slight sense of uneasiness, or none at all; but if it be more extensive or severe, great anxiety will be present, as well as palpitation and frequent pulse. The patient will be able to refer his pain directly to the part affected, darting sometimes to the left shoulder or lower part of the left scapula, and down the left arm; and he will not be able to lie upon his left side, or upon either the right or left. The face will be pale; the respirations hurried; the alæ nasi expanded; the brow and eyes will express much uneasiness; and the sufferer will start suddenly in sleep, as from a painful dream; at the same time a faint dry friction-sound may, perhaps, be heard on auscultation, but without any increased dulness on percussion. This is the first stage, and, if not checked, it may next run on to effusion of fibrinous serum or lymph, which may afterwards either be absorbed as such, or degenerate into pus, or form permanent adhesions. In milder forms, this latter exudation may only

appear in slight proportion, rendering the serum milky white, as in the case of Faulkner and others; but in more severe inflammations, the heart may be bathed in a vast quantity of pure pus, say twelve ounces or more, which shall fill the whole pericardium. This I witnessed in the body of a lad in the Edinburgh Royal Infirmary, under the care of Dr. Christison, in whom the existence of such a condition was quite masked, partly by a contemporaneous pleurisy, accompanied with much effusion, and partly because, from the pressure of the pus, the motions and sounds of the heart were, as it were, buried. As these changes proceed, the physical signs will become altered according to circumstances. Thus, if the dry state of the lining membranes, as indicated by the faint friction-sound, and which is the first physical result of inflammation, be followed by a simple increase of the serous exudation, so as to fill the pericardium and press upon the heart, then there will be an extended dulness under percussion, while the sounds and motions of the organ will be obscured. But if fibrinous lymph be thrown out, and proceed to coagulate, and to deposit itself as a rough coat over the surface of the heart and pericardium, then the friction sounds will return with still a rougher and rougher note. Or if, after being worked up in this way for some time, it should form itself into tough plastic bands, uniting the heart and its bag, so as to be stretched out and twisted about at every successive contraction, then the sounds may resemble those of a file or saw, or creaking leather. The progress of these symptoms was well exemplified in the case of the little boy Bonny, aged 11. First, after a neglected attack of rheumatism, we had the to and fro friction-sounds, with vehement action of the heart. Next, we had an obscure and oppressed fluttering, as if the organ were pressed upon by fluids. Lastly, the friction-sounds returned, and were accompanied, at length, with creaking and chirping noises at the base of the heart. At this stage he left the hospital, as he longed very much to be at home with his mother; he was then still pale and thin, with some evidences of pulmonary tubercle, nevertheless, his appetite had improved, and his pulse fallen to 84. If the formations be so thick, strong, and inelastic, however, as to bind the heart down, the organ will assume a jogging, clogged, and irregular motion, as in the case of Bevan, spoken of in the former lecture; and, if they become resolved into thick pus, there will, as already observed, be extensive dulness, with a very marked obscuration both of motions and sounds, while dyspnœa is extreme, and the pulse is faint and small, and the face deadly pale. Such are the usual symptoms of pericarditis when it runs through all its stages. Nevertheless, we are to regard with strong suspicion any ascent of the pulse to 120, (as the earliest sign,) provided such ascent be not traceable to any local or general affection which shall account for it as a secondary result. In rheumatism, a pulse of much more than 100, should excite due attention to the heart.

Thus, by keeping steadfastly in your mind's eye the anatomical structure of the affected part, and the natural succession of pathological changes which are most likely to occur, you secure for yourselves a simplified mode of investigation, such as will prove available under any amount of complication, or even confusion of signs and symptoms. For, although there be certain occasions when many of the principal means of diagnosis are absent, and when the patient himself feels inclined to refer his sufferings to other organs, such as the lungs, or brain, rather than to the heart, which might seem, therefore, to be unaffected; yet I cannot admit that any distinct invasion of pericarditis, if examined through all its stages, could, under our present improvements, escape detection at one point or other of its progress. In such an instance of extensive pleurisy as the one in the Edinburgh Infirmary, already cited, doubtless there would be many difficulties surrounding its discovery, yet even there, I think we may fairly conclude, that if the sounds of the heart should be daily listened to from the beginning, while the patient held his breath, some evidences would be afforded of the existence of pericarditis before it could proceed to the extremity of creating such a store of pus. I do not say this with any view of reflecting upon its occasional non-recognition by eminent men; for a practical physician, who has to administer within a given period to numerous patients, cannot be expected to lose time in searching for minute complications, which, even if they were found to exist, would not materially alter the course of treatment; but I state it only as the expression of my conviction that practitioners of such skill would find little difficulty in discovering the pericarditis, if it were of any special importance in qualifying the management of the other disease. You will find, on perusing books and reports of certain cases, that many difficulties are stated as lying in your path, and numerous exceptions and deviations from common rules are mentioned as of frequent occurrence. You will find the same in actual practice. But it is no part of my duty to deter the clinical student from pursuing his studies, by arraying before him those negative evidences which he must encounter. I have laid down for you such positive and usual signs and symptoms as will most likely accompany certain positive and usual pathological stages. Follow these diligently and rationally, and you may rely upon it that you will find quite a sufficiency of difficulties and exceptional negations in your courses of practical study to teach you caution and reservation in any diagnosis, without that fore-knowledge, or rather fear of them, which is too apt to beget in the beginner the indifference and indolence of desperation. Throw aside, therefore, any discouragements which you have already received, and gird yourselves up for self-exertion. If all the actual difficulties which men were appointed to meet with in their expeditions were piled up before them on their first day's march, the race of heroes might be at an end. But while, with some reasonable caution, hope is inflamed for the adventure, such difficulties will be spread over a series of times, and so will be subdued by perseverance and experience. Let it thus be with you. Attempt, with all energy, to recognize clearly the positive evidences of healthy and morbid action, without

distracting your mind by any mere possibilities, founded on negations, and obscurities. Be ready, at the same time, to receive with caution and candour such explanations of negations and obscurities as higher experience may be able to offer, and you will certainly fulfil all those ends which I have in view, in adopting the plan of symthesis and simplification in clinical affairs.

Before proceeding to speak of the treatment of pericarditis, I shall first discuss another local inflammation with which it is generally connected in a greater or lesser degree; that is, endocarditis. Endocarditis may arise from precisely the same causes as pericarditis, and, like it, is most commonly dependent on rheumatism. It will give rise to an increased excitability of the organ; and, therefore, either palpitation or a permanently exalted pulse will be pretty sure to accompany it, though not much sensible pain. It may, like other inflammation, throw out serum, or fibrinous lymph, or pus. The former, however, is not likely to be discovered in such a situation; while, as to the latter, I am not aware that it has ever, to any amount, taken place, as most probably there would be a fatal termination before it could reach that point of action. Fibrinous lymph, therefore, is the ordinary exudation recognised in that situation, which may either be thrown outside so as to form clots or polypi, or what are called vegetations, within the cavity, or be so deposited upon or beneath the surface as to produce a very sensible thickening of the tissue. This, of necessity, will give rise to certain morbid sounds from the heart, more especially if the inflammation and its effects have fixed upon the coverings of the valves or of the root of the aorta, in which case there may be a blowing or still rougher murmur, either double or single, at each contraction of the organ. From the more stimulating quality of the arterial blood this affection has been found to seize upon the left side of the heart in preference to the right; and, therefore, the sounds are to be looked for over the aortic and mitral valves. As this morbid condition is often combined, as I have said, with marked symptoms of pericarditis, it may frequently be treated so actively as to ensure a resolution of the action and a reabsorption of the morbid deposits. But it has also often been neglected under rheumatism, and the consequence has been that chronic inflammation has continued for some time after, confirming the solidity of the deposits, and so transforming the fine elastic texture of the valves, &c., that they have become unfit for their proper office, and led to all the ordinary consequences of obstruction on the one hand, and patency on the other; that is to say, hypertrophy and dilatation, followed by venous congestion and general dropsy. Thus the plastic exudations may simply thicken and harden the valves, or the roots of the chordæ tendineæ; or they may be the means of effecting adhesions between these parts and the opposite walls of the organ; or they may form wart-like excrescences and prolongations that shall still more seriously impede the proper functions of the valves, causing them, it may be, both to offer obstruction to the passage of the blood forward and facilities to regurgitation. A further stage may lead to still further changes, by the induction of a degenerative action within these accidental tissues, so that there may follow deposits of scrofulous or calcareous matter; but as these latter will be treated of under another head they need not be dwelt upon at present. I shall only further observe that such alterations of structure necessarily lead to the emission of those morbid sounds during the action of the heart of which we have already spoken while treating of the mechanism of the organ. According to the narrowness or wideness of the apertures, or the roughness of the surfaces, they will assume every degree of harshness, from the gentle blowing murmur of a slight impediment, or slight dilatation, to the rasping, sawing, or loud croaking sounds of more confirmed disease, as already illustrated to you by sundry cases. I cannot proceed to convey to you by mere words more accurate ideas of these matters than are to be found in the descriptions of actual cases; and I shall, therefore, leave you, by diligent practice and observation, to acquire the real knowledge for yourselves. Proceed from day to day in the exercise of percussion and auscultation, both in the healthy and diseased body, until you become expert in them. Do not expect to recognise the sounds at once for yourselves, but seek, time after time, to discover them under the guidance of experience; and after you have once heard them you will not forget them. It is the careless neglect of this subject during the period of pupilage, and the shame of acknowledging ignorance of it afterwards, that constitute the number of incredulous and inefficient, yet self-satisfied practitioners. All such affections, interfering so directly with the current of the circulation, must either lead directly to secondary disease, or give an immediate liability to it. There will generally be anxiety, disturbed sleep, habitually knitted brows, and prostration of energy. The breath will be short, and the person prone to suffer from dropsical swellings in different parts of the body. Though every portion of the frame, however, is liable to be involved, yet some parts will, as already explained, suffer sooner than others, according to the side of the heart that may be chiefly affected. Thus, when the defect occurs in the tricuspid valve (for the pulmonic valves are rarely involved) there will follow a tendency to venous congestion and serous effusions in the general system, while, besides the sounds heard over that valve, the regurgitation will be apparent to the eye within the jugular veins. From the insufficient supply to the lungs, these will also become affected; and, as the additional efforts made by the ventricle ultimately lead on to hypertrophy, the right side will become so augmented in bulk that the impulse will sometimes be felt to take place underneath and to the right of the sternum, unless any adhesions have already bound the heart upwards. These facts were well illustrated in the case of John Wragg, out-patient. He was a car proprietor, aged 45, and had been much exposed to night air, &c. About three years before, he first began to experience pain at the heart, with dyspnœa and slight dropsical swellings. He had been under some treatment; but all the symptoms went on steadily increasing. When he at length

sought the aid of the hospital he was burdened with hydro-thorax, ascites, and hydrocele, along with enormous anasarca of both upper and lower extremities, causing paralysis of the left arm. He had a *grasping* agonizing pain at the heart, over which there was a great bulging of the ribs, and the apex beat violently to the right of, and beneath, the sternum. The dulness was extensive; a loud murmur was heard over the tricuspid valve; the jugular pulses were very distinct, pulse at the wrist 100; respirations 45, and laboured; urine slightly albuminous. The diagnosis was hypertrophy and obstruction of the right chambers, as the causes of the general dropsy. He was seen once a week by myself, and was very frequently visited by my late clinical clerk, Mr. Metcalfe. The indications were to remove the dropsy and diminish the hypertrophy, if possible. To this end he began, on July 2nd, to take cream of tartar and jalap every morning, along with digitalis and other diuretics thrice a day, while local derivants were employed for the local affection. On the 15th the pulse was 80, respirations 30; the left leg and scrotum were natural, and the right leg was diminishing. He was cupped to eight ounces, and continued the medicines. On the 22nd the swellings were entirely gone, and respirations 26; the motions of the heart were less tumultuous, and he felt generally easy, though the dulness, &c., were as before. Some nights after this I was suddenly requested to attend. He had ventured to partake largely of red currants, and all the heart symptoms were greatly aggravated. The stomach and bowels, distended with wind, pressed against the diaphragm. His eyes stared and rolled about; he gasped for breath; his heart jogged in the most irregular manner; and so he died, in great agony. Contrary to our usual custom, no *post-mortem* inspection was made in this case; but, at the same time, the symptoms were so clearly developed that no one experienced in such matters could have one moment's doubt on the subject. If the morbid alteration, on the contrary, has taken place in the left side, in the aortic or mitral valves, or both, the fact will be indicated by the sounds emitted from these valves respectively. In any case there will be induced a certain feebleness of the systemic circulation, leading to languor and debility, along with such an obstruction to the return of pulmonic blood as will bring about congestion of the lungs, with shortness of breath, perhaps asthma, and all the other disagreeable consequences of an imperfect action in that principal organ. Single sounds will indicate in such a case obstruction alone, or regurgitation alone; but double sounds will indicate both the one and the other; and as a certain continuance of this condition induces hypertrophy of the left ventricle, there will occur a harsh strong impulse of the apex, and an extended dulness on percussion, unless other complications should interfere to prevent them. At first the advances of these changes may be so gradual that the patient will only discover by slow degrees that his respiration is becoming markedly different from that of other people, and that his loss of physical energy and liability to the thousand ailments consequent on general or pulmonic congestion, are not consistent with his time of life, previous vigour, and hardihood. Ultimately, however, if unattended to, the results are of the most appalling kind, and the victim sinks under such a complication of pains and penalties, as reconciles the dearest friends to his death, as a simple release from suffering. Thus the whole body may become oppressed with dropsical effusions; not merely deforming the limbs, and distending the abdomen, but also filling the chest and pressing with additional weight upon the already gorged lungs. In this state both the lungs and heart continue to make violent struggles for the protraction of life. The patient cannot lie, but sits up, and yet he cannot sit in one position but for a few minutes at a time. His tightening pains and suffocating feelings compel him to stretch hither and thither in search of the necessary element of air, without obtaining it. His mouth is wide open, his eyebrows drawn up, and the white of the eyes is seen like a ghastly circle round the black, and so struggling from day to day, he at length dies, exhausted. Such is the ordinary course of such valvular disease when neglected and left to make its progress, under the usual excitements and exertions of an active life, as in the fatal cases of Wragge, Anderson, and Faulkner. But yet it must be stated, that with a slight obstruction or regurgitation, life may be protracted in comparative ease for an indefinite period, provided it be combatted occasionally, as circumstances may require, and the patient be able to pass that quiet and even tenor of life that shall never excite the respiration or circulation. Yet, even this person, with all his moderation, ease, and calmness of existence, must still be liable to the usual "ills that flesh is heir to," and under any such visitation, however trifling to another individual, his central organic affection will always render his case precarious, especially if the attack be one involving his lungs, such as asthmatic or common bronchitis, or more especially influenza. Such patients, if they desire to protract life, must not only live quietly, but must obtain instant advice on the first onset of any other disorder, but especially such as involves the lungs. Nay, they ought never to wait until cough, or tightness, or rawness supervene, but take protective measures as soon as they find their respiration increased beyond its standard, by any such exertion as a short walk, or running up stairs. By this means existence, as I have said, may be lengthened to an indefinite period; but otherwise there is but one end for the disease. Thus, in the case of Elizabeth Wheeler, already recounted, with double first sound of the heart, asthmatic bronchitis, and extensive anasarca, she was cautioned when leaving the hospital relieved of the two latter complaints, that under any great exertion they would be sure to return, and so, having to labour for her subsistence, she did come back after a short time, with ascites. Of this she is again relieved, but her life must be a perpetual struggle against this perpetual threatening of the enemy.

The principles of treatment that must guide us, in all these cardiac inflammations, and their consequences, are the same, viz., direct abstraction of blood from the

loaded vessels, and counter-irritation, with the internal use of those medicines which are known to counteract inflammatory action and promote absorption, as well as those which subdue irritability, or neutralize the poisons which may happen to be the exciting cause. Thus, in the acute cardiac assaults which take place in rheumatism, &c., if the onset be exceedingly sudden and formidable, it may be necessary at once to draw blood boldly from the arm, and follow up that step with the liberal administration of opium and mercury, as well as colchicum, &c. But, more generally, if the threatening of the attack be foreseen, as it usually may be, by noticing the preceding simple palpitation, or merely frequent pulse, *i. e.*, more than 100 or 110, smaller amounts of blood, locally abstracted, may serve the same purpose. If necessary, it may be followed by a blister and belladonna plaster, while mercury and antimony are exhibited in conjunction with a small amount of opium. At the same time that these means are pursued, as if for simple cardiac inflammation, the specific poisons must be sought to be neutralized and expelled from the system by other means. First in the list stands colchicum. Act how it may, it is now certainly established that, through its instrumentality, the uric acid in the blood is changed into soluble urea; and we have demonstrated in this hospital that all the beneficial effects of colchicum may be produced without the induction of its purgative or other physiological effects. Neither, when judiciously used, is it found to act injuriously on the liver, or to produce any such depressing effects as are sometimes attributed to it, the pulse and heat of skin being merely lowered, not by its sedative virtues *per se*, but by its beneficial decomposition of the morbid salts, and consequent removal of the irritation and pain dependent upon their presence. It behoves you to study such subjects most profoundly. Physiology may be the soul, but pharmacology is the right hand, of physic. Coupled with the colchicum, draughts may also be administered at the same time, of some diuretic, such as scoparium, holding in solution soda or potash, though I rather prefer the latter; and as the blood is generally in a fibrinous condition, it may be well to conjoin the carbonate and nitrate of potassa together, the latter having a special power in breaking down the "crasis of the blood." Phosphate of soda is likewise used as a solvent of the uric acid, and magnesia is an admirable agent, when acidity is suspected in the lower bowels; but while these are given with chemical views, irritability or pain is also to be subdued by the use of hyoscyamus, aconite, digitalis, or conium. I almost invariably use the two former, though the digitalis is of greatest use when violent action of the heart is increasing the inflammation; and, on reference to the recorded practice of the hospital, you will see the precise doses, times, and modes in which these medicaments are administered, as in the cases of Ryley, Wortley, Phillips, Bull, Charlton, Newton, &c., for rheumatism is exceedingly common here. If the inflammation be chronic, or the morbid deposits have continued as permanent incumbrances, the treatment is still the same, though of a more mild and persevering kind in accordance with the chronic character of the ailment, and modified according to the constitution of the patient. Thus, small abstractions of blood, repeated from time to time, along with occasional little blisters of two inches in diameter, or a seton, if the habit be not too irritable, are the most advisable steps. Friction of mercury and iodine may be employed at the same time. If the heart be very irritable, and quick in its action, it is to be soothed by digitalis, as already observed. Should the patient be corpulent and ruddy, the abstraction of blood may be more free, and the diet very moderate; but if he be weakly and pale, such tonics as cinchona and iron will have to be employed, along with generous diet, in order that he may be able to bear, from time to time, the small local bleedings that may be necessary under dyspnœa and the other more pressing symptoms of cardiac inefficiency. In this manner, even though we may not succeed in curing the disease, we may prevent its increase, and arrest the whole train of the usual secondary consequences, as illustrated in the cases of Twells, Capel, Bevan, Harrison, and sundry others. The practice consists in a vigilant watching of the constitution over a series of months or years, or to the end of life. The valvular forms of the disease of which I speak are very common in this town, and you have had ample opportunities of studying them in the hospital. Their local frequency is obviously traceable to the great prevalence of rheumatism at an early period of life, the masses of the population being exposed to alternations of temperature from the nature of their occupations, and often sitting with one part of their body towards a scorching fire, while the other part is open to cold draughts from a door or window. They will also remove themselves very incautiously from a heated factory to the cold air. Under the rheumatic attacks which may follow in consequence of this suppression of the invisible exhalations, they too often either do nothing at all beyond rubbing in a few inert domestic oils, and taking purgatives, so allowing the disease to expend its natural force, and leave these organic results behind, or they obtain nostrums from the shops, or from empirics, quite irrespective of actual symptoms, or resort to other sources of cheap but equivocal treatment. I state such facts to you only as illustrating the natural history of the disease now under consideration. And you must often have remarked what a very great number of extremely young persons present themselves here, labouring, not only under common rheumatism, but under serious organic affections of the heart, as the little boy Bonny and the little girls Isabella Robinson, Jane Hopkins, &c., not one being above twelve years of age. It will therefore, behove you, in that line of general practice to which so many of you may be hereafter devoted here or elsewhere, to examine most carefully the condition of the heart whenever you find any exaltation of the pulse, especially if accompanied with rheumatic pains, or lithic deposits in the urine. If once inflammation be kindled in such a quarter, and proceed to effect organic changes, there can be no longer any security against the other consequences, which I have

just been enumerating. Sooner or later they will successively marshal themselves upon the line of morbid action, and proceed with dreadful regularity to the final issue. And when you witness, as you have with us so many opportunities of witnessing, those painful, protracted, and laborious struggles which characterize the later stages of such cardiac disease, you will surely be inspired by a generous and holy desire to avert the induction of those causes, which now so often lead to a miserably oppressed life and premature death.

LECTURE

ON THE

DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By Dr. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE III.

Objective Symptoms and Physical Examination of the Organs of the Chest.

Gentlemen,—In my last I said that the physical examination of the organs of the chest forms the most perfect, the most splendid part in children's practice. In fact, not only does a little child not give us those accounts and indications by which an adult patient frequently enlightens us as to the state of the lungs and heart, but it even not seldom happens that in little children very severe acute inflammations of the lungs and of the pleura take place without cough, or, at least, without appreciable cough. I can state this not only as a fact which I have frequently witnessed in my life, but also as a source of mistake at the same time. Little children affected with very acute pleurisy are sometimes impeded in coughing (during the first stage of this disease) by severe pain, and by the exhaustion consequent upon it. Again, if a large transudation fills up one half of the chest, suppressing all the activity of the corespondent lung, and the other lung is perfectly healthy, they do not cough under these circumstances; and as there is in this state much oppression of the brain, and even a degree of sopor, I have seen persons wrongly apply leeches to the head. Then, if the child survives to that height of the disease, the cough begins, and increases in proportion with the progress of the absorption of the liquid. It may be that there was in such cases some slight cough, but it was, at least, very indecisive, and perhaps escaped altogether the attention of the assistants. In those cases either percussion or auscultation would have assisted us, and been enough to make clear the quality of disease. There are likewise other cases, less serious, but in great number, in which by no other means than by physical examination can we get exact information. It would be, however, extravagant and disadvantageous should we neglect to observe the external phenomena of respiration, crying, and cough.

Before we apply our ear to the chest we observe closely the child with our eyes. The *respiration*, if deranged, will be either slow, deep and heavy, or quick, superficial, and checked. The slow and heavy inspiration is peculiar to some adynamic fevers, or cerebral transudations. The quick and frequent, if not also checked, is common to febrile excitement; but if superficial and checked, then it denotes either an affection of the respiratory organs, or of those of the circulation. This sort of respiration is dyspnœa, united with much anxiety and occasional sighs in affections of the heart, and with expression of pain in the countenance in severe pleurisies. We look then at the *movement of the chest*, which, in cases of impeded inspiration, will appear to move more or less incompletely, *i.e.*, in lobar pneumonia and pleurisy. In this case there will be abdominal respiration. Sometimes we perceive proportionally less movement on the affected half of the chest; this is even the case in very strong rheumatic pleurodynia.

Crying is impossible in acute pulmonary or pleuritic affections, just because the *outcry*, as a more violent act of expiration, makes necessary a deeper inspiration incompatible with those affections. If, then, under such circumstances, the child inclines or begins to cry, we see immediately that the *back-draught*,—that is, the inspiration, is checked, and thus the continuation of loud wheezing is prevented. Speaking in general of crying, if the child at once begins violently to weep, and then ceases, and shows good spirits, and we observe this change several times, we may suspect either a spasmodic pain in the abdomen, or otalgia. The most sudden and severe pains in children are,—spasm of the bladder, (dysuria spasmodica,) of the stomach or intestines, and otalgia. If the child cries in consequence of dysuria, we observe the urine voided drop by drop; if ceasing to weep, and eructations come out, we conclude there is spasm of the stomach, and if flatulencies are emitted, the cause of the previous violent spasm may be a spasm of the intestines. If, during most violent cries, the child inclines its head laterally, and brings one of his hands near one ear, we may suspect otalgic pains. I must acknowledge, however, that in some cases I did not observe those latter signs, and it was only afterwards that the commencement of mucous or purulent discharge from the ear made clear the cause of violent crying.

On all occasions when children weep *violently*, there is a disposition to some convulsive movements, or to spasm of the larynx. The first consist in short and repeated shocks of back-draughts, the latter in impeded, noisy, forcible, and prolonged back-draughts. If this happens occasionally in consequence of long and vehement crying, it is of no importance; but if those abnormal modifications of crying are frequent and vehement, it signifies a nervous disease. Thus, in

laryngeal spasm, after each short checked outcry, there ensues a prolonged, forcible, and noisy back-draught.

Frequent and prolonged weeping, with some uneasiness and irascibility, this latter persisting even during the intervals, is very seldom to be attributed merely to the temper, but most probably to some illness of the child.

Coughing is a more or less vehement and suddenly checked expiration, preceded by either a free and deep, or a superficial and impeded inspiration. Cough, in simple bronchitis, consists of loud and full expirations, with a free and deep inspiration. In pneumonia the expiratory act of cough is more or less superficial, imperfect, and the inspiration laborious or checked. In acute pleurisy these qualities of the acts of coughing are the most pronounced, and we observe during their performance an expression of pain or of anxiety in the child's countenance. If the cough is only occasional, short, but not checked, with persistent expression of painful anxiety on the face, yet with slow, deep, and long inspirations, this is the general character of cough connected with affections of the heart. Violent, loud, short, but frequently and rapidly following expiratory acts of coughing, with interposed, single, loud, long, and full inspirations, is the character of convulsive cough. Cough is, in general, more moist in children than in adults, moist even sometimes in the first stage of acute pneumonia. After we have observed for some time the respiration of the child, or the respiratory acts of its crying or coughing, and after we have observed these acts in different positions, (dorsal and both laterals, because in pneumonia the respiration is more easy, and cough less irritable, if the child lies on the affected side,) we proceed to the—

Inspection of the structure of the chest.—We distinguish the phthisical and the rachitic structure of the chest. The former, always united with a delicate slender complexion, appears to be round, but evidently narrow in its upper part. The rachitic chest is laterally compressed, or better to say excavated, whilst prominent at the sternum, and presenting the shape termed "pigeon-breast." In those latter cases we find also frequently an abnormal curvature at the spinal part of the chest. It is most important to be aware of the rachitic structure of the chest, because I found the phenomena of visible respiration, as well as those of auscultation and percussion, considerably modified by it. For some years I was in frequent embarrassment with the diagnosis of similar cases, till at least clinical observation, united with repeated dissections of similar children, led me to some conclusions. A high degree of rachitic compression impedes the respiratory acts. The ribs deviating from their normal curve, cannot obey the respiratory movements of the intercostal muscles. Thus we see in these subjects a high degree of dyspnœa; then passive congestion takes place in the lower half of the lungs, and mucus accumulates. Auscultating on these very parts we perceive little or nothing of the vesicular respiratory murmur, but frequently some fine râles, resembling the subcrepitation, whilst towards the upper half of the dorsal part of the chest we hear a violent bronchial respiration, resembling the tubular soufflé in pneumonia, with occasional large râles. The sound of percussion is something dull at the lower dorsal part, in particular near the spine, where the spongy part of the vertebræ is frequently in a state of swelling. The percussion is, anteriorly, in general clear, and very clear at the lateral hollow of the excavated parts of the chest. All these abnormal phenomena proceed from the structure of the chest. Chronic bronchitis and passive congestion, are most common in these subjects, but it is important to know, that acute pneumonia and lobar hepatisation, are quite strange to them. In some of these cases I discovered, by dissection, that state of passive carnification, at the back margins of the lobes, which Legendre and Bailey term the "fœtal state."

The *particularities and difficulties of auscultation* on little children are many:—

1st. The respiration of young children is regularly quick and noisy. This must be allowed for.

2nd. There is much propensity to mucous secretion, and as they do not eject it, mucus accumulates, and causes a great many large and fine râles, which veil the respiratory murmur, and impede us sometimes in perceiving the crepitation in pneumonia, or the rubbing sound (frottement) in pleurisy.

3rd. Mucous obstruction of a large part of the bronchial tubes sometimes takes place, and prevents the perception of the vesicular murmur. This case we enlighten by percussion, as the sound in mucous obstruction is clear, or but very slightly dull. Nor is there true bronchial respiration in these cases.

4th. A little child's chest is of a small extent, consequently if we auscultate, even at the middle of the chest, our ear is struck by the respiratory sounds of the trachea and of the large bronchial tubes, and there is difficulty in perceiving slighter alterations of the sounds.

5th. The child will neither perform a deep inspiration, which sometimes we need to observe, nor will it speak words at our wish and command; thus, bronchophony, pectoriloquy, and œgophony, are lost from us, we can only hear sometimes the modified sound of the voice during cries.

In order to get a full inspiration, as fall as the child can perform it, I find the best plan the following:—I order the child to be taken in the arms of its mother or nurse, in a position which allows auscultation, behind and laterally; then I approach cautiously from behind, and lay one of my hands on the upper part of the abdomen, and exert with it a gradually increased pressure, thus the abdominal viscera pushing the diaphragm upwards, the child exerts its power to overcome this impediment by a more extensive inspiration. If this act is prevented by pleuritic pain, we perceive it by its anxiety or irascible struggle with its trunk and hands, and by moans and cries, as far as they are possible. In this manner we should always assist the physical examination of the organs of the chest. The *percussion*, on the contrary, is the most enlightening means of examination in children. The walls of their chest are thin and flexible, consequently we perceive more imme-

diately the sound of the pulmonary texture, and even its consistence.

If we are aware of the above-mentioned circumstances, by and by, with patience, careful exercise, and intelligent combination of all that we see and hear, and of all that we feel with our percussing fingers, we cannot fail to arrive at a high degree of certainty in this sort of diagnosis. A new practitioner must proceed in a very simple way. He must not attempt to discover scattered lobular pneumonia, or single tubercles; this is, in general, a matter of approximative induction or conclusion. The pathological knowledge of the respiratory organs is carried to-day to a certain minuteness, which makes the subject rather difficult to the understanding. My anatomical line and gradation is the following:—

Simple bronchitis.—Inflammation of the bronchial tubes of large and middle size.

Capillary bronchitis.—An extension of the former into the fine bronchial ramifications. The highest degree is—

Broncho-pneumonia—by some authors termed catarrhal pneumonia, by others vesicular bronchitis, which, taken anatomically, is all the same; and it is even difficult to draw a line of separation between capillary bronchitis and broncho-pneumonia, only we may apply this latter name, or its mentioned synonymes, to the highest degree of capillary bronchitis. As merely an appendix, or a somewhat higher degree, or neglected state of broncho-pneumonia, may be considered the—

Lobular pneumonia.—This consists in the hyperæmic, indurated, or suppurated state of either single scattered lobuli, in which case we say *scattered lobular pneumonia,* or there are a great many of them present in one part of the lung, and then we say *generalized lobular pneumonia,* and hence, then, the gradual transition to lobar pneumonia. The expression "mamellonous *lobular pneumonia,*" signifies a circumscribed indurated state of single lobuli; and with the term "*partial lobular pneumonia,*" French authors understand a lobular inflammation whose centre presents much hardness, but gradually less towards the periphery. These are pathological subtilties important in science, but less available in practice. Then we have—

Lobar pneumonia.—This is the phlegmon of the lungs; it takes a whole part of one or both lungs, with all its constituent elements, and begins in general in the finest parenchyma of the lungs, without, or at least frequently without, bronchitis. In all these forms of broncho-pneumonia and pneumonia, there can be a complication of tubercles, either scattered, or extensive infiltration. We can only conjecture at their presence. Tuberculous caverns are seldom found in little children.

Pleurodynia.—Pain in the pleura, without fever or inflammation.

Pleuritis.—I term the first stage of acute pleuritis *pleuritic transudation*; there cannot be any mistake in this term.

Carnification has just the same value as in adults, but is less frequent in children.

Now, I am sure, that for practical purposes we can limit our diagnosis upon the following points:—*Simple bronchitis*—numerous large râles, clear sound of percussion, much cough, free inspiration, free movement of the chest. Or, *broncho-pneumonia*—very much diffused large and fine râles, the vesicular murmur not always, nor everywhere, audible, the inspiration imperfect, the movement of the chest lessened, the sound of percussion less clear, in some cases even partially a degree of dulness. In this latter case, and by the more pertinacious course of the malady, we may suspect lobular pneumonia complicated with it; and if these fine râles and some dulness are perceived between the scapulæ, and the habit of the child scrofulous, we suspect tuberculosis. Or, there is a high degree of dyspnœa, the movement of the chest much impeded, no vesicular murmur in a large part of the chest, but around it some fine râles, or crepitation and respiration present, we are induced to suppose *lobar pneumonia.* Lastly, with regard to pleuritic affections. Impeded inspiration, with evident expression of pain in the countenance, without fever, denotes pleurodynia on that side where the chest moves less freely, and where we perceive, by auscultation, less distinctly the respiratory murmur. If, under these very phenomena, fever be present, we regard the affection as the *first stage of pleuritis.* If over the lower part of the lung, much dulness is present, no respiratory murmur, no râles nor crepitation, no bronchial respiration, this denotes a large *pleuritic transudation.* If the transudation is less, or begins to be absorbed, then râles appear, and bronchial respiration.

Gentlemen, these are the most important significations of physical symptoms of the respiratory organs important for practice, and attainable by the well-informed practitioner even in a tender child.

On the next occasion we shall speak on the symptoms of the heart, and proceed to those of the abdomen.

CASE OF POPLITEAL ANEURISM,

CURED BY PRESSURE ON THE FEMORAL ARTERY.

By W. WARD, M.D., Huntingdon.

Read at the Cambridge and Huntingdon Branch Meeting of the Association, held at Ely, June 17th, 1851.

Thomas Baker, of Spaldwick, aged 36, admitted into the Huntingdonshire Infirmary, March 13th, 1847. Has been for the last ten years of his life an ostler at an inn, and previously to that time a post-boy, and in the habit of drinking much beer, but has always had good health; is a stout muscular man, of sanguine temperament. In August last he first felt pain in the popliteal space and about the knee, which made him lame, but did not observe any swelling or pulsation. The pain and lameness then disappeared, but came on again three months ago. His wife then observed a pulsation under the knee, which had escaped his own observation; since that time it has gradually increased.

For the last month or five weeks the pain has much increased, especially at night, not being much complained of in the day time; but there has been much difficulty in moving the limb from a state of rest. When admitted the limb presented the following appearance:—In the popliteal space of left leg there is a somewhat diffused swelling, which has a distinct pulsation through its whole extent, especially on the outside. Upon compressing the femoral artery the pulsation ceases, and the tumour diminishes in size; the stethoscope gives a distinct bruit de soufflet; the tumour appears about the size of a small egg; there is great pain felt in the tumour, which prevents his sleeping at night; the general health is good; the heart's sounds are normal; the posterior tibial can be distinctly felt, although pulsating feebly; the anterior tibial more feeble, and not so distinct.

19th.—For the last day or two there has been increased pain and swelling in the integuments and cellular tissue over the inner hamstrings, but apparently not connected with the aneurismal tumour. In consequence of the success which has attended the treatment by pressure of late, especially in two cases by Mr. Storks (*vide Lancet*, May, 1846), and this case appearing favourable, from the small size of the tumour and general good health and age of the patient, this treatment was adopted. Signorini's tourniquet was applied over the superficial femoral, at the upper-third of the thigh, not to completely stop the circulation, but only to impede it, the intention being not to apply pressure too forcibly at first. It was borne very well for a few hours, when the tourniquet was slightly slackened by the patient. Before the application of the tourniquet the temperature of the affected limb below the knee was lower than the sound one; three or four hours afterwards the temperature increased, and became higher than the other, and a slight swelling of the foot and leg appeared.

20th.—Had no sleep; at intervals has tightened and slackened the tourniquet; the posterior tibial can be felt beating distinctly; there is slight œdema of the limb. The circumference of the sound limb is thirteen inches and a half, that of the affected seventeen inches, measured round the knee. Ordered an aperient. Pulse 80; tongue clean; slight thirst.

21st.—Slept tolerably well; there is considerable swelling of the leg; bowels open from an aperient.

22nd.—Slept but little; obliged to slacken the tourniquet, or could not sleep; pulse 84; slight thirst; the temperature of the leg higher than the sound one; felt much ease from the application of Goulard lotion to the foot and leg. Size of the limb seventeen inches. On removing the pressure, pulsation of the tumour more feeble than before it was applied. The posterior tibial artery cannot be felt, probably owing, in part, to the swelling of the foot.

This treatment was continued, with variation of the pressure according to circumstances.

April 22nd.—For the last three weeks he has had no pain under the ham, and the aneurismal tumour has considerably diminished, and so altered in its character as to leave little doubt that the aneurism is becoming obliterated. Pulsation in the posterior and anterior tibial cannot be felt. During the whole of this month slight pulsation could occasionally be felt, and pressure was continued, with occasional intermission.

In the middle of June, some slight pulsation with bruit still continuing, the pressure, which had been left off, was reapplied. This was continued for three weeks, when no further pulsation could be felt.

August 28th.—There is now little or no swelling to be perceived in the ham; no pain upon walking; no pulsation. There is a slight bruit to be heard when the leg is flexed, and the stethoscope pressed deeply into the popliteal space; but this is probably produced by the compact coagulum around the artery.—Discharged.

June, 1851.—Up to the present time continues perfectly well.

Hospital Reports.

BIRMINGHAM GENERAL HOSPITAL.

CASE ADMITTED UNDER THE CARE OF J. HODGSON, ESQ.,

(Reported by ALEX. H. PATERSON, Esq., Altringham)

Gun-shot Wound of Thigh, with injury of the Neck of the Femur.

Edward Miller, aged 18, glass-maker, admitted into the Birmingham General Hospital, November 2nd, 1845. On examination, a wound about two inches in diameter was found in his glutei, behind and a little external to the hip-joint. It was bleeding freely, appeared about three inches deep, and on being probed by the finger was found to contain a great number of shot, some wadding, and so many splinters of bone, that the surgeon who first examined it considered the trochanter and neck of the femur to be blown to pieces. The boy said that, being out shooting, he had, when clambering through the gap of the hedge, held his gun behind him by the upper part of the barrel, and that the piece had gone off, the whole of the charge being lodged in his right thigh.

Ordered a yeast poultice to the wound, and to lie on his chest. The bleeding soon ceased, most of the shot, the wadding, and some of the splinters, were removed by the finger.

3rd.—Passed a bad night; bowels confined; face rather flushed; tongue moist and white; wound very painful, filled with dark blood, some of which has discharged into the poultice.

4th.—Passed a bad night, general symptoms much as yesterday. No tenderness in the abdomen; pulse 106, not hard; bowels open. Ordered a glass of wine daily, and three grains of carbonate of ammonia every four hours in an ounce of camphor mixture.

5th.—Passed a bad night and otherwise much the same. Ordered half an ounce of castor oil, and an enema. This acted freely in the evening.

7th.—Slept pretty-well; appetite pretty good; feels much more comfortable; wound discharges healthy matter freely.

9th.—Going on well; tongue still furred. The house-surgeon enlarged the wound three inches and extracted several shot.

11th.—The wound now looks quite clean, and is rapidly filling with healthy granulations There is a sinus extending a short distance down the thigh.

13th.—Continues to improve, but complains of much pain in the stomach. Omit wine.

18th.—Going on well. Omit poultice; the wound to be closed with sticking plaster, and covered with water-dressing.

24th.—General health pretty good. Wound filled with granulations, and much reduced in size. A small sinus appears in one part of it, and probably communicates with the bone. Is able to flex and extend the limb.

December 18th.—Continues much the same. Wound slowly heals.

January 24th, 1846.—Free motion in the limb, but unable to bear much weight on it. External wound not quite healed. From this time I lost sight of the case, but believe that after the discharge of some fragments of bone the patient recovered.

Remarks.—The patient in this case was young, thin, and suffered from considerable hæmorrhage before he reached the hospital; but allowing for these favourable circumstances the amount of reaction was very slight, particularly when it is considered that a charge of shot was lodged in and around the great trochanter, and that the capsular ligament can scarcely have escaped some injury. The treatment was very simple, and in my opinion very much more successful than an immediate dilatation of the wound for the minute examination and removal of the splintered bone, &c., would have been. I give the testimony of the gentleman who first examined the case respecting the extent to which the bone was splintered. The eminent surgeon, (Mr. Hodgson,) whose case it was, decided that the bone, though splintered, could not have been broken through, as there was no shortening of the limb, and motion was so soon restored in it.

Provincial Medical & Surgical Journal.

WEDNESDAY, JULY 9, 1851.

Our readers will perceive by a letter published at another page, that a Dr. Hilbers, of Liverpool, has come to the rescue of Mr. Hale, of Norwich, upon whom we thought it right to animadvert for his dishonesty in obtaining a degree from the University of St. Andrew's, by exercising what he, in the *Lancet*, calls by the mild term of "reserve," as to his homœopathic sentiments. Much as we consider Mr. Hale to blame, we pity him for his defence; for his advocate, so far from dispersing the moral cloud in which his conduct has enveloped him, has but given it a more sombre tint. He admits, in fact, that equivocation is justifiable, when it is necessary for obtaining a given end. His argument, if argument it can be called, amounts to this:—Any individual, who is acquainted with the present state of medical science, and with the recognized principles of treatment therein involved, (which, be it understood, he affects to repudiate,) but who is also a believer in homœopathy, and as such, knows something of billionths, trillionths, and other more impossible doses of drugs, is justified in order to gain a specific object, in suppressing this supererogatory knowledge, and exhibiting so much and no more as shall be satisfactory to the examiner. And a very pretty argument it would be, if this information which he possesses over and above the examiners, were admitted by them as truth. But when it so happens that what Dr. Hilbers calls extra *knowledge*, is not only not admitted by the examining body to be truth, but is regarded by them as a mischievous fallacy, which, if fairly acted upon in *real* disease, is pernicious to the welfare of the community, what becomes of the argument? Is there no difference between the suppression of supererogatory knowledge known and admitted to be such but not required, and the suppression of that which is considered to be an error, and the practice of which is held as a disqualification for the object sought? Knowing, as a homœopath must know, that the latter is the view in which his tenets are regarded, and being moreover, aware, as he must be aware, that the University, whose honours he was ambitious of possessing, would infallibly have refused those honours, had his sentiments been candidly avowed, not even the sophistry of Dr. Hilbers can make it appear that it was consistent with honourable principles to obtain a diploma as has been done in the case in question. If Dr. Hilbers cannot see this we are sorry for him; it merely shews the truth of the adage, "*facilis descensus averni;*" his own conscience, from his first lapse from the principles of medical practice, which have received the sanction and have been elaborated by the highest intellects of successive ages, must have sadly lost the fine sensibility which is the characteristic of the man of honour.

Should we be thought too severe in our expressions, we invite Dr. HILBERS to put this case to any gentleman of character, or to a clergyman :— I am in want of a certain honorary distinction, in the gift of a certain university, but my principles are such, as if they were known, would assuredly prevent my obtaining the object of my wishes. Am I, as a Christian and a gentleman, when interrogated with the express intention of testing those principles, justified in disguising them? This is the simple moral proposition, divested of the flimsy sophisms by which Dr. HILBERS has sought to surround them. Let him honestly put this question, and we venture to affirm that, from any member of the sacred profession, or from any right-minded man, he will have but one answer.

We would remind Dr. HILBERS, that in our remarks upon Mr. HALE, we did not find fault with him for his belief in homœopathy; we were willing to concede that he was one of the few who were honest in their convictions on that matter; we blamed him only for what we considered a wilful act of deception. But as Dr. HILBERS has challenged us to state whether our opinion that homœopathy is a humbug is derived from actual experimentalization in its absurdities, we do not hesitate to answer in the negative. We have never thought it requisite to torment the bowels of our patients with Morrison's pills, nor to anoint them with Holloway's ointment, as a necessary preliminary to our condemnation of those particular forms of quackery; why should we make an exception in favour of homœopathy for which there is even less appeal to common sense, and which is utterly repulsive to logical induction. We presume that Dr. HILBERS abjures Mahomedanism; has he thought it necessary, before so doing, to examine carefully into the tenets of Mahomet, and to study the Koran?

But though we have not ventured for the sake of pandering to the depraved taste of the *blasè* votaries of fashion, who would fly to anything for a new sensation, or of the silly multitude, who take *omne ignotum pro magnifico*, to trifle with those who confide in our judgment; we have both in public and private practice seen but too many instances of health frittered away and life lost, under the wretched system which Dr. HILBERS advocates. Bitter have been the lamentations, and severe the self reproaches of many, in our own personal knowledge, for suffering themselves or those dear to them to be the victims of this inanity. We have seen tubercular disease allowed to hurry, unchecked, through its fearful stages, the credulous patient believing the dictum of his homœopathic oracle, that he had been poisoned with mercury. We have seen trifling dyspepsia, that a first year's student would have cured, allowed to subside into confirmed anæmia; we have cured in four or five days, ailments that had been globulized unavailingly for six months. But we are free to confess that, had we not witnessed these warnings, we should still have pinned our faith to principles which have had the sanction of a Sydenham, a Baillie, and an Abercrombie, and are maintained by a Chambers, a Bright, and a Williams, rather than be attracted by a pseudo-science, which in this country is supported either by men whose only notoriety is that which it affords, or who have previously been distinguished for their adoption of any and every charlatanism, by which, for the time being, the public could be deluded.

Dr. HILBERS demands a refutation of the homœopathic doctrines They have been refuted over and over again, in a manner which would satisfy any mind capable of comprehending a logical disquisition, or which is not warped by self-interest. We will neither waste our own time, nor weary the patience of our readers, by a further attempt to expose the errors of a system, of which, in spite of their magniloquent assertions to the contrary, it is so clearly the object of its professors not to be convinced. In a man who can believe and practice homœopathy, in our deliberate opinion, either intelligence or conscientiousness must be deficient; an appeal to either would therefore be entirely thrown away.

Reviews.

Portraits of Diseases of the Skin. By ERASMUS WILSON. FASC. IX.

Pathology of the Human Eye. By JOHN DALRYMPLE, F.R.S., &c. FASC. VII.

Surgical Anatomy. By JOSEPH MACLISE, F.R.C.S.

THESE splendid works proceed with unprecedented regularity, and with no falling off in practical value, or faithfulness and beauty of execution.

Mr. Wilson's work contains illustrations of the

following diseases:—lichen solitarius annulatus; lichen syphiliticus confectus; roseola annulata, and psoriasis guttata.

Mr. Dalrymple's seventh number embraces the subject of the varieties of cataract and the operation of depression. It is impossible to speak too highly of the life-like accuracy of the drawings.

In the present number of the "Surgical Anatomy," Mr. Maclise gives four plates illustrating the operation of lithotomy, and congenital and acquired malformations of the urethra and prostate gland. The next number is to conclude the work, which, from its cheapness is, or will be, we doubt not, in the hands of every scientific surgeon.

Proceedings of Societies.

MEETING OF THE SUFFOLK BRANCH.

The anniversary meeting of the above Branch of the Association was held at Framlingham, on Friday, the 27th of June. The meeting was held in the Town Hall, a spacious and commodious room, which is built within the ruins of the ancient and far-famed castle. There were several reasons which conspired to prevent the members of the Association from attending the meeting, the principal of which was the attraction of the Great Exhibition. Severe and important cases kept away some of our valued associates, but notwithstanding, it will be seen that the attendance was fair, and the contribution of papers and cases supported the scientific character to which our Suffolk Branch, we think, fairly lays claim.

The following members were present:—Dr. Durrant, Ipswich; Dr. Kirkman, Melton; Dr. Chevallier, Aspall; Dr. Millar, Eye; Wm. Jeaffreson, Esq., Framlingham; C. G. Read, Esq., Stradbroke; H. L. Freeman, Esq., Saxmundham; R. V. Gorham, Esq., Aldborough; E. Gross, Esq., Earl Soham; J. Beales, Esq., Halesworth; Wm. Muriel, Esq., Wickham Market; Chas. Marshall, Esq., Woodbridge; J. C. Edwards, Esq., Ipswich; P. Weston, Esq., Yoxford: John Wilson, Esq., Framlingham; C. R. Bree, Esq., Stowmarket.

At two o'clock the chair was taken by Dr. Kirkman, who, on having addressed the meeting resigned it to Wm. Jeaffreson, Esq., who spoke at some length and with much kind feeling upon the honour of being called upon to preside at the meeting.

Mr. Bree then read letters of apology for non-attendance from Dr. Baird, W. Image, Esq., (enclosing his annual subscription of £5. 5s. to the Benevolent Fund,) Dr. Ranking, J. Manning, Esq., J. Growse, Esq., R. Growse, Esq., Dr. Growse, W. E. Crowfoot, Esq., John Gissing, Esq., W. C. Worthington, Esq., W. Davy, Esq., C. Mann, Esq., G. Baker, Esq.,

The following papers were then read to the meeting:—

1. A successful "Case of Operation for the removal of an Ovarian Tumour, weighing twenty-six pounds, by the Large Incision." By John Beales Esq., of Halesworth.

2. A "Case of Diseased Bladder." By R. V. Gorham, Esq.,

3. A severe "Case of Diseased Neuralgia of the Face, successfully treated (after all other remedies had failed) by Cod-liver Oil." By Dr. Durrant.

The relation of this case brought out the following remarks from members present upon the remedial powers of this valuable remedy:—

a. Its successful use in the treatment of hœmorrhoids, administered internally, by Dr. Durrant.

b. Two cases of phthisis pulmonalis as diagnosed by well-known stethoscopists, cured by cod-liver oil, by C. R. Bree, Esq.

c. Its successful use in the treatment of chronic rheumatism, by John Beal, Esq.

d. A case of phthisis pulmonalis, in which great improvement had resulted and was still going on from the internal administration of almond-oil, by H. L. Freeman, Esq.

The President asked if any member had any experience of its use in sciatica, and no answer being given to the question,

Mr. Bree related a severe and long protracted case of sciatica, in which quinine in large doses, iodide of potassium, aconite and belladonna (externally), acupuncturation, blisters, &c., had failed, which was entirely cured in a fortnight by the unguentum veratriæ, ten grains to the ounce, rubbed in every night with a horse-hair glove.

4. A most interesting "Case of Fungoid Disease of the Dura Mater, running its course and proving fatal in six months, illustrated by the Preparation and well-executed Gutta Percha Models." By C. B. Read, Esq.

5. A "Case of Stricture of the Urethra." By Wm. Jeaffreson, Esq.

Dr. Kirkman mentioned a "Case of Hay Fever," occurring in his own family, which had resisted all treatment. Dr. K. promised to detail the case, with some remarks upon this curious disease, at the next meeting.

The following resolutions were then passed unanimously:—

Proposed by Dr. Durrant, seconded by H. L. Freeman, Esq.,—

"That this meeting regards, with the utmost satisfaction, the resolution passed by the College of Surgeons on the 19th and 24th of March last, upon the subject of Medical Reform; and entirely concurs in the spirit of the memorial presented by the Central Council of the Provincial Medical and Surgical Association to Sir George Grey upon this subject."

Proposed by Dr. Chevallier, seconded by J. V. Gorham, Esq.,—

"That the place of meeting of the Suffolk Branch of the Provincial Medical and Surgical Association for

1852 be at Stowmarket, and that Dr. Bedingfield be requested to preside."

Proposed by Dr. KIRKMAN, seconded by C. GROSS, Esq.,—

"That the best thanks of this meeting be presented to those gentlemen who have read papers and cases."

Proposed by Dr. MILLER, seconded by C. READ, Esq.,—

"That the best thanks of this meeting be presented to the Masters and Fellows of the Pembroke College, Cambridge, for the use of the Town Hall for the purposes of this meeting."

Proposed by G. R. BREE, Esq,, seconded by W. MURIEL, Esq.,—

"That a memorial be presented to the Central Council, requesting them to take into their consideration the eligibility of holding the Annual Meeting of the Parent Association at Ipswich, the first vacant year after 1852, and that the following gentlemen do form a Committee, to draw up and present this memorial to the Council at the ensuing meeting at Brighton:—Mr. Jeaffreson; Dr. Baird; Mr. Martin, Holbrook; Dr. Kirkman; and Mr. Bree."

The following gentlemen were elected members of the Association:—Charles Marshall, Esq., Woodbridge; John Wilson, Esq., Framlingham; Thomas Jarmain, Esq., Holbrook; Robert Rowe Corley, Esq., Laxfield. And the following were recommended to be added to the Council:—Dr. Wake, Southwold; Wm. Edward Crowfoot, Esq., Beccles. Votes of thanks were then passed upon the President and Secretary, and the meeting separated.

Between twenty and thirty members and their friends sat down at five o'clock to an excellent dinner at the Crown Hotel, Mr. Jeaffreson in the chair, supported by the Rev. Mr. Attwood, Drs. Durrant, Kirkman, Chevallier, &c., and thus ended a very pleasant and agreeable meeting.

MEETING OF THE

CAMBRIDGE AND HUNTINGDON BRANCH.

THE annual meeting of the Cambridge and Huntingdon Branch was held at Ely, on Tuesday, June 17th. Between thirty and forty members were present, including Dr. Ward and Mr. Isaacson, of Huntingdon; Dr. Whiting and Mr. Sayle, of Lynn; Dr. Webster, Mr. Carter, Mr. Johnson, and Mr. Humphry, of Cambridge; Mr. Muriel, Mr. Robert Muriel, and Mr. Jones, of Ely; Mr. Girling, St. Ives; Mr. Newton, Alconbury; Mr. Pinchard, Cottenham; Mr. Hitch, Fulbourn; Mr. Calver and Mr. O'Connor, March; Mr. Faircloth and Mr. Peck, Newmarket; Mr. Porter, Peterborough; Mr. Steele, Stoke Ferry; Mr. Joy, Northwold; Mr. Archer, Feltwell; &c., &c.

Dr. Ward, of Huntingdon, vacated the chair in favour of Mr. Muriel, of Ely, who had been chosen president for the ensuing year.

Aortic and Popliteal Aneurism; Excision of the upper end of the Humerus and Femur; Discussion on Chloroform; Tubal Pregnancy; Deficiency of Abdominal Parietes and fore-part of Bladder; High Operation of Lithotomy.

Mr. HUMPHRY, of Cambridge, exhibited a specimen of aneurism of the commencing part of the descending aorta, which projected the left pleura, and had made its way through the ribs, so as to form a swelling on the left side of the spine. The coverings of the tumour were formed by the lung which was adherent, and condensed over it, by the pleura, the muscles of the back, and the vertebræ. It had no distinct lining, but the several parts forming its wall were coated by a thin layer of lymph, or by laminated, loosely-adherent fibrinous coagula. The bodies of four vertebræ were deeply excavated by the pressure of the blood, their exposed surfaces being rough and uneven, like those of an ulcerated bone. The intervertebral substances stood out in strong relief, having undergone very little change. The theca of the spinal cord was exposed for nearly two inches. The ribs were destroyed as far as their angles, and their rough extremities projected naked into the aneurismal cavity. The opening from the aorta, situate one inch and a half below the left subclavian, was round, an inch in diameter, with thick smooth edges; the inner coat of the artery was sharply everted, and continued for a short distance into the interior of the sac, but was soon lost.

The patient, aged 54, had been attacked in October, 1849, with pain in the left side and shoulder, thought to be rheumatic; it was very severe, and was only partially relieved by blisters and other treatment. In March, 1850, his wife discovered a swelling on the left side of the spine; this swelling was soft, and pulsated, but no bruit could be detected. He died September 3rd, 1850. Two months before death he was so much better as to be able to go to work in the fields. Paraplegia came on suddenly two weeks before death. He had been in the army many years. Had served twelve years in India, where he had rheumatic fever. In the last few years had been a farming labourer in England.

The specimen was an illustration of the havoc which ensues when, owing to accident or disease, the elastic coats of an artery give way and cease to retain the current of blood within its proper channels, no other tissue being capable of resisting the impulse of the blood. The absence of bruit was probably dependent upon the character of the opening into the aneurism, and upon the flow of blood through it being slow. The previous occurrence of rheumatic fever is worthy of remark, because aneurism of the aorta and other arteries is not uncommonly traceable to that disease.

Dr. WEBSTER wished to call attention to the position which coagula occupy in aneurismal sacs. He had observed that they were often situated, not as is generally stated, in the parts where the blood is most at repose, but in other places, the locality being probably determined in many instances by some inflammatory condition of the interior of the sac.

Dr. WARD related the particulars of a "Case of Popliteal Aneurism, cured by Pressure upon the Femoral Artery." (Printed at page 373.)

Mr. HUMPHRY also related a case of the same kind.

Mr. SAYLE produced the diseased upper end of a humerus, which he had removed from the stump of an arm by an incision through the deltoid muscle. He had performed this operation in preference to amputation at the shoulder-joint, in the hope that the remaining soft parts, in which some bone had been deposited, would admit of the application of an artificial limb. So far as the case had at present gone it appeared to justify his expectations.

The same gentleman also produced the ulcerated upper extremity of a thigh bone which he had removed from a patient with diseased hip. The head and considerable part of the neck had been destroyed by ulceration. Though the incision healed, an abscess had formed subsequently in the pelvis and the case had not been, on the whole, quite satisfactory.

In a discussion which then ensued upon the subject of "Chloroform," Mr. HUMPHRY said there could be no doubt that the vapour is transmitted through the medium of the blood, and brought into direct contact with the nervous centres, the several parts of which it affects, in the order of their susceptibility to impressions, viz., 1st., the sensorial; 2ndly, the emotional; and 3dly, the reflex; in the same manner as alcohol, ether, and other agents of that kind. Like them, it first stimulates and subsequently exerts a depressing or paralyzing influence. The vivid ideas, the perception of brilliant lights, of various sounds, the dreams and restlessness, succeeded by gloom, quiet, and insensibility; the laughter, crying, and struggling, succeeded by complete tranquillity; the deep quick breathings, followed by snoring, stertor, and suspension of respiration, are the result of the stimulating and depressing influence exerted upon the several parts of the nervous system in succession. The great danger in its administration consists, not, as the ultra-advocates of chloroform would have us to believe, in suffocation from the exclusion of atmospheric air, so much as in surcharging the blood with a quantity of the agent, whereby the different parts of the nervous system are paralyzed in rapid succession, and a powerful influence is exerted upon the reflex functions, before time has been allowed to observe its operation upon the sensorial. Care, should, therefore, be taken not to administer it too rapidly, more particularly when the patient begins to show signs of falling under its influence. Especial caution is required during the stage when the inspirations are deep and quick, because a large quantity is then likely to be inhaled in a short time; and the inhalations should be discontinued when snoring occurs, because it is an indication of commencing paralysis of that part of the reflex apparatus which presides over respiration. It is rarely necessary to proceed to this extent, complete insensibility, being produced and maintained by careful management without affecting the reflex system; indeed it is not essential to paralyze the emotional tract for the sake of preventing pain, though it is often desirable to do so for the purposes of the operation. Another danger resulting from the use of chloroform is severe fainting, when its influence is passing off. He had seen this to a very alarming degree in a few cases, and in one instance, where insensibility had been maintained through a tedious operation for the removal of necrosed bone he had found it necessary to resort to artificial respiration; after this had been continued for a few seconds natural breathing returned. In most cases dashing the face with cold water suffices to restore the patient, and Mr. Humphry had not yet witnessed any immediate disastrous results or any after ill consequences from the use of chloroform. Its influence is most easily induced in patients who are delicate or debilitated by disease or loss of blood, and is peculiarly valuable in these cases by lessening the shock of the operation. With regard to the cases suitable for its administration, Mr. Humphry was of opinion that the instances are few in which a patient fit to undergo a capital operation, may not have the benefit of chloroform provided due care be employed in its use. He was by no means prepared to say that even under the most cautious management, fatal results will not now and then occur, but he was of opinion, that on the whole, the success of operative surgery is increased by the judicious employment of anæsthetic agents. He had given it internally in half-drachm doses, with immediate and permanent benefit in some cases of severe spasmodic pain; in others it had been productive only of temporary relief, and in others it had quite failed. Indeed it seems that we cannot calculate with certainty on a beneficial result from the internal administration of chloroform in any of those affections in which it has been tried, such as spasmodic pains, tetanus, delirium tremens, &c.; its effects being very variable in all these diseases.

Dr. WHITING and Mr. SAYLE had used chloroform in the Lynn Hospital in nearly every important operation, and had seen no evil results. They were both of opinion that the wounds bled rather more freely when the patients were under its influence.

Dr. WEBSTER had administered chloroform in a great number of cases, and spoke of the necessity of subjecting the patient slowly and cautiously to the influence of the agent. During the return of the patient to his natural condition, the several parts of the nervous system may be observed to recover their sensibilities in the inverse order to that in which they had been deprived of them. He had given chloroform internally with good effect in some cases of delirium tremens.

Mr. JOHNSON related a case of severe delirium tremens in which, after opium had failed, he gave chloroform, at the suggestion of Dr. Webster, with very great benefit.

The SECRETARY read the particulars of a "Case of Tubal Pregnancy," forwarded by Mr. Peck, of Newmarket. The patient, a single woman, aged 21, was seized with sickness, faintness, and pain in the body, and died in 14 hours. A large quantity of blood was found in the abdominal cavity, and a fœtus of four months which had escaped from a pouch formed of the dilated

fallopian tube; that pouch was lined by placenta. The uterus presented a thickened deciduous membrane, and the os was closed by a quantity of gelatinous substance.

Mr. PINCHARD introduced a male child, five years old, with congenital deficiency of the fore part of the bladder and abdominal parietes. The hypogastric region was occupied by a vascular mucous membrane, which was the posterior surface of the bladder; upon this the ureters opened, and the urine was continually trickling away. The penis, in a state of epispadias, projected from the fore and under part of this mucous surface; and beneath the penis, corresponding in situation and appearance with the scrotum, was a considerable swelling, extending transversely across from side to side, and looking as if caused by two large scrotal herniæ meeting in the middle line. The testicles could not be felt, perhaps because the child was so restless that no accurate examination could be made. There was a deficiency of the fore part of the bony structure of the pelvis. No umbilicus was visible.

Of this malformation several examples have been described, corresponding very closely with the present. It depends upon an imperfect formation of the bladder and ureters, which are developed from the lower part of the allantois; hence the deficiency extends up to the umbilicus, which is involved in the malformation, but has no relation to the other abdominal organs. The fore part of the abdominal wall, corresponding with the bladder, including the pubic bones is also deficient in development.

The lad, Thomas Sutton, who underwent the "high operation of lithotomy," in Addenbrooke's Hospital, Cambridge, in September, 1848, and whose case is reported in the seventeenth volume of the "Transactions" of the Association, was present. He was in perfect health; able to work in the fields. There was a slight bulging at the lower part of the abdomen, though the divided linea alba and recti muscles had reacquired strong attachment to the ossa pubis, and no inconvenience whatever results from the operation.

It was determined that the next meeting should be held at St. Ives, in June, 1852; Mr. Girling having consented to preside on the occasion.

MEETING OF THE

NORTH-WALES BRANCH.

THE annual meeting of the North-Wales Branch of the Provincial Medical and Surgical Association was held in the Board Room of the Infirmary, at Denbigh, on Tuesday, June 17th. There were present,—Dr. Lloyd Williams, of Denbigh, President; Dr. Edwards, of Chester; Dr. Hughes, of Mold; Dr. Edward Williams, of Wrexham; Dr. John Roberts, of Bangor; Dr. Williams, of Mold; Dr. Pierce, of Denbigh; Dr. Turnour, of Denbigh; Dr. Chambers, of Denbigh; Dr. Roberts, St. Asaph; Mr. John Lloyd, of Llangefni; Mr. Kent Jones, of Llangefni; Mr. Richards, of Bala; Mr. Robert Jones, of Carnarvon; Mr. Price Jones, of Rhyl; Mr. Peter Norcliffe Roberts, of Denbigh; Mr. Llewelyn Lodge, of Rhyl; Mr. Green, of Buckley, near Mold; Mr, Hughes, of Bangor; Mr. Roberts, of the Infirmary, Denbigh; Mr. Jones, of the Asylum, Denbigh; and Mr. Owen, of Abergele.

The PRESIDENT opened the business in the following address:—

Gentlemen,—When I inform you that I am only just beginning to crawl about after a severe attack of that most prostrating complaint—influenza, I feel assured you will more readily pardon the inefficiency for which, at any other time, I should have had to crave your indulgence; indeed, nothing but a deep sense of the honour conferred upon me in being selected as your president for this meeting, and my anxiety to meet your wishes, and to perform the duty imposed upon me to the best of my feeble powers, would have induced me to undertake the responsibility of presiding upon this present occasion. The objects of this Association have been so ably and eloquently set forth to you by one much more competent than myself, and to whose zeal and kindness we are mainly indebted for the formation of this branch of the Society, that I will not enter upon so hackneyed a subject. If the benefits derived from the formation of this Association went no further, it would be sufficient that it brought us together for the purpose of social and friendly intercourse, and to value our better acquaintance with each other. I feel, gentlemen, that some little account of my stewardship as an old—perhaps the oldest—surgeon within the circle of our Association, will be expected of me upon this occasion, and I think the best way I can evince my gratitude to you for your kindness in selecting this town for the locality of your meeting, is very briefly to relate a few of the most interesting cases which have fallen under my care during the thirty-six years I have held the appointment of Surgeon to the Denbighshire Infirmary. I take shame to myself that I have allowed so long a period to elapse without making some of these cases public; nothing but our meeting to-day would, probably, have stimulated me to relate them. I hope my younger brethren will avoid the indolence of which I plead guilty in having neglected to keep more faithful records of important cases than I have done. I regret to say, that beyond the records of the case-book I have nothing to refer to, and consequently my dates are very defective. (These cases will be hereafter published.)

Mr. LLOYD, the treasurer, read a statement of the accounts, which were passed.

Dr. Hughes, of Mold, was unanimously elected President for the ensuing year, and it was resolved that the next annual meeting should be held at Conway.

The honorary secretaries and treasurer were re-elected, and the following gentlemen were named for the District Council:—Dr. J. Roberts; Dr. Edwards; Dr. O. Roberts, of St. Asaph; O. Richards, Esq.

The following resolution was also proposed and carried unanimously:—

"That the members of the North-Wales Branch, assembled at their annual meeting in Denbigh, having taken into consideration the subject of Medical Reform, do approve of, and entirely concur in, the steps taken by the Council of the Parent Association, as expressed in the memorial recently presented to Sir George Grey,

and unite in hoping that the present unsettled and divided state of our profession may speedily receive that attention and wise legislation which the importance of the subject demands."

The party at the close of this meeting adjourned to the house of Dr. Lloyd Williams to lunch, and then visited the North Wales Lunatic Asylum, under the guidance of that gentleman, expressing themselves highly delighted with the elegance of the structure, the beauty of the site, the cleanliness, order, and comfort observable in the interior, and the care bestowed upon the unfortunate inmates.

At half-past four o'clock they reassembled at the Crown Inn, where an excellent dinner was provided—Dr. Loyd Williams presiding, and Dr. Edward Williams acting as vice-president.

The usual toasts—"The Queen," "Prince Albert and the rest of the Royal Family,"—having been drank, the PRESIDENT called for a bumper, and proposed "Prosperity to the Provincial Medical and Surgical Association." He said he should not enter upon the great advantages which they had derived from its formation. These had already been described to them in much more lucid and eloquent terms than he could employ, by his predecessors in office; but he must say that amongst its other good results was that of the members of this branch being brought together, at least once a year; and he hoped that this would be continued when the voice which now addressed them would be at rest. They would then become better acquainted with each other; they were enabled to exchange the information which they had gained in the course of their practice, and thus assuage the sufferings of their patients; they would have an opportunity of reconciling any personal differences which might exist, and in so numerous a profession they could scarcely expect to be altogether free from such differences, and emulation and honourable rivalry would be excited. He trusted that they would, individually and collectively, endeavour to make their profession as honoured as it was honourable, and to foster those kindly feelings which they were called upon as Christians to cultivate towards each other, and thus to elevate still further a profession whose objects are the restoration of that blessing, for which, as Dr. Abernethy used to say. "sick kings would gladly give their diadems." In connexion with the toast he would give them the health of "Sir Charles Hastings." Drunk with much applause.

The PRESIDENT next gave, with a high eulogium upon his character and talents, "The President of the past year, Dr. Cumming," whose absence they much regretted; which was drunk with enthusiasm. He then said as they had worshipped the setting sun, it was now their duty to turn their faces and pay their homage to the rising sun—"The President of the next year, Dr. Hughes, of Mold," whose health they would also drink in a bumper, Were that gentleman not present he should say a great deal about him that he could not now utter; but he might, perhaps, be permitted to add that he had been in the habit of meeting him in consultation during a long series of years, and he was so indefatigable, and his professional knowledge was so extensive, that he invariably left him nothing to do or to suggest. The toast was drunk with honours.

Dr. HUGHES thanked the President and the company for the glowing and complimentary manner in which they had received his name, and also for the honour which they had done him in electing him their President. The task which they had imposed upon him was not so easy, considering that he came after his talented and skilful seniors, who had discharged their duties in the most superior manner; but now, as ever, his best endeavours should be directed to the promotion of kindly feelings amongst his brethren of the profession, not one of whom had he knowingly or wilfully injured. Meetings such as this and that of last year would make him ashamed of himself had he done so. Some fifty years ago had a number of medical gentlemen met together in this manner they would have constituted a sort of happy family, exchanging cat and dog greetings. The better class of the profession in his time had always behaved well, but still there were some who would pick holes in each other's coats through envy. Now he was glad they found the necessity of exerting themselves to prove their superiority to each other, and to obtain honours in their profession. He proposed the health of "the President," who had practised successfully during a period of thirty-six years. They had held their meeting that morning in the Infirmary, and where so fit a place as that in which his picture was deposited for the services which he had rendered to the charity, and the benefits which he had conferred on the community? Hence they proceeded, with feelings of no ordinary gratification to that splendid monument of his successful exertions in the cause of suffering humanity, the North Wales Asylum for the Insane, and surely he must have much pleasure in seeing visitors examine this solid momento of his zeal and kindly feeling.

Dr. JOHN ROBERTS warmly supported the proposition, and observed that even at a distance the President was known, not only as an ornament to the profession, but to the country. If not already, he ultimately would be, at the head of his profession in North Wales. All present fully appreciated his merits, and applauded his conduct; and they were glad to see him hale and vigorous, though advancing in life. To whatever years or honours he might attain, he would ever have the satisfaction of looking back on a life well and usefully spent.

The toast was drunk enthusiastically.

Dr. LLOYD WILLIAMS was so oppressed with a sense of the kind manner in which Dr. Hughes and Dr. Roberts had spoken of him, that he could not acknowledge the compliment as he wished. During his whole life nothing had been so precious to him as the good opinion of his professional brethren and that of the public; and now in the downhill of life, when he was falling into the sear and yellow leaf, these testimonies that he had succeeded in obtaining and retaining it, were especially valuable. Whenever he had met a professional brother in consultation, if he did not leave him on good terms with his patient it was not his fault; but he was happy to say that he had generally left him on better. This ought to be the endeavour of every man in his position. He could only reiterate his heartfelt thanks for the honour that had been done to him; and he should be glad to meet them again and

again, as he considered such gatherings of inestimable advantage to the profession. He concluded by proposing "The health of the Vice-President, the Honorary Secretary, and the Treasurer," with many thanks to them for their kindness, assiduity, efficiency, and constant attendance.

Dr. Edward Williams responded, and proposed the health of "Dr. Edwards and the other new Members," observing that he looked forward to much good being derived by the Association from the talent and information which Dr. Edwards was possessed of. Drunk with unanimity.

Dr. Edwards said he was highly complimented, not only by their drinking his health, but also by their having elected him a member of their Association. He greatly appreciated this opportunity of opening an intercourse with the profession of North Wales. Though he had not the privilege of calling himself a Welshman, yet, coming to settle amongst them, he was more especially gratified with this introduction. He had never expected, when he made up his mind to pay them a visit, to find so full a number of members at the anniversary meeting of their Association. He was last year the president of the Cheshire Branch of the Association, and he was somewhat surprised to see, in the small and inland town of Denbigh, a better muster than was made by that Association in the populous and thriving town of Liverpool. He had enjoyed much experience in such associations, and anticipated the best results from the operations of that which he had been permitted to join; and for the sacrifice which he had made in coming to Wales this meeting was a sufficient compensation. He trusted that as the next meeting was to be held at Conway, where he was about to take up his residence, there would be a very full attendance, and his zeal should not be found wanting in promoting the prosperity of the Association.

Dr. Hughes proposed the health of "Dr. Chambers and Dr. Turnour, as connected with the Infirmary," which was drunk and acknowledged.

The Chairman, with a high compliment to the attention which Dr. John Roberts devoted to the Anglesey and Carnarvonshire Infirmary, which he had no doubt would, under his fostering care, shortly rank as high as any in the country, proposed that gentleman's health, with "Success to the Institution."

Dr. John Roberts replied, and proposed "the health of Mr. Griffith, of Wrexham."

Mr. D. Kent Jones gave "the health of Mr. Charles Turner Jones, House-Surgeon to the Denbigh Infirmary," to whose merit the President also bore warm testimony.

Mr. Robert Jones, of Carnarvon, proposed "the health of Dr. Roberts, of St. Asaph," who responded, and gave "The Press," expressing a hope that its report of the proceedings of the day might induce those of the medical profession who had not yet joined the Association, to lose no time in doing so.

Mr. Martin, of the *North Wales Chronicle*, and Mr. Jones of the *Carnarvon Herald*, responded.

The President next gave "The health of Mr. Robert Jones, of the Asylum," eulogizing his Christian charity and kindness, and unabated attention to the patients, and noticing the high respect in which he was held by the people of the town in which he resided.

Mr. Jones returned thanks, and Dr. Edwards then endeavoured to incite the profession to a more numerous attendance at Conway, after which a plate was passed round for contributions to the Benevolent Fund, when the sum of £2. 2s. 10d. was collected.

The other toasts were "Mr. Price Jones," "Mr. Peter Roberts," and "Dr. David Hughes, of Mold," all of which were suitably acknowledged.

M. Lloyd, of Llangefni, mentioned that at the last meeting he had in his paper, alluded to the impropriety and the danger of the free sale of poisons being permitted. Since then the subject, at the instigation of the Association, had received the attention of the Earl of Carlisle, who had passed a bill rapidly through Parliament to check the evil. The noble lord has also been much concerned in sanatory improvement, and he should be sorry if this meeting passed over without some echo of their satisfaction and pride at its progress, especially as the measures were originated by the profession who were much interested in them.

EPIDEMIOLOGICAL SOCIETY,

June 2, 1851.

At the ordinary meeting of the Society, held this day, at the house of the Royal Medical and Chirurgical Society, Dr. Babington, the President, in the Chair, Mr. R. H. Cooke read a paper

On the Epidemic Mental Diseases of Children,

founded chiefly on Hecker's "Children's Pilgrimages" and "Sympathy." It commenced with an inquiry as to the propriety of applying the term epidemic to diseases of this class. The chief reason against it lay in the consent of the will, which was requisite to their production. The same objection, it was remarked, would lie against the application of any epithet of pathology to mental disorders. No medical observer of mental phenomena, however, would be disposed to grant to the will that freedom which may be claimed for it by the metaphysician; and the normal characteristic of childhood is the weakness of this self-determining faculty. At first wholly destitute of it, the infant is guided in its movements solely by instincts and stimulants acting upon the reflex nerves. The first impulse to voluntary movement is the instinct of imitation. The first articulations of the child are thus learned, and are only subsequently associated with ideas. This imitative instinct continues strong during childhood and youth, but becomes now an impediment, not a stimulant, to the will.

That this faculty should produce morbid results, it is necessary that, in the feelings or actions of the adults with whom the child is placed in communication, there be something morbid or overwrought.

How widely such a feeling may react upon children was remarkably shewn in the thirteenth century, during the era of the crusades. The popular ardour for the recovery of the Holy Land was still strong, though restrained by the indisposition of the governments. What the men could not do, the children undertook

Almost simultaneously, children of all ranks, some girls among them, collected from all parts of Germany and France, and marched in procession to various seaports on the Mediterranean. Many perished by the way. Most of those who reached the coast were sold into slavery. The number was estimated at more than 60,000.

In the delusions respecting witchcraft and similar commerce with the invisible world, which prevailed through Europe from the Reformation almost to our own day, the children participated. Some suffered death on their own confession of having familiar intercourse with Satan; and multitudes bore testimony, fatal because unquestioned, against those accused of such practices, swearing that they had been carried through the air by them, had seen their disguises and been privy to their secrets, and that they had been in various ways afflicted by them.

Allusion was made to the well-known convulsive epidemic in the Orphan House of Amsterdam, recorded and treated by Boerhaave.

It was observed that, notwithstanding the general mental excitement of the last half century, and the marked tendency to belief in the supernatural, there was no record of any occurrence similar to those first described; the nearest approach to it, in our times, was the attempt to enlist the children in the advocacy of total abstinence. From extensive inquiries respecting the Orphan Asylums, and the great educational institutions, there did not appear to be any prevalence of imitative convulsive disorders. These immunities were attributed to a better understanding of the position of children in society.

It was suggested that probably much of the epidemic constitution of the present time was due to the repressed excitability. Confessedly it was more nervous than at any previously recorded epoch.

Short of positive illness, there appeared to be an increasing asthenia during five or six years preceding the completion of physical development, apparently the result of exhaustion, and requiring much care, but commonly passing into full health and recruited energy.

In conclusion, it was observed, that the office of the medical practitioner and of this society, was not so much to cure these cases, as to direct the public attention to them with a view to their prevention. The evil was in the hands of parents and preceptors. It was suggested that, in some cases, there was an undue call upon children for aid in religious objects. It was, however, a most difficult problem how best to prepare the child to meet the excitement of the world. Probably the chief thing to be supplied was opportunity for bodily activity, combined with mental relaxation.

An animated discussion followed, in which Dr. Sibson, Mr. Hunt, Col. Sykes, Mr. Walsh, and Dr. James Bird took part.

At half-past nine Dr. Snow read the remainder of his paper

On the Mode of Propagation of Cholera,

commencing, however, with an abstract of the portion read at the former meeting. He enumerated many circumstances in the history of Asiatic cholera, and some particular facts, which he considered to prove that the malady was propagated by human intercourse, as, indeed, he believed all epidemic diseases to be. He stated his belief that there was no evidence opposed to the communicability of cholera, for the facts thought to bear this construction were only considered to do so on the assumption that if cholera be communicated, it must extend itself, as the eruptive fevers are believed to do, by means of some emanation given off from the patient into the surrounding air, or by contact with the patient or articles of clothing, &c., which have been near him. Nearly all the arguments which were thought to disprove the communication of cholera would apply equally well to syphilis, did we not happen to know the way in which it is communicated. He considered that cholera always commenced by a local affection of the alimentary canal, and that the constitutional symptoms were always the result of the local disorder. It followed, therefore, that being a communicated disease, and commencing by a local affection, the morbid poison must be applied to the part first affected; that, in short, the cholera poison must be swallowed—must multiply itself in the alimentary canal, and pass off in the fæces and matters vomited; and that the disease must be communicated by these evcuations being accidently swallowed: this being a method, however, by which the complaint might still be communicated, providing it did not begin in the alimentary canal, but by constitutional symptoms, like the eruptive fevers. He enumerated many circumstances giving a general support to this view of the propagation of cholera: one of these circumstances being its increased prevalence from want of personal cleanliness, whereby those waiting on the sick could not fail to contaminate the food which they ate themselves or prepared for others. Some particular instances of apparent communication of cholera by means of articles of food were also related.

The author continued to the effect that, in his opinion, cholera was likewise often communicated by means of drinking water, owing to the contents of drains and sewers being emptied, either accidentally or systematically, into the source whence supplies of water were taken. He related the particulars of many violent local outbreaks of cholera connected with the contamination of limited portions of water, and stated that the sudden way in which these outbreaks took place, immediately after the evacuations of one or more cholera patients entered the water, precluded the supposition that the impure water was merely a predisposing cause. The great prevalence of cholera in the south districts of London, and in many large towns, was connected with the drinking of river water into which sewers emptied; and in Rotherhithe and Bermondsey—the metropolitan districts in which cholera was most severe—many of the inhabitants had no supply of water except from certain tidal ditches which received great quantities of excrementitious matters. In the towns, such as Birmingham, in which this connection between the sewers and the drinking water did not exist, the cholera either did not spread or it extended itself only amongst the poor and dirty. All the early cases of cholera in London, in the autumn of 1848, following one in a seaman from Hamburgh, occurred amongst persons who obtained their water by dipping a pail into the Thames, or from St. Bride's pump,

which had a communication with the river by means of the Fleet ditch sewer. He believed that several diseases, including abdominal typhus and the plague, were communicated in the same way as cholera, and that ague was often caused by drinking the ditch-water of marshy places. He considered that the progress of cholera could be better stayed by sanitary measures than by quarantine regulations; but the sanitary measures should have a relation to the mode of communication of the disease, or they might be injurious instead of beneficial; the late epidemic of cholera having, he believed, being much aggravated in London, and especially in Hull, by presumed sanitary measures.

The reading of the paper occupied the time of the meeting until a quarter past ten: the discussion was, therefore, adjourned until the next ordinary meeting, when a paper "On the Use and Limits of Statistics, as applied to Epidemic Diseases," by Mr. Hunt, will be read.

BIRMINGHAM PATHOLOGICAL SOCIETY.

April 3rd, 1851.

MR. W. H. PARTRIDGE IN THE CHAIR.

Absorption of the Tissue of the Left Kidney, with dilatation of the Pelvis and Infundibula, probably from obstruction in the Ureter by pressure of the Sigmoid Flexure, the Kidneys being placed abnormally.—By Dr. Russell.

Henry Hunter, aged 44, married, a barber. I visited him first January 21st, 1851. He had been under Mr. Welch, as a dispensary patient, since January 8th. I have my imperfect notes of his—

History.—He has been ailing for ten years. For five years and a half he has been attended by Mr. Williams at various times. He has been subject to pain in the region of the loins, according to his own account for twelve years, but never has had dysuria, and to repeated attacks of severe and uncontrollable diarrhœa, sometimes with bloody stools, for four or five years. His present severe illness is of six months' duration, during which term he has suffered from severe lumbar and abdominal pain. His bowels were severely purged at the beginning of his illness, but have been confined through the greater part of it. His feet have swelled for four or five months. He has been subject to indigestion for some years. Some years ago he suffered from severe vomiting; for the space of two months he rejected every thing swallowed. This symptom has not returned till lately; for a long time, however, he has had trouble to keep his food down, and has swollen very much, at times, from flatulence. For the last three or four months he has been much troubled with prolapsus ani on going to stool. He continued to go about until the time when my attendance began; he then took to his bed. He has suffered great reverses, and has been much depressed thereby, and has had great anxiety. On my visiting him on the 21st of January I found him in bed; his chief complaint was of very severe diffused pain over the whole loins, and over the abdomen. He had œdema of the legs. He was a small spare man, of very nervous temperament. I could not detect any disease by careful examination, nor did he wear in his face any character of severe organic disease. He obtained no relief from the pain, which was still diffused over the loins and over the abdomen. The anasarca increased, and for a short time the scrotum filled with fluid. For the last month he was troubled with cough. Emaciation became very apparent only during the last three weeks of his life. The pain continued to the last. He died in the evening of March 22nd. The urine was free from albumen, and presented no peculiar microscopic appearance.

Sectio-cadaveris sixty hours after death.—Thorax: The left lung generally much engorged and firm, crepitated imperfectly; it contained several small abscesses, of recent formation, probably from the diseased condition of his blood. There were no tubercles. The pleura at the apex was thickened and white, like cartilage; there were no adhesions. Heart flabby. Aorta free from atheroma, but in the thoracic part, below the arch, the delicate lining membrane looked as if frayed, and separated very readily. *Abdomen:* The pyloric valve of the stomach was very considerably thickened, so as materially to diminish the aperture; the coats at the valve were a quarter of an inch thick, but the hypertrophy did not extend further. The mucous membrane of the stomach, near the valve, was dark coloured, from enlargement of its minute vessels. The duodenum was much contracted. We opened the entire length of intestines, to below the sigmoid flexure, but found no ulcer, no cicatrix, nor enlarged follicles, except two or three oval ulcers in the cœcum—a curious fact in connection with the prolonged diarrhœa in his history. The lower portion of the ilium was greatly thinned by atrophy of its coats, and the small vessels were enlarged, and loaded with blood. Liver large, its vertical diameter much increased; it was very homogeneous in texture, and of a uniform brownish yellow colour; its cells were greatly loaded with fat. Pancreas healthy. Spleen looked healthy, but was not opened. The kidneys were situated more forwards than natural, their lower extremity being united upon the spine, just above the promontory; the proper tissue of the left was partially absorbed, a series of large cavities having been formed, chiefly at the expense of the pyramids. These cavities were placed around the circumference of the organ; they were lined by a smooth dense membrane, apparently derived from that of the pelvis of the kidney, with which most of them freely communicated; they were separated by varying strips of renal tissue, almost all derived from the cortical portion, for only a a few fragments of pyramids remained, some of them approached very closely to the exterior. The right kidney was free from cavities, its cortical portion seemed disproportionably increased. The ureters from both kidneys were healthy; they passed forwards at once, descending over the front of the respective kidneys, and were quite free from dilatation. Bladder healthy.

By the Microscope.—The epithelial cells of the tubules

were found completely disintegrated, and to an equal extent in both kidneys; the tubules were filled with amorphous matter, evidently the debris of the celis, which in some tubules was washed out, leaving the proper membrane of the tubules, and the structure of the kidney disclosed.

Dr. Russell stated that he had submitted the details of this curious case, with the specimens, to his friend Dr. George Johnson, of King's College, London. Dr. Johnson confirmed his statement of the microscopic appearances, and attributed the cavities in the kidney to distension of the pelvis, from obstruction to the egress of the ureter; he supposed that the obstruction was caused by the pressure of the sigmoid flexure of the colon upon the left ureter, as it passed over the front of the kidney, as it was evident, from the undilated state of that tube, that the obstacle had existed at its very commencement. "The condition of the kidney and epithelium," he says, "is such as I have commonly seen in the kidney of persons beyond the middle period of life, who have been intemperate, or half starved, or both." This condition, he adds, "would not be associated with albuminuria, nor other symptoms of deficient excretion." He believed that the state of the kidneys had no share in killing the patient, and doubted if the slow process of dilatation would be associated with much pain. The condition of the renal cells, and the abscesses in the lungs, both prove the blood to have been in a morbid condition, and probably that was more concerned in producing the latter symptoms, and the fatal termination.

SOUTH-WESTERN BRANCH.

In our account of the meeting of this branch, in our last number, the following new members of the Council were omitted:—Dr. Miller, Exeter; Dr. Shapter, Exeter; Mr. Pridham, Exeter; Dr. Field, Torquay; Mr. Ward, Bodmin; in the room of those who retire, according to rule, viz.:—Dr. Budd, Exeter; Mr. Price, Lympstone; Mr. Woodward, Honiton; Mr. Symes, Axminster.

Foreign Department.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DES SCIENCES.

M. Colin, of Alfort, has published his experiments on the "*Pancreatic Juice in the larger classes of Ruminants*," instituted with the intent of observing whether the effect is the same as has been ascertained in the case of the carnivora. His conclusions are:—

1. That the secretion is intermittent, being at one time abundant, at another almost absent.

2. That the greatest abundance is secreted towards the close of the act of rumination.

3. It has the power of emulsionizing the oils, as in the case of carnivorous animals.

ACADEMIE DE MEDECINE.

M. Berard reported at some length several communications from M. Duchenne, of Boulogne, on the "*Study of Muscular Action by means of Local Galvanism.*" M. Duchenne's proceeding is entirely new; instead of forcing the needles into the muscles, he uses moist excitors applied to the skin, as a means of transmitting the current to the muscles to be experimented upon. By the same treatment it is possible to ascertain the exact action of the various muscles, and to elicit certain phenomena of great interest.

M. Gimelle reported on an essay by M. Hutin, on the "*Importance of Extracting all Splinters and Foreign Bodies in the Treatment of Gun-shot Wounds.*" The author cited a great number of cases observed by him in the Hospital for Invalid Soldiers, in which the most serious consequences had resulted from allowing splinters to remain in the flesh. He would advise every effort to be made, short of compromising life, for the purpose of extracting these foreign bodies. M. Velpeau, in discussing the paper, exhibited the necessity of greater caution than the author suggested, and pointed out that more danger would, in many cases, accrue, from the attempt to remove splinters than from leaving them. The same sentiments were expressed even more strongly by M. Malgaigne, while M. Hutin's practice was defended by M. Gimelle.

M. Cazeaux has been named a member of the Obstetrical Section. The opposing candidates were,—M. Chailly-Honorè, M. Depaul, and M. Devilliers.

GERMANY.

Germany has sustained a loss in the person of Nægele, the celebrated accoucheur. He was born at Dusseldorf in 1777, and was early destined for the medical profession. After a preliminary education in a Jesuit college, Nægele commenced the study of medicine in his native city, and became prosector of anatomy at the Medical School. In subsequent years he made a scientific tour, and in 1810 settled at Heidelburg, where he became Professor, and soon after President of the "Institute d'Accouchements" of the Grand Duchy of Baden. His principal writings are:—"*Experimental Researches on the Diseases of Females*," 1812; and on the "*Obliquely Contracted Pelvis*," 1839, besides other works and numerous contributions to periodical literature.

General Retrospect.

PRACTICAL MEDICINE AND PATHOLOGY.

Aphonia and Cough from Prolonged Uvula.—By Dr. Ready, (U.S.)

The case of a young lady is recorded who had been unable to speak above a whisper for over four years, during which period she suffered from incessant cough, which she said attacked her after exposure to cold. She had consulted many physicians without relief. Upon

examination of the fauces, Dr. R. found the uvula enlarged to an enormous size, about one inch in length, hanging over the rima glottidis, and all the adjoining parts inflamed and engorged with blood. "I immediately came to the conclusion," he says, "that the secret of the aphonia and coughing was an enlargement and prolongation of the uvula, and determined upon excision of the same, which I did, and in ten minutes after the operation she could speak as loud as any one in the room, and has continued to improve from day to day ever since, so much so that she can now sing a tune in as good style as she could before her attack. A slight coarseness of the voice, and inability to execute high notes in singing, is all the difficulty she experiences. It is a curious fact in this case that out of some half-dozen physicians who had before attended her, not one had ever examined her mouth and throat, and thus overlooked what would most certainly have relieved her years ago.—*St. Louis Medical Journal.*

[This is no uncommon cause of persistent cough. We are acquainted with a case of supposed hysterical cough, in which an eminent London physician has lost credit for want of taking the trouble to examine the fauces.—Ed. J.]

Phthisis Pulmonalis.

Dr. Speer advances the following propositions as embodying his views of the pathology of phthisis:—

1. The tubercular and scrofulous diathesis are identical.

2. Inflammation of the pulmonary substance is modified by this diathesis; its products being either scrofulous pus, scrofulous lymph, or tubercle.

3. In the great majority of instances the earliest phase of phthisical disease is local excitement of the air vesicles and smaller tubes.

4. The local excitement differs essentially from the analogous condition which exists as the commencement of sthenic inflammation, in its slow progress and difficulty of recognition.

5. That all the symptoms of phthisis are the result of scrofulous inflammation of the lungs.

6. That where this tubercular diathesis is very strongly marked, tubercle may be deposited under very trifling local irritation.

7. That the auscultatory signs of incipient phthisis may be divided into—1st. Those which occur in cases where the tubercle is thrown out simultaneously with, or subsequent to, the local excitement. 2nd. Those in which it is not deposited until actual inflammation of a specific character has set in.

Lastly. Incipient phthisis may present all its characteristic symptoms before any tubercular matter has been eliminated.—*Medical Gazette*, June 13.

SURGERY.

On the Position of the limb in Diseases of the Hip-joint.

Mr. Holmes Coote, makes the following observations on the difficulties attending the diagnosis of this affection:—There are but few surgeons who have not experienced occasional difficulty in forming an accurate opinion as to the character of the morbid changes which occur during life in chronic disease of the hip-joint. In the early stages there is frequently but little pain, and children so affected, especially amongst the poorer classes, are permitted to walk about and pursue their daily avocations, without notice being taken of their lameness, until at last a fall or some other accident excites more acute symptoms, and induces the parent to seek professional assistance. The surgeon finds the pelvis oblique; the affected limb apparently elongated, and slightly everted; he finds that in bending the thigh upon the trunk, the whole pelvis moves with the femur; pressure over the hip-joint excites, perhaps, little pain; there is flattening of the buttock, and the trochanter major appears more sunken than natural. The history accompanying such a case is often as follows:—The child was in perfect health, and able to run about until about a week or two ago, when, in consequence of an accident, it was thrown down upon the side. Upon being taken up, it was found to be lame and has been unable to walk ever since. The history of the case, and the position of the limb, might lead to the belief that the head of the bone was dislocated upon the thyroid foramen, especially amongst those who consider that inversion and not eversion of the foot, is the position assumed by the inferior extremity in the earlier stages of hip-disease. I propose offering a few remarks upon the position of the limb, granting that, as is commonly asserted, there may be inversion and not eversion; that there may exist a resemblance to dislocation on the dorsum ilii, or to dislocation on the thyroid foramen; but denying that such varieties can ever be referred to accident.

In the commencement of an inflammatory affection of the hip-joint, the thigh is bent upon the body; the whole limb is slightly everted and abducted; the anterior superior spinous process of the ileum of the affected side is either raised, when the limb appears to be shortened, and the sound hip more sunken than the opposite, or it is depressed or thrown forwards, when the whole limb appears elongated, the knee being bent, and the toes touching the ground a short distance in front of the toes of the sound limb.

The elevation or the depression of the anterior superior spinous process of the ilium of the affected side depends upon whether the patient happens to have been forced to follow his occupation during the early stages of the disease, or whether he has been in circumstances which allowed him to rest when in pain or uneasiness. The spine of the ilium is generally sunk and thrown forwards, and the limb apparently elongated; that position being the one in which the diseased joint will be easiest, the patient standing upright. But if he be forced to walk about, the pelvis becomes oblique in the opposite direction, the spine of the ilium is raised, and the limb is apparently shortened. The patient, throwing as much as possible of the weight of the body upon the sound side, limps upon the extremities of the toes of the affected limb, the foot being extended that its tip may just touch the ground.

The flexion, eversion, and abduction of the limb constitute the position into which it would be naturally thrown by the combined action of the powerful muscles which surround the hip-joint. The synovial membrane is inflamed and tender, and unfit to bear pressure; the patient, therefore, indistinctively endeavours to relax every muscle directly in contact with the joint. The psoas and iliacus, passing over the front of the synovial membrane and tightly pressing upon it where the limb is extended, flex and evert the thigh, the gluteus minimus will contribute to flex it; the pyriformis will abduct the limb; the gemelli and the two obturators, especially the obturator externus, will evert the limb. it is unscientific to refer the position of the limb to effusion of fluid into the synovial membrane; it is but rarely that we find the joint so distended, especially at the commencement of the disease, when eversion is the common symptom. It may be true, that if the joint be tightly distended by the artificial injection of fluid after death, the limb will assume the position above described. The attachments of the capsular ligament are in harmony with the sphere of action of the muscles which surround the joint. That the muscles which evert the limb may act with greater freedom, the fibrous capsule is unconnected with the posterior part of the neck of the femur; it forms there a ring not very unlike that which surrounds the head of the radius in the forearm. After a sudden fall, or a blow on the hip, the limb becomes at once everted, if the joint is bruised, long before sufficient time has passed for the capsule to become distended by fluid.

In course of time, as has been proved by innumerable *post-mortem* examinations, the disease produces thickening of the synovial membrane, absorption of the articular cartilage, and ulceration both of the head of the femur and of the acetabulum; the shortened neck of the femur slipping upwards and backwards in the enlarged acetabulum, approximates the fixed points of insertion of all those muscles which have everted the limb. They waste and become atrophied, being no longer in action, and the buttock appears much flatter than on the sound side. The gluteus medius and the adductor muscles then influence the osition of the limb, their power being increased by the absorption of the neck of the femur. We may therefore say that, in the second stage of the disease, the limb passes from abduction to adduction; from eversion to inversion. Still flexed it is drawn across the sound thigh, the toes pointing downwards, when the position somewhat resembles that of a limb in dislocation upon the dorsum ilii.—*Medical Times*, May 17, 1851.

MIDWIFERY.

Ovarian Cyst: Death from an unusual cause.—By Dr. Van Buren.

The patient, a widow, aged 29, first discovered a hard moveable tumour in the right iliac fossa five years since. At the time of her admission into the hospital (May 30th, 1850), the existence of an ovarian tumour was clearly ascertained. She was very subject to colicky pains in the bowels. The tumour was very moveable, and was thought a favourable instance for ovariotomy.

August 28th.—Was seized with symptoms of peritonitis, and was treated with calomel and opium and a blister.

On the 1st of September all evidence of peritonitis had disappeared, but the symptoms of a more alarming character supervened, such as pinched and sunken face and thready pulse. She sunk exhausted.

Post-mortem examination twelve hours after death.—The abdomen was opened by crucial incisions. The flaps thus made were found to be adherent, by their peritoneal surfaces, to the tumour, which was very dark in colour, almost black, and at points greenish. The peritoneum in contact with the tumour was stained of the same colour by imbibition. The omentum, small intestines, and colon, wherever in contact with the tumour were adherent to it, and stained of the same colour. These adhesions were torn through without difficulty, being evidently of recent deposition. There was no fluid in the cavity of the peritoneum, and no evidences of peritonitis except in contact with the tumour. On separating the tumour from its adhesions, which had thus fixed it in its position, it was found to be connected with the uterus by the right broad ligament, and, in fact, to consist of the right ovary. In the broad ligament, which was somewhat elongated, and the sole pedicle to the tumour, was a short very tight twist, which was found to have been produced by the revolution of the tumour upon its axis one and a half times. On the distal side of the twist a mass of very much distended (ovarian) veins were visible. Internally the tumour was deeply stained with blood, with which it was yet intensely congested; its structure was evidently fibrous, with irregular cavities throughout its substance (fibrous overgrowth of the ovary).

Dr. Van Buren attributes the peritonitis and enteritis to inflammation originally set up in the pedicle of the ovarian tumour, which by some accident had become twisted.—*New York Journal of Medicine*, March.

MEDICAL JURISPRUDENCE.

On a certain and constant Diagnostic between vital and post-mortem Burning, with some Directions for the due Investigation of this question.—Dr. Giuseppe Piretti.

Having considered the various tests already suggested by science for deciding whether combustion has taken place in the living or the dead body, the author adduces others which are fully established by the facts he brings forward. Accidental or criminal burning, produced in the living body, besides being distinguished from spontaneous combustion and from death by lightening by characters well known to science, may also be diagnosed from that which has taken place in the body after death, by various sufficiently evident external and internal marks. He details such characteristics, and among the external produced by burning in

the living body, he remarks the red lines on the skin surrounding the burns, and the blackness of the blood, which demonstrates a change effected in its normal condition by the heat. These lines, he observes, are not removed by the pressure of the finger. The changes he detailed could only, he states, take place under vital influence. He also describes the internal characters, which, according to him, consist in inflammatory and gangrenous spots scattered over the internal surfaces of the serous membranes, especially on those which cover the organs contained in the cavities. These phenomena, he adds, ought to be considered as quite characteristic of criminal or accidental burning, because they are never present where combustion has taken place in the dead body; and he asserts that, even if all the external signs enumerated by him be thought insufficient to establish the distinction, the internal inflammatory or gangrenous marks certainly cannot mislead; and that therefore he is entitled to conclude that the objections of those who hold these signs to be doubtful and insufficient to solve this important medico-legal question are untenable.—*Il Raccoglitore Medico di Fano*, 15th January, 1851, page 35.—Quoted in *Dublin Quarterly Journal*, May.

CHARTER OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I am directed to forward you the enclosed copy of proceedings, and to request you to be good enough to insert it in the next number of your journal.

I am, Sir,
Your obedient servant,
GEORGE BOWRING.

Manchester, July 2, 1851.

A meeting of members of the Royal College of Surgeons was held yesterday afternoon, at the Town Hall, "to take into consideration the present state of the charter of the College, previous to the introduction into Parliament of a bill for the regulation of the medical profession." The gentlemen present were Dr. Sinclair, Messrs. W. W. Beever, D. Noble, G. Southam, John Hatton, G. Bowring, Henry Winterbottom, J. M'Keand, Trafford Whitehead, John Walsh, R. H. M'Keand, G. V. Birks, W. Briggs, W. E. Manley, of Tyldesley; Fawsitt, of Oldham; Leah, of Gee Cross; and Bellot, of Stockport; &c., &c. Mr. Beever was called to the chair, and resolutions to the following effect were unanimously agreed to:—That the resolutions of the Royal College of Surgeons, passed on the 19th and 24th of March last, are of so just and conciliatory a character that they should be accepted, so far as surgeons are concerned, as the basis upon which a final settlement of the medical reform question should rest. That, as the resolution in question concede the proposals submitted to the Right Hon. Sir George Grey, Bart, in May, 1850, by a deputation of provincial physicians and surgeons, with the exception of the points relating to the payment of a fee, and the standing of members on admission to the fellowship, this meeting deems it right that a decision upon these two questions shall rest with Her Majesty's Government. That this meeting reiterates the condemnation of any measure of medical reform that provides for the establishment of what has been designated a college of general practitioners, &c. That a memorial, embodying the substance of the above resolution, and signed by the chairman on behalf of this meeting, be forwarded to Sir George Grey, Bart., with a request that he will proceed with the subject of medical legislation during the present Session of Parliament, and that the following be adopted as the memorial to be signed by the chairman:—

"To the Right Hon. Sir George Grey, Bart., Her Majesty's Principal Secretary of State for the Home Department.

"Sir,—The undersigned, as chairman of a public meeting held in the Town Hall, Manchester, of members of the Royal College of Surgeons of England, begs respectfully, on behalf of the same, to call your attention to the following circumstances:—Certain resolutions, adopted by the Council of the College in March last, are deemed by the members residing in Manchester and the immediate neighbourhood, to be of a character so just and conciliatory, that they may be accepted, so far as surgeons are concerned, as the basis upon which a final settlement of the vexed question of Medical Reform should rest. You will have noticed that, with the exception of two points, the resolutions in question concede the several demands submitted to you by a deputation of provincial physicians and surgeons, in May, 1850; these points, involving the payment of a fee on admission to the fellowship, and the standing rendering members eligible to it, the surgeons of this locality respectfully submit should be determined by yourself on behalf of Her Majesty's Government. And tendering to you, Sir, our grateful acknowledgements for the anxious consideration which you have given to this subject, we have once more to urge that, in any measure of medical legislation which you may introduce, all provision be excluded for a separate incorporation of general practitioners so called. Believing that the differences upon the subject of Medical Reform that have hitherto obstructed the several attempts at legislation, may now be satisfactorily accommodated, the undersigned, on behalf of those whom he represents, most respectfully prays you to introduce a bill for the better regulation of the medical profession, during the present Session of Parliament.

"Signed on behalf, &c., of the meeting.

"W. W. BEEVER, Chairman.

"Manchester, July 1, 1851."

The proceedings concluded with a vote of thanks to the Mayor, for his kindness in granting the use of a room for the purposes of the meeting; and to Mr. Beever, for the able manner in which he had presided.

Correspondence.

DR. HALE AND THE UNIVERSITY OF ST. ANDREW'S.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—On the principle of *audi alteram partem*, and as fellow sinner with my friend Dr. Hale, whose recent

"gross deception" you have so energetically exposed, permit me to offer a few remarks illustrative of my ideas on the subject.

The charge against Dr. Hale, as I understand it, is this:—That when he was examined at St. Andrew's touching his knowledge of the practice of physic, he answered the questions, not according to his own judgment, but in the way he imagined his examiners would best approve of.

But first, as regards the heading of the examination paper. If this was designed to prevent a believer in what is called Homœopathy from passing an examination, a gross act of dishonesty was attempted to be perpetrated by the University? On it certain powers have been conferred, to be exercised for a certain definite object. This object is, that candidates who are possessed of a sufficient amount of qualification and medical knowledge, shall be empowered to exercise it, in virtue of a diploma received from the University. If a candidate who possesses this amount of knowledge is refused a diploma, the University is guilty of an act of dishonesty towards the practitioner, and of deception on the public. His being possessed of a *greater* amount of knowledge than they require, that is to say, his having acquired a knowledge of the use of a number of remedies of which the examiners know nothing, cannot disqualify him. In all fairness and reason it ought to be left to *him* to decide whether he shall communicate this *extra* knowledge to his examiners. If he chooses to do so it is a work of supererogation. If a set of men can be found so blinded by prejudice to a sense of their duty, as to punish a man because he knows *all* that they do, and *something more*, any reasonable amount of "deception" is justifiable, when the object to be attained is a laudable and necessary one, and when, through their dishonesty, it cannot be obtained without it. If you were to be tried by a judge who always managed to obtain the conviction of every prisoner who had red hair, surely if you were so unfortunate as to be of the number, it would be a pardonable deception for you to dye your hair black.

As long as so great an uncertainty appertains to the practice of medicine, the "deception" practised by Dr. Hale, is more or less practised by every candidate for a diploma, who has any practical knowledge of his profession. Do you not yourself remember, Mr. Editor, when you were preparing for your examination at "the Hall," that it was again and again inculcated on you, that if Mr. A. asked you a particular question you were to answer it one way; whereas if Mr. B. asked you the same question, you were to answer it in another? Was it not the same at "the College?" And would you have imperiled yourself by departing one jot from the indicated track?

Suppose a disciple of Broussais were to be examined by a staunch Brunonian, (for even such still exist) is it reasonable to suppose that he would contend for all the dogmas of his master? Suppose a hoary-headed disciple of "Young Physic," whose long experience has taught him the dangers of the heroic practice, and that it is much more easy to do harm than good; for example, (*vide* Forbes' Review, vol. 22, p. 243,) suppose such an one to be examined by the dauntless hero who presides over the Edinburgh College of Physicians, fulminates anathemas against homœopathy, glories on slitting up the os uteri on the smallest provocation, leaves a sponge tent for days in the womb, physics *ad libitum*, what chance would he have, if, when asked how he would treat disease A., he should answer "do nothing;" disease B., "amuse the patient;" disease C., "give cold water;" disease D., "bread-crumb pills," &c. It would be manifestly impossible for any one so circumstanced ever to obtain a diploma; and such there are in our profession, who probably have been the examiners of the examiners. I might extend these examples to an indefinite length, but I spare you further details; I only ask which of these should cast the first stone at Dr. Hale?

In sooth, Mr. Editor, you are treading on dangerous ground. You are exposing the nakedness of your own kith and kin. You know as well as I do, that if you were ill, and were to consult on the same morning any six practitioners, no two of them would recommend the same treatment. You know that there is no such thing as an approximation to an uniform treatment of disease, and that if a dozen really thinking and practical men were to be examined by the same examiner, and were conscientiously to found their answers on their individual experience, and the examiner was to reward them according to his idea of their merits, no two of them would pass. Such a thing never has, and never will be done, as long as medicine remains in its present state. Ninety-nine candidates out of a hundred give a certain orthodox routine practice, which they have gathered either from authors or lecturers who, in practice, would probably be the first to repudiate their own teaching.

One word as regards homœopathy. The practitioners, in many instances, have based their conviction of its truth on large experience. There was a time when they were as sceptical as yourself. Have you, Sir, any really practical knowledge of the system you denounce? If so, for the benefit of the profession, and the confusion of the homœopaths, inform the world of it. Have you ever (as is the case with the humble individual who now addresses you) patiently persevered for months with experiments with the homœopathic medicines? If not, let me recommend you to set about it, or at all events to urge on your readers to undertake the task. I will give a prize of twenty guineas for the best series of experiments illustrative of the *failure* of the homœopathic medicines, if you will give a similar prize for the best series of successful cases; your readers would then be able to decide on facts, not on empty words. Of one thing you may be certain, that the believers in homœopathy laugh to scorn all the attempts at petty persecution and bitter invective founded on ignorance. If their system is true, you might as well attempt to fetter the waves with a thread, as to extinguish the smallest spark of truth which it contains. When their system is *proved* to be false, they, of all others, will most rejoice to aid you in its destruction.

I am, Sir, yours obediently,

GEORGE HILBERS,
M.D., UNIVERSITY OF ST. ANDREW'S, M.R.C.S.E., AND L.A.C.

19, South Bedford Street, Liverpool.
June 23, 1851.

MEDICAL BENEVOLENT FUND.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—That the present state of the profession is one of extraordinary depression and distress is well known to most of its members as well as to the Committee of the Benevolent Fund. The provincial practitioners especially, are suffering indirectly from the pressure of agricultural distress, and the practitioners of cities are not only too much crowded together to live, but the bone for which they are contending is too often carried off by the quack. I believe, however, that the public are but little aware of the sufferings of a class of men, who, perhaps, more than any others, shrink from the public gaze, when the hand of adversity is upon them. The design of these remarks is not to reiterate (in tones more feeble than his own) the claims which the worthy Treasurer of the Benevolent Fund has so frequently urged upon us, for in attempting this I might weaken the effect of his heart-stirring yet truthful eloquence, but to point out how much the profession at large *gains* by what it does for its depressed members. The public have much personal sympathy with medical men. It cannot be otherwise. Who can regard with indifference or scorn the hand that has delivered them from suffering, and rescued them in danger; the eye that has cheered them in distress; and the voice whose accents have inspired them with hope and confidence in the midst of alarm and trepidation? Yet, how often is the feeling confined to the individual. How seldom does it occur to the patient that the whole profession is employed by night and by day in the same blessed offices of healing, soothing, and saving from danger and from death. Like the clerical office, ours is one of sacredness and sanctity. It stands out from among the ordinary engagements of the world as something not merely professional, or commercial, or artistical, but dignified and unsecular; only one degree less noble than that of the minister of religion. Yet, from a singular perspicacity in the public mind, it will never esteem us rightly until we have learned rightly to esteem and care for each other. When we have fully learned our corporate duties and privileges, so that if one member suffers the whole body suffers with it—if one is offended all burn with indignation, then the world would be touched with a proper sympathy with the sufferings as well as the merits of the profession. To the world we have abounded with charity: to each other we have been cold, distant, unpitying. We have laboured to exterminate small-pox, to prevent the spread of epidemics, to promote the general health, all for the public good and to our own loss. Yet public men insult and scorn us. We have laboured gratuitously for the poor more than any other class of men: yet, who so bitter and brutal to us as Poor-law Commissioners and Guardians? And the reason of all this is we are not true to ourselves. Our public spirit is wasted on the ungrateful world at the expense of our brethren, and to the jeopardy of our position in society. Now, much of this would be corrected in ourselves, and much of the coarse feeling of the world towards us would be refined and softened, if we could only unite not by half-dozens, but *as a whole*, to anticipate and relieve the distress which may come most unexpectedly upon any one of us, and assuredly will come on very many of us. I therefore, plead for the destitute, not for their sakes alone, but because it is more blessed to give than to receive, and because the reflex influence of this brotherly love sheds a halo of honour and dignity throughout our ranks. And this is not all. The world properly refuses to help those who will not make an effort to help themselves. Our own benevolent efforts are not the single handed ministers of good which they appear to be. They are the germs of a goodly progeny. The benevolent Mr. Propert, (the Newnham, of London) in his noble undertaking to furnish the profession with an asylum for the destitute, and a collegiate education for their sons, has awakened, the interest of not only our gentry, but our nobles and prelates, who are cheerfully coming forward to plead so noble a cause; and it must needs be that the profession will rise in the esteem of such men in proportion as they witness its works of faith and labours of love, exercised in behalf of their own necessitous brethren. On this principle the still too much neglected Medical Benevolent Fund is not only a charitable fund, but is a fund of influence and power, for the benefit of the whole profession. If every member of the Association were to solicit from every wealthy patient an annual contribution to this fund, he would stand better in the eyes of that patient. He would by this act of charity and good-will be himself a gainer, even if the boon be refused. A man who begs importunately for a suffering brother may be repulsed, and counted as a bore; but, in spite of that, he will be held in involuntary respect. No man, however brutish, can wholly withstand the mollifying influence of sweet charity, doubly blessed. And it is impossible that several hundred members of our profession can be seen earnestly soliciting charity for their poorer brethren (it may be their opponents whom their own success has impoverished) without making an impression on the public mind highly favourable to the profession at large. The effort should be made discreetly and advisedly, and within proper bounds, yet not without zeal, constancy and perseverance.

The above sentences were penned previously to the meeting held at the Hanover Square Rooms on the 25th instant, in furtherance of Mr. Propert's noble scheme; but at that meeting a singular confirmation of the views above stated dropped from the lips of Lord Manvers, the Chairman, and was reiterated by other speakers. His Lordship most emphatically stated that it was not to be expected that this most needful and benevolent scheme would receive the support of the public unless the heads of the profession, and those members of the profession generally who were able to do so, came forward to the relief of the necessities of their own brethren. It was urged, that the clergy and other professional as well as trading bodies had their schools and their alms-houses, while the medical profession—the one of all others most exposed to want and distress, both by the nature of the occupation and the low scale of remuneration—had hitherto appeared indifferent to the claims of its poorer brethren; and yet that so

strong was the sense of benefit derived by the public from our needful offices that it could not be supposed that the public will refuse to help us. Indeed, no person present at that meeting, seeing a nobleman in the chair, three bishops, a baronet, other Members of Parliament, and several clergymen, on the platform, most of whom, with eloquence and energy, advocated the cause, could for a moment doubt that the public sympathy is strong for us, and that it is our own fault if we do not find it ready to help us when we are seen ready to help each other.

In alluding to Mr. Propert's scheme while professing to advocate the cause of the Medical Benevolent Fund, it may appear to some that there is danger lest I should distract the attention from the one by admitting the claims of the other. And in the very last number of the *Journal* there is evidently a fear implied, if not expressed, that the British Medical Fund Society may become the means of diminishing the subscriptions to the Benevolent Fund. Allow me to express a hope that this is a mistake. Dr. Forbes, who was on the platform at the meeting, most emphatically admitted that the British Medical Fund was in no danger from the Medical Benevolent College, the success of which he most heartily desired. Clergymen always find it more easy to procure subscriptions from their parishioners to half a dozen charitable objects than to one alone. The members of the Association who are really prosperous, and on whom ought chiefly to depend the success of the fund, only want to be brought into the *habit* of considering the poor and needy, and to feel that in that habit there is really and truly a blessing for them, and then there will be no danger of their pleading an excuse. Excuses will be found by those only who, being ignorant of the blessedness of giving, are determined not to give. But who is there among us who may not soon be deprived of the privilege of giving, and placed among the destitute and the distressed? A short time since a well-known member of the Association was in happy and prosperous circumstances, and had every prospect of providing for his family, but suddenly, poverty, like an armed man, has come upon him. The hand of affliction has touched him, and his prospects are now gloomy and desolate. He is one among the many whose history one of the speakers at the meeting above alluded to, graphically and touchingly summed up in these words:—"They do not retire from practice, they do not die, but they *disappear*." Poverty spreads her dark mantle over their path, and they are *seen* no more. They cannot dig; to beg they are ashamed. The Medical Benevolent Fund finds them bread. The Medical Benevolent College proposes to find them shelter. And both of these institutions are necessary. Nor can there be any reasonable doubt that they will help to support each other, and that the man who has willingly and cheerfully spared his annual guinea for the one, will find some method of self-denial which will enable him every twelve months to save a guinea for the other.

PHILALETHES.

THE BENEVOLENT AND BRITISH MEDICAL FUNDS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I did not think to have encumbered the pages of your valuable periodical with any observations respecting the "British Medical Fund," as I trusted by this time its merits would have been appreciated, and its principles understood, so as to have rendered advocacy unnecessary.

Your own editorial remarks, with the letter from Mr. Newnham, have induced me to say a few words, not, indeed, in the way of reply, but rather as explanatory on some points which both he and you have omitted.

I stand in a peculiar relation to this "Fund"—I will not say its founder, but as the projector of an institution out of which this Society has arisen. I trust, therefore, my observations will not be thought intrusive.

You may remember that, in 1845, at the annual meeting at Sheffield, I brought forth a proposition for establishing "A General Medical Annuity Fund," on co-operating principles. I never thought for a moment of disturbing, or superseding the "Benevolent Fund," already established—indeed I am convinced it never would have done so—on the contrary, my convictions are, it would have strengthened it. Others thought differently: not at the time, for, mark you, there was not a dissenting voice at Sheffield; but, subsequently, when I became involved in the affair too deeply to retrace my steps, a negative was passed upon my project at Norwich, and the Institution, which I had cherished so carefully for twelve months, was thus deprived of a home. It, however, obtained a location, for it became a "citizen of the world," or rather "a citizen of the three kingdoms." From its ashes, phœnix-like, has sprung the "British Medical Fund." Now, what injury can this Institution do your Benevolent Fund?" My belief is, the majority of its members have no connection with your Association; and I am convinced that those who are members of it, will not withhold their contributions to the noble charity so ably advocated by Mr. Newnham, a gentleman for whom I entertain the highest esteem, and to whose zeal and Christian philanthropy I wish to pay that homage and respect so eminently his due.

I certainly should never have stirred in this matter if the "Benevolent Fund" of the Association had come up to my notions of *permanent relief* to the sick, the aged, the widow, and the orphan.

As a *charitable* Institution it always had my warmest approval and support; and had I not latterly drawn so much upon my own resources in furthering my own project, it would have been my delight to have given it more substantial evidence of my good feeling than mere approval. As it is, it has my mite, and will have, while I have health and means. Still, the profession stands in need of something beyond *charity*—nay, it is not well that any class of men should look to such a source for help in time of need. There is a nobility of soul, which all men admire, in refusing unmerited gifts. If it be good to give, there is, nevertheless, ignominy in receiving; more particularly when

men might, by prudential combination, avert the necessity of it.

I do not intend to speak of "The British Medical Fund" as an insurance society, or to say whether the *scale* of payments are too high or too low; one thing I do know, that the calculations were made by Mr. Neison, whose reputation as an actuary, and his long connection with all the details of "Insurance" business, seems to put mere speculation out of the question. If I except myself too, I can say that the directors of this institution are gentlemen whose very names are a guarantee of safety; and I know full well how hard they have laboured, and how anxious they have been to render the Society as perfect as any human institution can be. The great feature of this institution to which I should wish to call especial attention at this moment, is that branch of it called the "sickness fund," the value of which seems to have escaped your Editorial notice. Here is a provision to meet the casualties of accident or illness—whether their consequences be temporary or permanent—to find support while the individual victim to either, is prevented from following his avocation. A provision, let me say, never yet attempted by the profession, and yet of all others, one would think the most needful; for what other calling under the sun is so liable as our own to such casualties. The darkness of night, and the confliction of elements keep not the medical man from the exercise of his duty. Nor will plague or pestilence hinder him from entering into the midst of its concentrated poison. I do not wish to be severe, but I feel bound to say that the non-establishment of an institution of this kind amongst us, is a blot and a stain which I care not how soon is rubbed out.

I can look around me and see the mechanic, the artizan,—nay, the common labourer, associating together, and out of their little earnings contributing something to form a fund for this worthy end. I can see buildings rising up as receptacles for worn out tradesmen—homes, wherein they can lie down and be at peace when their sun of life is setting. But with us, there is no such blessed haven. The practitioner in medicine and surgery, after the buffettings of his ill-paid profession—when worn by poverty, disease, or the creeping infirmities of age, is to be cast aside as a piece of lumber, to rot in his destitution and wretchedness, unless, forsooth, helped by the hand of charity. Oh! ye who have hearts in your bosoms, blush for such a fact as this, for in very truth my blood tingles as I write. Sir, I have very recently witnessed an example of this kind, and an example which I shall never forget.

A gentleman, whom I once knew, in the vigour of health and intelligence, a man above the ordinary, with fine feeling and noble aspirations, and with unsullied character. Paralysis at the age of 44 seized its victim, and prostrated both body and mind. A wife and eight children were dependent upon this poor man's exertions, but his powers are *nil*. He lies a mournful and melancholy picture, which makes the heart bleed to look upon.

Where can these innocent and helpless creatures look for bread? To a Provident Society? Alas! no. Such a society has no existence in the profession to which he belongs. Had he been a tinker, or a tailor, a blacksmith, or even a chimney sweep, there would have been no lack—there would have been help; and the sorrow of spirit for temporal wants, would not have been added to the pains of physical suffering.

I call upon the profession to think seriously of this particular branch of the "British Medical Fund," and to aid it by every exertion in their power. It matters not through what channel relief flows, so that it comes; yet, to honourable minds, the gifts of charity are painful; it is noble to be self-reliant, and by proper combination all men may be so. It is folly to express fear, or to cavil at this institution or that; the true aphorism —"let every tub stand on its own bottom," is true in institutions as well as tubs. The Benevolent Fund of the Association will stand and do its measure of good while charity remains; but charity, like mercy, "is not strained"—indeed, it cannot be forced, and even if it could, I should never value the gift. The question with the profession is—What is the best thing which can be done to meet the difficulties by which we are surrounded? For my own part, I am so little wedded to any project which I may have advocated, that I would strangle any institution of my own to make way for a better. Our main object is combination; our aim should be—the union of intelligence, and our support should be given to that plan, which in its end and issue is likely to impart the greatest good. How many valuable institutions have been frittered away by idle and useless cavilings—by denouncing as impossible that which only wanted energy and tact to prove its practicability.

Let us fix upon a principle which, in its ultimate development, will answer the end in view, and come to it with a determination to work it out, and, my word for it, the thing will be done. But if people are to pull down the bricks of a building as fast as they are laid on, how on earth is the superstructure to be raised? The Crystal Palace, that mighty evidence of human ingenuity and skill, would have exhibited a poor spectacle if every disbeliever in its final accomplishment had been suffered to throw stones at it. It stands now a monument of what combined talent can do—and so will the "British Medical Fund" if it be equally fairly treated.

In conclusion, let me say, I admire the "Benevolent Fund" of the Association, because it is *benevolent;* and although its powers are limited, it is, nevertheless, diffusive, and its gifts come as holy blessings. I admire the objects of the "British Medical Fund," because they are strictly and essentially *prudential.* This institution tells men in their prosperity to lay by a little, that when prosperous no longer they may not want. Like the sun, it absorbs in minute proportions those elements which, when duly gathered together, will return and fructify wherever they fall. Between the "Benevolent Fund" and the "British Medical Fund" there is scarcely an analogy. The former comes with its benign and Christian spirit, pouring oil and gladness upon sorrowing hearts, who have no refuge. The latter is itself the REFUGE; and if there be reproach in eating the bread of charity, there is no reproach here, as it is a just and legal right.

I am, Sir, your faithful and obliged Servant,

EDWD. DANIELL.

Newport Pagnell, June 26, 1851.

[We have with some difficulty found room for the above letter, but cannot find space for any remarks upon it; we hope to return to the subject in our next numb .—Ed J.]

Medical Intelligence.

TESTIMONIAL TO DR. LAYCOCK, OF YORK.

A handsome silver tea service has been presented to Dr. Thomas Laycock, of York, by the Associated Licentiates Extra Urbem of the College of Physicians, with the following inscription :—

"Presented to Thomas Laycock, M.D., Physician to the York Dispensary, Lecturer on the Practice of Medicine in the York Medical School, &c. &c., by his friends, the Associated Licentiates Extra Urbem of the Royal College of Physicians of London, in testimony of their very cordial esteem and regard, and in gratitude for the ability, energy, and zeal with which he has maintained their rights and interests.—Anno Domini, 1851."

The Committee of the Association comprises the following physicians :—J. Davies, M.D., Physician to the Hertford Infirmary, &c. &c. ; J. Birt Davies, M.D., Physician to the Queen's Hospital, and Lecturer on Forensic Medicine in Queen's College, Birmingham ; S. Hitch, M.D., F.L.S. &c., Sandywell Park, Cheltenham ; H. Johnson, M.D., Senior Physician to the Salop Infirmary, Shrewsbury ; T. Laycock, M.D., Physician to the York Dispensary, and Lecturer on Medicine at the York Medical School (Hon. Sec.) ; J. Thurnam, M.D., Medical Supintendent, Wilts County Asylum (Hon. Treasurer).

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Friday, the 27th ultimo :—William George Bacot, St. John's Wood ; Edmund Chapman, Tooting, Surrey ; Thomas Russell Johnson, York ; Robert Bohun Kidd, Norwich ; David Thomas Morris, Carmarthen ; John Pearson Nash, Calcutta ; Charles Thomas Pearce, Northampton ; Charles Joseph White, Portsmouth, Hants ; George Whitley, Durham ; Jacob Williams, Hon. East India Company's service ; John Williams, Pontypool, Monmouthshire.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, June 19th :—James Andrews, Pershore, Worcestershire ; Essex Bowen, Llwyn Glair, Pembrokeshire ; John Horton Broxholm, Sunbury, Middlesex ; John Dale, jun., Yarm, Yorkshire ; John Norton, Cowfold, Sussex ; George Edward Webster, Cambridge.

Gentlemen admitted on Thursday, the 26th ult. :—Alfred Horsley Bossy, London ; William Taylor Colby, New Malton, Yorkshire ; Henry William Hubbard, Bury St. Edmund's ; Octavius Henry Jennings, Colefield, Gloucestershire ; William Phillips Kirkman, Melton, near Woodbridge, Suffolk ; Robert Toulmin Leeming, Leeds ; Edward Charles Lewis, Richmond, Surrey ; Frederick Pratt, Swinbridge.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted members on Wednesday, June 25th :—Dr. Hooper, Grove Hill, Camberwell ; Dr. Sweeting, Abbotsbury, Dorset.

The following were also admitted Extra-Licentiates :—Dr. Sladen Davis, Fillongley, Coventry ; Dr. Jones, late of St. Leonard's-on-Sea ; Dr. Wilson, Whitby, York.

OBITURAY.

On the 23rd ultimo, at Sidmouth, Sir George Smith Gibbes, M.D., F.R.S. The deceased was a Fellow of the Royal College of Physicians, and was for many years Physician Extraordinary to Queen Charlotte, during whose reign he was knighted. He was also for a lengthened period a practitioner at Bath.

BOOKS RECEIVED FOR REVIEW.

On Gout : its History, Causes, and Cure. By W. Gairdner, M.D. Second edition. London : John Churchill, 1851. pp. 300.

Hand-Book of Natural Philosophy and Astronomy. By Dr. Lardner, D.C.L. London : Taylor, Walton, and Maberly, 1851. pp. 819.

Familiar letters on Chemistry. By Justus Von Liebig. Third Edition. London : Taylor, Walton, and Maberly, 1851. pp. 530.

On Diseases of the Mucous Membrane of the Throat, and their Treatment by Topical Medication. By W. R. Wagstaff, M.A., M.D. London ; John Churchill, 1851. pp. 183.

A Compendium of Materia Medica and Pharmacy. By J. Hunter Lane, M.D., F.L.S., F.S.S.A. Second edition. London : J. Churchill, 1851. pp. 310.

The Laws of Health. By Lionel J. Beale, M.R.C.S. London : J. Churchill, 1851. pp. 306.

Miss Martineau and her Master. By J. Stevenson Bushnan, M.D. London : J. Churchill, 1851. pp. 173.

The Wisdom and Beneficence of the Almighty, as Displayed in the Sense of Vision. By T. Wharton Jones, F.R.S., &c. London : J. Churchill, 1851. pp. 135.

Sunning Hill Wells. By Henry Holmes, M.D., &c. London : H. Renshaw, 1851. pp. 103.

The American Journal of the Medical Sciences—April, 1851.

A few Remarks on the Use of Impure Gold for Dental Purposes. By W. Imrie, Surgeon-Dentist. London : J. Churchill, 1851. pp. 11. Pamphlet.

An Inquiry on the Subject of Vaccination. By Benjamin Ridge, M.D., M.R.C.S.E., &c. London : J. Churchill, 1851. pp. 31. Pamphlet.

Report and Papers of Suggestions on the Proposed Gathering Grounds for the Supply of the Metropolis from the Soft Water Springs of the Surrey Sands, addressed to the General Board of Health. By the Hon. Wm. Napier.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

SHROPSHIRE BRANCH.

The Shropshire Branch of the Provincial Medical and Surgical Association will meet at Hay Gate, (one mile from Wellington Station,) on Tuesday, July 15th, 1851. After the meeting the members and their friends will dine together at the above inn at half-past three o'clock. Gentlemen who intend to honour them with their presence are requested to give notice to the President, or Mr. Taylor, Hay Gate, as early as possible, as dinner will be provided for those only whose intention is thus signified.

R. THURSFIELD, President.

TO CORRESPONDENTS.

Communications have been received from Mr. Colthurst, Mr. Moore, Dr. Symonds, Dr. Hughes, Mr. Humphry, Mr. Beales, Mr. Newnham, Dr. Nelson, Dr. Kingdon, Mr. Jeaffreson, Mr. Pritchard, Mr. Parker, and Mr. Thompson.

Inquirer.—We cannot undertake to settle the dispute on such a statement as that sent to us. It is too nice a distinction to attempt to draw without seeing the case. We can of course form an opinion, but we should not like to act upon it, especially as both parties do not seek the arbitration.

ORTHODOX MEDICINE;

AN ADDRESS,

DELIVERED AT THE ANNUAL MEETING OF THE BATH AND BRISTOL BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

By JOHN ADDINGTON SYMONDS, M.D.,
President for the Year.

On occasions such as the present, when the practitioners of our art are brought together at regularly recurring periods, one is naturally led to view the present in relation to the afore and after time. I will not attempt to compare the present condition of our Branch Association with the past or to speculate on its future progress, though in considering it in both these aspects we might truly take up a cheerful and gratulatory tone; for it has stood the trial of time, it has shown that its strength has not depended on the novelty of its interest; and the losses which it has in the course of chance and time suffered by the death or removal of members have been filled up by the steady influx of new recruits. Nor is it too much to say, that there has been an obvious advance in our prosperity during the last few years; nor will it be thought to involve anything like invidious comparison, or to present anything more than the simply true and just view of the case, if I remark that this success has been mainly attributable to the intelligent and strenuous exertions of the gentlemen who have been so kind as to undertake the onerous offices of secretaries.

From the state of our Association I will venture to pass to a far wider field, and to offer you a very few observations on topics which I trust will not be considered inappropriate to such a meeting as the present.

In the arduous and absorbing pursuits of medical life, the practitioner has generally enough to do in meeting the emergencies of the day and the hour. He toils on anxiously bearing in mind that golden injunction, "Oh! man, know thou thy work, and do it." He has scarcely any breathing time for "looking before and after." On, on he must fag; the wheel of events which he at once treads upon, and helps to keep in motion, will still revolve, and he must not lose his footing while he is speculating and philosophizing. He is therefore apt to forget or overlook the changes which have been going on about him, and in the very scene of his exertions. But it would be good for him now and then to pause and look around; for he would see much to encourage and cheer, and something to incite him to still greater exertions in the cause of science and humanity. Let me, then, on this occasion, invite you to join me in a moment's survey of that part of the world and its affairs in which we, as practitioners, are more immediately interested. And, first, let us glance at the state of our profession as a profession: and here, I think, there is little to be seen but what prompts us to mutual congratulation. It cannot be doubted that it is daily increasing in knowledge and wisdom; and that the proofs of this increase are to be seen in the attainments and character of its members generally, and more especially in the improved and improving education of those who are entering it. How that education differs from what was pursued not many years ago, in the range of its scientific requirements, I need not point out to you, but I cannot help noticing particularly the great change for the better in the most important department of all—I mean the practical instruction. "Walking the hospitals," as the old-fashioned phrase went, was often only lounging through them, and the only professional topic of interest was the last or the next astounding capital operation. But all this is changed, and through the talent, zeal and fidelity of the clinical teachers, both in medicine and in surgery, our young friends come from their hospital perambulations really enlightened as to the proper mode of dealing with those ordinary cases, the management of which will be the main occupation of their lives.

It has been the custom at the annual meeting of the Parent Association to survey the accessions to our professional knowledge made during each foregoing year. Could a digest of those reports be drawn up from the commencement of the Association, nearly twenty years ago, and a comparison drawn between the amount of information gained during that period, and the previous two decades, I cannot doubt that the advantage would appear decidedly in our own era. It seems to me that the great events between 1810 and 1820 were the publication of Laennec's immortal "Treatise on Auscultation," and of Sir Charles Bell's Researches on the Nerves of Sensation and Motion, and that between 1820 and 1830, the great achievements were in the field of pathological anatomy, and of transcendental or philosophical anatomy. The former of these certainly reached its culminating point during this period, and not very much in the way of discovery after that time was left for the mere scalpel of the necroscopist. It is of course out of the question for me to recite even in the most summary way, the history of our science and art since 1830. It will be enough to hint at a few broad facts that will speak for themselves.

In the department of anatomy we point to that unravelling of the ultimate texture of living structure technically called histology, under the help of the microscope, including, as it does, that wide-embracing idea of cell-growth, which has now become so familiar to us. In physiology I need only advert to the improvement of our notions respecting secretion, and nutrition, and generation, by the combined instruction of comparative anatomy, microscopy, and chemical research. A prominent place must ever be awarded to the collateral researches of Prout, and Mulder, and Liebig, and the other chemists who have devoted themselves to the analysis of organic substances: for what was organic chemistry before the period which we are now cursorily reviewing? The modern physiology of the nervous system, though dating its birth from the discovery of Sir C. Bell, may be said to have attained the most important amount of its present growth and development within this period. It matters but little

to the world how much had been hinted or sketched out in our department by Prochaska, or whether recent and ingenious observers have been too jealous as to the originality and value of their researches. It is enough for us to look at such a report of the physiology of the nervous system as was drawn up for the British Association by Dr. Henry, in 1832 or 1833; and to compare the knowledge at that time respecting the functions of the spinal cord, the cerebellum, the corpora quadrigemina, the thalami optici, the corpora striata, and the cerebral hemispheres or ganglia, with that which is now current amongst us, and to perceive how much we have learned from Dr. Marshall Hall, Mr. Newport, Dr. Carpenter, Dr. Todd, and Mr. Solly.

In pathology there are certain ideas to which we have become so habituated, and which have so grown with our growth, that we are unconscious of, or have forgotten, the recent date of their origin. Such is the humoralism of the present time; a formula of which medical thought cannot now divest itself. It is true that the dawn of this idea may be observed a little anteriorly to the time we are surveying. The "Anatomie Pathologique" of Andral, (in my humble judgment one of the most influential works of our century,) gave the first, though faint, expression to our modern humoral pathology, and it was published in 1829. Glance at your present notions of fevers, of puerperal sequelæ, of erysipelas, of certain cerebral affections in connection with the pathology of the blood and the secretions, and including that fertile subject of toxæmia, which has only partially yielded as much as it is capable of affording, and consider how little had been contributed to your knowledge of the subject before the time I speak of. And here I cannot but notice one of the most important pathological discoveries of our age—that renal malady, which, as Englishmen, we should be proud to designate as *Bright's disease*; for, setting apart the value of the discovery in connection with dropsy and albuminuria, I confidently ask whether the fellow to it in importance can be pointed out, when we consider the researches which have grown out of it, and which have not only enlightened the whole pathology of the kidneys, but have given an impulse to the study of secretory disorders in general, and have been most influential in drawing attention to what I have already hinted at—the contamination of the blood by matters which have failed to be eliminated.

For us, the representatives of orthodoxy, it would be enough to hint at improvements in pathology, being assured that there would be therapeutical deductions of less or more value. But, apart from those improvements in our *art* which have sprung from the improvements in our *science*, in certain special diseases, have we not in our general practice learned to be more wisely bold and more wisely timid? Have we not learned in certain diseases to stand aloof, and, instead of revolutionizing the processes of nature, to interpose only with the view of abetting the sanative, and restraining the destructive, tendencies! Have we not learned to spare the lancet in those cases in which the brain has suffered a local injury, or in which its functions have been less disordered by hydraulic causes than by the poisons which the blood has carried to the organ, whether it has derived them from some taint in the body itself, or from some outward formes? The depurative treatment of fevers, and our attempts, though often unsuccessful, at correcting the faults in the blood in these diseases, are all in the right direction. But I think that we may indicate the management of chronic disease in general as most surely marking the advancement of our therapeutics. It is true that a great change is observable in the treatment of acute diseases. When and where do we witness that terrible blood-shedding which was once so familiar to us, and to which we were once so callous? Why have so many lancets become rusty? What have been the scouring ideas that have purged our officinæ of so much of their perilous stuff? This change of practice has, it seems to us, had more than one cause:—1stly, we have learned that the abstraction of blood, even in the purest and most sthenic phlegmasiæ, cannot summarily eject the disease; it can but so qualify the blood, and so moderate the *vis a tergo*, and so alter the capillary circulation, and so influence the secretory actions, and so modify the neurotic element of what, however simple, is still a composite malady, as to place the suffering organs in a better train for the resumption of their natural state. I need not say that I do not here allude to cases of mere local hyperæmia, in which the curative influence of bleeding is more direct. 2ndly, we have learned to use other antiphlogistic remedies more freely, and yet discriminatingly, more especially opium, mercury, and antimony, and also to wait more patiently for spontaneous improvement. But, 3rdly, there has been a change in the type of that which we have to deal with. Unless our perceptive faculties have changed, we do not now, or at least very rarely, meet with those stalwart menacing inflammations which used to put the practitioner upon his mettle, and provoke him to those sanguinary onslaughts in which alone seemed to be safety, either for his patient's life, or for his own reputation as a skilful and determined practitioner. We cannot have almost suddenly grown so very wise as to be able to do without measures approaching to the old severities. Our fathers,—nay, our former selves, could not have been so very blind, and so very rash, as to have quite mistaken the characters of the cases and their exigencies. Why had their active practice superseded the expectant method of the end of the last century? Why was the practitioner, whose lancet was not always between his finger and thumb,—why was he thought feeble and timid, and belonging to the same class as the aged members of the other sex? We have more lights in the present day, but there is no reason to think that our natural vision is so vastly more penetrating. Such inflammatory cases as have been described in our medical classics, and have been witnessed by ourselves, and which now are *raræ aves*, were, I cannot doubt, for a cycle of years, common and every day cases. The epidemical constitution of the years has changed, and practice has

changed with it. Would wary, thoughtful, acute observers of the phenomena of disease and the effects of remedies, such as were our fathers, (however imperfect may have been their pathology,) would they have continued to bleed and purge in continued fever, in scarlatina and measles, if such practice had been as uniformly fatal as we believe it would be in these diseases in the present day? Could Dr. Armstrong, with all his eloquence and enthusiasm, have commanded a hearing, unless fevers had been for years more phlogistic than they now are, and than they were in the latter part of his career? I think not. And it is not beyond the possibilities that we may some day have to return towards some of the old modes of procedure, though there is little reason for apprehending anything approaching to the Sangradoism which we can remember, and of which the most remote of the recent apostles was M. Bouillaud.

But while bearing in mind this change of character in acute diseases, we must allow that our depletory practice has been greatly mitigated, if not abolished, in the treatment of chronic maladies. The lancet no longer spurs the downward course of tuberculous cases. The timorous dyspeptic may tell of his headache without fear of the cold steel that is to rescue him from apoplexy or meningitis; and he will confess to a numbness or a vertigo without expecting that cupping-glasses and scarification will inevitably follow, or a threat of being doomed to paralysis. But while we can thus number up proofs of caution and forbearance in our modern practice, of a due respect for the *vis medicatrix*, there is no lack of instances of bold and courageous interference with the *vis vitiatrix*. And perhaps they are chiefly to be sought in the annals of surgery and of obstetric medicine. But take one example as *instar omnium*, the administration of æther or chloroform, whether for medical or surgical purposes. There is in this practice, whatsoever else there may be, a noble boldness, I had almost said a divine audacity. This practice, the offspring of our own immediate time, may compare with the most splendid triumphs of human art. I envy not the sentiments or imagination, or rather the want of them, in him who can witness it without emotion;—who can see the temporary annulling of all that distinguishes man as a feeling, moving, thinking, speaking being;—who can see quivering flesh, and tender nerve, and tough fibre, pierced and severed and crushed and torn without suffering, and not feel a glow of enthusiastic admiration for the wise and happy discoverer of this wonderful agency—a throb of exultation at so beneficent a product of human skill, mingled with a feeling of gratitude to Him who had put it into the mind of man to devise such help for his suffering brother.

Did we require any further proof of the advancement of our science, we might find it in the prominence now given to all questions of hygiène, whether with reference to the prevention of disease and the preservation of health in the individual, or to the sanitary condition of the community. But enough of this theme.

I have now to make a few remarks on the state of public opinion in reference to our art. At first sight we might presume that the same considerations which have afforded *us* subjects for mutual encouragement and congratulation would also weigh with the laity in some degree, and augment their confidence in our ability to yield them succour. And with the more thoughtful, and well-informed, and sensible, I believe this is actually the case. But, alas! the thoughtful, and the well-informed, and the sensible, do not constitute the whole public. Some years ago this influence was more marked than at present. The public saw the exertions made by the medical examining bodies to raise the standard of qualification; they had some idea of the rapid progress of our science; now and then they got some glimpses of our doings through the medical journals, which were then assuming a great degree of activity. In society they met the members of our profession, and they could not but observe their growth in intelligence and general accomplishments. But within the period, the review of which has presented us with matter for honest exultation as a profession, two notable heresies have sprung up, and have succeeded in obtaining not a few victims from the laity, and some converts, or perverts, from our own body.

We cannot blame the public. Ignorance is an object of pity, not of reprehension. And surely to a non-professional mind there is something quite charming and seductive in these so-called systems of cure. To wash away all taint of disease, all dregs of the nauseous and noxious drugs that had been imbibed in the days of darkness—to cleanse all this by pure water, within and without, is a notion that carries refreshment into the depths of the inner spirit, and makes one indulge in delightful transcendental visions of the regenerating efficacy of this corporeal baptism. Not less attractive is that system which banishes all the bugbears of the nursery and the sick-room,—which puts aside *omne quod exit in um, præter remedium*, presents *that* in an insensible fraction, undistinguishable from the sugar or the water that contains it, and bars out all the terrible inflictions of the antiphlogistic regimen! Yes, let us consider very leniently the adhesion of the laity to systems adapted to a love of simplicity and to an abhorrence of temporary suffering even for ultimate good. It is so delightful to travel by royal roads to health as well as to learning. They do not know the dangers of the road, and what benefits they lose for ever by the irreparable loss of time. They cannot follow the reasoning involved in medical proof. Why do they ask *our* aid? They may know that we have been diligent in acquiring professional knowledge; that we are reputed for skill and experience; that certain of their friends were seriously ill, and that while under our care they recovered. But they may say to themselves, "Doctor Aquaticus and Doctor Minimus have received a regular education; they must be learned men. Dr. Aquaticus cured Mrs. Weakly of that inveterate lumbago that had resisted even Holloway's pills; and our little nephew has, by the help of Dr. Minimus got through the measles, and without one of those abominable black doses, the very sight of

which used to throw him into such terrible rages. Why should not we, too, send for Dr. Aquaticus or Doctor Minimus?" We cannot prevent these processes of thought and their practical results, till the public mind is better informed. The best thing we can wish, both on their account and our own, is that they should study physiology, and learn some rudiments of pathology, sufficient to assure them of the rational basis of medicine, and that their true safety depends upon it. We have nothing to fear from the illumination of the public. We do not shun the light. We do not depend on mystery. Ours is not an *occult* art. No initiatory rites are needed save those which are involved in the study of nature in health and disease. We court inquiry; and those who look *deepest* into our principles and proceedings are those from whom we have least to fear. Not to *us* and to *our* science can be applied that mournful complaint that

> "Those who know the most,
> Must mourn the deepest o'er that fatal truth,—
> The tree of knowledge is not that of life."

For ours is not forbidden knowledge; nay, we are invited to it by the gracious author of our being, through various analogies in nature, and ten thousand hints from "healing balm and medicinal gum."

Were other evidence wanting to prove that the honest well-educated practitioner prefers laying open his processes to those who can understand them, (for certainly it is of no use to ask for or permit the presence and spectatorship of those who do not understand what he is about,) I may adduce the willingness with which he submits his views and his treatment to the scrutiny of any honourable well-instructed professional brother. He may fear the semivision and senseless gossip of the laity; but he has nothing to dread from the observation and the report of a scientific and experienced witness. I confidently appeal to the high-minded skilful practitioners by whom I have the honour to be this day surrounded, whether it has not always been a relief to them, during the conduct of a difficult case, to find some medical friend or relative of the family who, though not sharing the responsibility, has the opportunity of ascertaining their opinions correctly, who can enter into their perplexities, and who can understand the indications of cure or relief which they are endeavouring to fulfil.

But I cannot conclude this subject without alluding to those who have become separatists from our professional communion. I do not ask you to condescend to think of those who never were of us,—those insolent pretenders who, from the walks of common life, and without any training whatsoever, have dared to assume the garb and wield the staff that should be handled by none but true Asclepiadæ.

> Misericordia e giustizia gli sdegna:
> Non ragioniam di lor, ma guarda e passa.
> (Mercy and justice scorn them both,
> Speak not of them, but look, and pass them by.")

But what shall we say of those who once knew better things,—those apostates from the faith handed down to us by Hippocrates and Sydenham? Simply that they have cut themselves off, and that we hold them as cut off. As practitioners we will have nothing to do with them. They have no part or lot with us. They have chosen to stray: let them go, and they leave no very deplorable hiatus.

Yet, let me guard this dismissal with one exception; I would not include in it any honest hydropathic practitioner, who regards the water-cure as only a branch of therapeutics to be used in alliance with regular medicine. On the contrary, one would gladly hail such auxiliaries; for that there is a potency for good as well as for evil in that method cannot, I think, be denied. Indeed, it would be strange if the constant employment and observation of such an agent as cold water had not led to some improvement in the application of it, and to some extension of our knowledge of its powers. We only pronounce our ban on those who declare hydropathy to be the only proper method of treatment, or, who use it in conjunction with homœopathy and mesmerism. Have we any like exception to offer in favour of homœopathic practitioners? None. For them we have no qualification or mitigation of our sentence. On them the science of medicine pronounces its distinctest and deepest-toned anathama. But, setting medicine aside, common sense derides them, humanity reproaches them, and reason sets upon them the ineffaceable brand of *impostor* or *simpleton*. Is this harsh and intolerant language? It is not. Can any terms from us be too severe or contemptuous towards those who urge us to turn our backs on that august temple of medicine, whose foundations are laid deep in nature, whose pillars have been slowly raised by the science and art of successive centuries; and whose precincts are consecrated by the genius, the devotion, and self-sacrifice of some of the world's greatest benefactors;—and who bid us to go and worship in that miserable tent, which was stretched out but yesterday, and where the mutterings of its half crazy fabricator are mistaken for the responses of an oracle.

Are we intolerant? No. We extend our Christian charity to the utmost over the motives of the poor perverts. But while we are ready to admit the purity of their intentions, we do not choose so to insult *our own* understandings, as to say that we feel the smallest respect for *theirs*. They may be good and amiable; but we decline assenting to the assertion of their wisdom. Men who can imagine that most chronic maladies owe their origin to the itch, and who really believe as to the infinitessimal dosings, what can easily be reduced to a mathematical absurdity, are surely not to be placed in the same category as those children of whom their parent is said to be justified. I forbear inquiry into the consistency of those disciples of Hahnemann, who depart from his system of dilution, and who can reconcile it to their notions of propriety to recommend castor oil and cod-liver oil, to administer enemata, to apply blisters and fomentations, and to call in what is frequently the perilous aid of hydropathy. I do not inquire into this, lest we should end in the conclusion that their consciences are attenuated almost in the same degree as their doses. Besides, we may

leave them to the expostulation and reproof of the more faithful of their brethren, who will certainly not fail to hurl at them some denunciatory text from the dreamy delirious revelations of their prophet Samuel! But you may say, surely not all of them are simpletons: surely some of them have shown ability in other matters. It may be so. I am not here to inquire what precise amount of mental soundness or capacity is compatible with a belief in the homœopathic system. It would border on such medico-legal investigations as those in which we have to ascertain whether competence to the management of affairs may be predicated of a mind that is subject to some particular delusion.

That laymen of great powers of mind have adopted homœopathic treatment for themselves or their families, should go for nothing. They are not led to it by reasoning, but by what they fancy to be experience, and which is indeed only empiricism. Every pestilent quackery that has ever been palmed upon the world has numbered among its victims the wise and the witty, as well as the dull and the ignorant. And the wise have adopted it because they have not been wise in all things. They were sick; they swallowed decillionths of oyster shells; and they got well. This is their argument, and its fallacy is too obvious to deserve even a momentary comment.

Pardon this long digression; but the subject is so important that it ought not to pass without some emphatic notice. I strongly advise my brethren to take an uncompromising part, not only by refusing to co-operate, even in the most indirect manner, with homœopathic practitioners, but also to show the public in what light we regard these marauders. I need not tell you that the only really remunerative cases to the general practitioner, (except in the feeling of satisfaction in the discharge of an arduous duty, in the achievement of success in a difficult art, and in the thought of having saved a life, or assuaged pain and distress,) are those in which his duty consists mainly in standing by the bed-side of the patient, ready to interpose, if in his judgment any emergency arises; though they are cases to the cure of which nature alone is usually adequate. Nothing can really compensate him for the anxiety incident to the life-and-death encounters in grave cases, to say nothing of fatiguing days and broken nights. If, therefore, his attendance is sought by a family in such cases only, (and the instinct of the patient or his friends will generally lead them away from homœopathists on such occasions,) he is justified in requiring that his reward should be very different from what it is when he has all kinds of cases submitted to him.

I have no fear that this view of the case can be considered mercenary. Everywhere it is allowed, that from no profession is more gratuitous aid received by the public, and I am proud to believe that it is held to be one of the highest privileges of the profession that it has the power, and is allowed to render help to mankind as a labour of love. But as our patients often quote to us, "The labourer is worthy of his hire," so we may urge that the hire should bear relation to the kind and the degree of the labour. To employ a soldier on no service but fighting in pitched battles, bivouacking on malarious plains, or leading the "forlorn hope" of a storming party, and then to tender him for such service the same pay as a soldier who is engaged all the year round, and has ordinary garrison duty, or the light routine of the parade ground, in a frequent exchange for the hardships and perils of a campaign, would surely be considered to be very unreasonable and very unjust, yet it is a case precisely parallel with that to which I have just adverted.

I trust that I have not gone too near the borders of levity in some of the remarks which I have ventured to offer to your consideration. Believe me that no one can feel more deeply than I do the seriousness of medical practice. We ought ever to nourish a sentiment of reverence for our art, and a solemn conviction of the weightiness of the interests which are involved in it. To say nothing of the value of the lives of the good, the great, the wise, the brave, and the beautiful, the issues of which are in our hands as far as they can be in mortal power; to say nothing of our high vocation of imparting succour and relief to the helpless and suffering, we ought to go to our work in the spirit of priests and hierophants—men who have to minister in holy things, men who have to tend the sacred lamp of life, to guard and sustain the temple of the human body—that fabric on which creative power has lavished most marvellous resources, most consummate artifice. Let us constantly bear in mind that pregnant saying of the German sage, Novalis,—"We touch God when we lay our hands on a human body;" so shall we approach it with fitting reverence.

SUCCESSFUL CASE OF

OPERATION FOR THE REMOVAL OF AN OVARIAN TUMOUR,

WEIGHING TWENTY-FIVE POUNDS.

By JOHN BEALES, Esq., M.R.C.S., Halesworth.

Read at the Suffolk Branch Meeting, at Framlingham, June 27, 1851.

In the early part of September, 1850, I was consulted by Eliza Smith, of Darsham, aged 30, unmarried, for an enlargement of her abdomen, resembling that of a person at the full period of pregnancy. She stated that she had lived in the capacity of lady's maid for the last two years; that in December, 1849, she discovered an enlargement of the left side of her body, which gradually increased up to the month of August, 1850, when she was obliged to seek medical relief for loss of appetite, loss of strength, with wasting of her legs and arms. During the progressive state of this enlargement the catamenia were regular up to the month of April, after which time they returned every fortnight, up to the following August, but in small quantity. During this period she was perfectly free from pain, and her general health suffered but little. Upon examina-

tion I found an ovarian tumour, of a circumscribed character, extending from the left iliac region to the left hypochondriac, very hard to the touch, but towards the umbilicus and scrobiculus cordis soft and fluctuating, as far as the right hypochondriac and the right iliac regions, but evidently in two distinct sacs, moveable as a whole, and free from pain or tenderness, measuring thirty-seven inches in circumference; the patient being only four feet eleven inches in height. The uterus was healthy, high up, and of small size.

From the mobility of the tumour, and from the absence of pain at any time, I proposed the operation of its extirpation by the large incision, which was eagerly acceded to by the patient herself, having also had the sanction of two of my medical friends, as to the propriety of the step.

About the middle of November I removed my patient to a lodging in my own town; and on December 4th I performed the operation, in the presence of several of my medical friends. She took the night before, Extr. Hyoscy., gr. iv.; Extr. Col. c., gr. vj. Ft. Pil. iij.; and had an enema early on the morning of the operation, which cleared the bowels well. My patient was seated upon a couch with her feet upon the ground, and her back supported by a bed-chair and pillows; an eight-tailed bandage having been first placed behind her. Mr. Archibald Dalrymple was seated upon my right to receive the tumour, and Mr. Crowfoot on my left to guard the intestines should they escape at the wound. Mr. Donald Dalrymple kindly administered the chloroform, and she was fully under its influence in about two minutes. Having seated myself nearly opposite to my patient I commenced an incision of the integuments and the peritoneum just below the umbilicus, to an extent of four inches, to within an inch and a half of the symphysis pubis. The fingers of my right hand were passed into the peritoneal cavity, and a few adhesive bands were gently separated on both sides of the wound. The cyst was fluctuating and yielding on the right side, but firm and hard on the left. I then enlarged the incision of the integuments, beginning about three inches below the scrobiculus cordis in the linea alba, and extending it down to the left side of the umbilicus, a distance of six inches, to join the one of four inches made in the first instance. With a blunt-pointed bistoury I divided the peritoneum to the same extent. The wound expanded, but the tumour seemed immoveable. Unintentionally I opened a thin part of one of the cysts, when several pints of thick gelatinous fluid escaped. The tumour was still stationary, so that it became necessary to puncture another sac, when, after drawing off three or four pints of fluid of the same character, the tumour was slowly and gently removed from its cavity. I then, with a curved needle fixed in a handle, with an eye near its point, passed a double ligature of strong silk through the pedicle and tied it in two separate places; but in so doing the silk of one ligature broke, which was immediately replaced by passing an eye probe, armed with another double silk ligature, through the aperture made by the curved needle, and firmly tied. The tumour was then separated with a scalpel as near as possible to its base. No blood escaped. The uterus was felt, and found to be small and healthy, as well as the right ovary. The integuments appeared almost to close of themselves, and were immediately secured by seven interrupted sutures. The patient was then put to bed, being still and having been under the influence of chloroform for about twenty minutes. She shortly afterwards became sensible. Long pads of lint were placed on each side of the wound, and secured by strips of mild adhesive plaster from one side of the body to the other. The eight-tailed bandage was crossed in front of her and made secure.

Her pulse, before the operation, which took place at twelve o'clock, was 65. At two P.M. it was 80, and she complained only of a general aching. Ordered a quarter of a grain of morphine, in an ounce and half of camphor julep. The temperature of the room to be kept at 75°.

At seven o'clock in the evening her pulse was 96; skin moist; no pain, but a little uneasiness in the bladder.

Half-past nine, P.M.—A little restless; drew off by the catheter half a pint of urine. Repeat anodyne. Ordered half a pint of toast and water for the night, having taken half a pint since the operation. Pulse 96.

December 5th.—Half-past nine A.M.—Has passed comfortable night, with frequent quiet sleeps of twenty minutes at a time; pulse 102; skin moist; tongue moist; has taken nearly a pint of toast and water; countenance cheerful, and says "she does not feel ill;" drew off ten ounces of urine; wound looking well; tightened the bandage; no swelling of abdomen.

Half-past two, P.M.—Has slept for three-quarters of an hour, when some person opened her bed-room door suddenly, and awoke her; pulse 115; skin moist; tongue moist; a little aching at the top of both hips; drew off six ounces of urine; pulse after it 106; has drank half a pint of toast and water since the morning.

Half-past nine, P.M.—Pulse 106; skin moist; tongue moist; a little irritation at the neck of the bladder; drew off five ounces and a half of urine; pulse 100 after it. Repeat anodyne draught.

December 6th.—Ten minutes past nine A.M.—Has had several hours' sleep during the night; awoke at half-past three this morning, and vomited a good deal of green bile, went to sleep for an hour after it, and vomited again; pulse 106; tongue moist, but furred a little at the back part, the tip red; skin moist; wind rumbling in the bowels; the body flat, and no tenderness; feels better since the discharge of bile; drew off half a pint of urine, not high coloured; has taken but little toast and water during the night; is cheerful; the countenance rather sallow. Ordered soda water.

Half-past two, P.M.—Pulse 106, rather full and hard; temperature of room 70°; has taken only two wine-glasses of soda water since the morning; wind in the bowels causing a little pain; no enlargement nor tenderness of the body; urine *not* drawn off; tongue moist,

Quarter to ten, P.M.—Pulse 106, and soft; skin and not so furred; skin comfortable.

moist; tongue cleaner; countenance cheerful; herself in excellent spirits; has had an hour's refreshing sleep during the evening; has passed wind per rectum; drew off nine ounces and a half of urine; temperature of room 75°; wishes for her anodyne. Continue toast and water in the night, or soda water. Pulse 100 at ten o'clock.

December 7th.—Half past nine, A.M.—Pulse 100, and soft; skin moist; has slept six hours during the night; is cheerful; drew off nine ounces and a half of urine; wound healthy, and closed by adhesion; drank half a bottle of soda water during the night; would like some breakfast. Ordered *one* biscuit in a cup of tea, and a domestic enema of gruel. Temperature 70°.

Four o'clock, P.M.—Pulse 106; skin moist; has had the enema; half returned dirty, with a great quantity of flatus; did not want to pass water. The nurse had put on clean linen, *contrary to orders*, which accounted for the increase of pulse since the morning.

Half-past nine, P.M.—Pulse 102; tongue moist; skin moist; very cheerful, and says she has passed water at half-past five this evening, eight ounces and half in quantity; has had three quarters of a tea-cup of gruel. *Not* to take the anodyne unless in pain or restless, but to have soda water and a tea-cup of gruel during the night.

8th.—Ten minutes past eleven, A.M.—Pulse 96; tongue clean; skin moist; in excellent spirits, and wants something to eat; had six hours sleep *without* the anodyne; has passed half a pint of urine at four this morning, and seven and half ounces at nine; also a good deal of flatus per rectum; wound healed; removed *all* the sutures; ordered a cup of tea and a soft boiled egg; she drank half a bottle of soda water in the night, and a cup and half of gruel.

Four o'clock, P.M.—Pulse 115; tongue moist; skin moist; had been a little excited, hearing me complain down stairs of the door of the house being left open. Ordered a cup of tea and a little dry toast.

Half-past nine, P.M.—Pulse 100; skin moist; tongue clean and moist; passed six ounces and half of urine; bowels *not* relieved; ordered half an ounce of manna in half a pint of gruel; during the night says, *she should not know she had a wound in her body at all;* has passed wind per rectum.

9th.—Eleven o'clock, A.M.—Pulse 90; skin moist; tongue clean; has had a good night, and has passed ten ounces and a half of urine at two different times; took the manna; feels as if the bowels would be relieved; enjoyed an egg and dried toast for breakfast, with tea and milk; a thick deposit of urates in the urine.

Nine o'clock, P.M.—Pulse 90; skin moist; tongue clean; very easy; feels as if the bowels would be relieved; has drunk nearly a bottle of soda water; some gruel and half a cup of tea this evening, with a piece of brown dried toast, with a little honey upon it; ordered one pill of Pil. Hyd., gr. j.; Ext. Col., gr. ij.; Pil. Rhei., gr. ij.; Ext. Hyoscy., gr. j.; and gruel in the night; body perfectly flat and easy; and has passed flatus per rectum.

10th.—Eleven, A.M.—Pulse 90; skin moist; tongue clean; free from all uncomfortable feelings; has slept six hours; passed eleven ounces and half of urine since the last evening, and has had one copious pultaceous motion of healthy colour; has had a cup of tea with an egg in it for breakfast, and some dry toast. Ordered a custard pudding and soda water for dinner.

Half-past eight P.M.—Pulse 96, soft; skin moist; tongue clean; felt a good deal of pain in the back; felt as if she would be unwell; has passed a pint and a quarter of urine since the morning; enjoyed her pudding and soda water for dinner; wound from the ligatures discharging healthy pus.

11th.—Half-past two, P.M.—Pulse 96; skin moist; tongue clean; has had relief in the bowels and has passed three quarters of a pint of urine, and slept six hours. Ordered arrow-root pudding and beef-tea for dinner; a little jelly occasionally; discharge by ligatures healthy.

12th.—Visit twice; pulse 90; going on well.

13th.—Ten minutes to one, P.M.—Pulse 90; bowels relieved; tongue clean; complains of a little sickness. Ordered beef-tea and pudding, with a little wine and water.

Eight o'clock, P.M.—Pulse 100; feels weak; great discharge from the wound by the ligatures. Ordered a pint of beef-tea in the night, and wine and water if faint. Pulse increased, by the nurse allowing two strangers to visit her, *contrary to orders*.

14th.—Has had a good night; pulse 100; tongue clean; bowels naturally relieved; great discharge from the wound. Ordered chicken for dinner, and wine and water.—*Vespere:* Pulse 90. Discharge less.

15th.—Pulse 82; tongue clean; discharge less, and feels better.—*Vespere:* Pulse 80. Has taken mutton chop and wine and water for dinner. From this date she went on well, with daily relief in the bowels, good nights; was able to sit up and walk about her room every day, taking mutton, beef, or game for dinner, and a glass or two of port wine.

25th, (Christmas day.)—One ligature came away, the discharge became less, and on the 30th of December the other ligature came away. The first ligature came away on the twenty-first day after the operation, the second on the twenty-sixth day.

31st.—Is very cheerful; wound where the ligature came out yesterday just healed; *no* discharge, and *feels perfectly well*. I examined the uterus per vaginam, and found it high up, but quite natural.

January 1st, 1851.—Came down stairs perfectly recovered *exactly* one month from the operation.

5th.—Catamenia returned, and lasted four days.

11th, (Sunday.)—Went to church in the morning.

Circumference of the abdomen *before* the operation thirty-eight inches and a quarter. Length from scrobiculus cordis to symphysis pubis, *before* the operation, fifteen inches. Length of incision ten inches. Circumference of the abdomen, six weeks *after* the operation, twenty-six inches and a half. Length of cicatrix seven inches and a half.

Description and dissection of the Tumour, by Mr. Donald Dalrymple.—The tumour, which measured,

after removal, three feet two inches in its *largest* circumference, and two feet one inch and a half in its *smallest*, and weighed twenty-five pounds, presented a smooth shining surface of peritoneal covering. It was a multilocular cystiform tumour, marked by several lines or bands of a denser, whiter, fibrous tissue than the rest of the cyst, corresponding with the septæ of the cysts. The walls of the cysts are composed of three distinct coats:—*First*, a peritoneal layer; *secondly*, a middle or fibrous layer of unequal density; and *thirdly*, a rather thick membranous sac, containing fluid. The peritoneal coat is thin, smooth, and shining, and free from any of those opacities which result from inflammatory action; it is very closely attached to the fibrous layer, except at the pedicle, where it was loosely reflected, and gave passage to several very small arteries, (*i. e. very* small compared with the size of the tumour), none being larger than a common probe; several much larger returning veins, and several nerves. The middle coat is also thicker at the root, and on it ramify the arteries, veins, and nerves. It varies much in density, and at the periphery of some of the cysts it is very thin. The inner coat has the appearance of having in some of the cysts, two layers. This is more distinct in the smaller than in the larger ones. The membrane is slightly rugous, and varies in colour; in some places pale, in others of a slight ochre colour, with many minute vessels ramifying on it. Some of the cysts are very *large*, containing three to four pints; some very *small*, and placed one within another like a nest of boxes; at one point as many as five are so placed. The fluid varies in density and tenacity in the different cysts; in the *smaller* ones being clearer and thinner; in the *larger*, more thick, and of a yellowish green hue. The average specific gravity 1010. It contains a very large proportion of albumen, more than its specific gravity would have led me to believe. It became putrescent in about fifteen days when exposed, evolving ammonia and sulphuretted hydrogen very freely.

I should estimate the quantity of fluid at about twenty-two or twenty-three pints, counting what was lost at the time of the operation.

CASE OF A RARE VARIETY OF SPINA BIFIDA.

By EDWARD T. HUGHES, M.D., Mold.

Read at the North Wales Branch Meeting, held at Denbigh, June 17, 1851.

John M., aged 24, well made, and enjoying robust health, applied to me on the 8th of July, 1846, for advice respecting a tumour situate over the left buttock, which had burst on the previous evening, and discharged a large quantity of a thin, clear, colourless fluid, and to day, during his walk to Mold, a distance exceeding three miles, had continued to do so most profusely. The tumour, previous to bursting, was described to me as being the size of a man's head, and occupied the whole length of the sacrum and coccyx, extending a little over the mesial line on the right side, but on the left covering half the buttock. It was not painful to the touch, except at the part where it had given way, which was rather below its centre. The feel of its lower portion was thick and fleshy, but in the upper, notwithstanding the wrinkled state of the skin evinced its greatly diminished size, fluctuation was evident, and by slight pressure the escape of fluid was materially increased.

The outer envelopes of the tumour appeared to have undergone a gradual process of thinning, and to have given way from this cause rather than from any ulcerative process; and, deprived of their support, the sac had in like manner been unable to resist the pressure of its contents, which now filtered through a network of delicate fibre, formed by the separation of its tissue, to the extent of a square inch. The external surface of the sacrum was not at all tender to the touch; but at the junction of this bone with the coccyx there was a distinct opening, and the part when pressed was painful. I carefully examined the whole length of the spinal column, and could not discover any defect or tenderness. He had not at any time experienced either numbness or debility of the limbs. His head was well formed. His senses were perfect. The only particular worthy of notice was the dilated state of the pupils, which in no way affected his vision. Beyond the discomfort occasioned by the constant dribbling from the swelling he made no complaint, its reduction in size being rather a relief than otherwise. The fluid, on examination, exhibited slight traces of albumen.

The following history confirmed my opinion that the case was one of spina bifida:—

Soon after birth a tumour, the size of a walnut, was discovered, extending from the junction of the sacrum and coccyx half down the latter bone; at first it increased slowly, but at the age of thirteen was the size of an infant's head. During his earlier years, and when his own recollection will not serve him, his mother states him to have been a healthy boy, with the exception of occasional headaches, which were always brought on by stooping. When nearly twelve years of age he went into farm service, but when the potato and turnip harvests arrived, and he was obliged to stoop much, his headaches became so frequent and violent that he could not remain in his place. He received little sympathy from his employer, as, in other respects, he bore so completely the appearance of strong health. He describes the pain as dull and heavy, referrible to the fore-part of the head, and always relieved by lying down. He was at this time under medical treatment, but received no benefit from it, for the tumour had not as yet appeared in any way to influence his complaints, and was not mentioned. When thirteen years old he struck it, and was immediately seized with intense headache; from being full and firm it became soft and empty, and it was not until (after several days) it recovered its original condition, that his head was relieved. Position had hitherto in no way interfered

with his comfort, but he could never after this lie on his back without inducing headache. The most remarkable effect, however, was that he no longer felt any inconvenience from stooping, as had previously been the case, but was accustomed to relieve his headaches by bending his head lower than his body, and thus has been able to do work which he could not otherwise have attempted. During the last eight years the tumour had gradually increased to at least double its former size. Whenever he hurt it he uniformly suffered severe headache, it became soft and flaccid, and no relief was ever experienced until, as in the first instance, it recovered its accustomed form. In other respects his general health has been very good, and during the last two years he has worked underground as a lead miner. A fortnight ago, while at work, he struck the tumour a severe blow, and since that occurrence its increase in size has been much more rapid than on any previous occasion, until it burst yesterday.

He was sent home, and directed to apply water dressing to the sore, to remain in bed, and take aperient medicine if required. On the evening of July 10th he had considerable pain in his back, and heat in the tumour, which was relieved by free discharge from it. On the 11th I pressed out about half a pint of curdled matter from it, without pain. He was ordered to lie on his left side, so as to favour the discharge, to continue the water dressings, and to take a dose of saline aperient medicine twice or three times a day. On the 13th he was better, the tumour was of a more fleshy consistence, and much diminished in size. On pressing in every direction, not more than a teaspoonful of thick purulent matter was discharged. From this date to the 28th he improved; the tumour was gradually assuming a firmer feel, and was much diminished in extent; the discharge from it healthy, and in sufficient quantity. His appetite was good, he slept well, and every symptom led to the hope of a favourable result, when on the 29th he was attacked with pain in the head, and along the whole length of the spine. There was no discharge from the sore, and the muscles of the back were in a perfect state of opisthotonos. General and local bleeding, with other active treatment, was unavailing. He became paralyzed, coma supervened, and he died on the morning of the 2nd of August.

I regret that an examination of the body was not allowed.

The foregoing case is interesting, inasmuch as very few of the subjects of spina bifida attain adult age.

A case, in some particulars similar, is related by Mr. Dawson, of Liverpool, in the first volume of the "Transactions" of the Association. The patient, a lady, 38 years of age, had a tumour on the upper and back part of the thigh, about the size of a pomegranate, which was the source of much discomfort to her, and she consulted the late Mr. Park as to the propriety of its removal, for which she was anxious. On manual examination it appeared to be fibro-cartilaginous, with a small quantity of fluid occupying its apex. It had existed from birth, and when first discovered was the size of a filbert. It was punctured, and twelve ounces of clear fluid discharged; after its collapse its connection with the spinal column was traced through an opening between the sacrum and the coccyx. She lived nineteen days after the operation. The details are long and interesting, and well worth attention.

As the tumour had burst before I saw my patient, I was relieved from those difficulties of diagnosis which spina bifida, in so unusual a situation, might have presented. I had, also, been much interested in the perusal of Mr. Dawson's case, and could not fail to recognize the points of similarity between the two.

Mold, June 25, 1851.

ON THE

MANAGEMENT OF WOMEN AT, AND AFTER THE CESSATION OF, MENSTRUATION.

By E. J. TILT, M.D.,

Senior-Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Dispensary for Diseases of Women and Children.

Sedatives.

When relating the successive variations of practice which have occurred in the administration of our most valuable medicines, the medical historian will probably state, that during the last thirty years there has been too much timidity in the employment of sedatives, and particularly in that of opium, for the present generation of medical men seem to forget that often nature only requires to be freed from present pain, to enable an organ to return at once to the regular performance of its function, without future distress or inconvenience. Is it, then, necessary to remind the reader, how generally useful sedatives are, that in most diseases they not only assuage the acuteness of pain, but lull excited action to a slower rate of progress, and to a more subdued tone. The blood-vessels serve under the immediate rule of the accompanying nerves; and hæmorrhage as often depends upon their purturbed agency as on any peculiar state of the blood-vessels themselves; and although other measures may be indispensable, the return of such hæmorrhages can only be prevented by a judicious use of sedatives.

We have already seen how useful is opium in the relief of many deranged states of action, particularly in dysmenorrhœa, and the utility of sedatives in diseases of the change of life might be deduced from the great frequency of cerebro-spinal symptoms at the cessation of menstruation. It will be remembered that I stated their frequency to be—

Cerebral Symptoms.

Headache, sick-headache, hysteria, and pseudo-narcotism had existed in ...	64	per cent.
They were augmented in	36	,,
,, remained the same in ...	18	,,
,, were less in	10	,,
They did not exist in	36	,,
	100	

Spinal Symptoms.

Spinal or dorsal pains had existed in ...	70	per cent.
They were augmented in	46	,,
,, the same in	17	,,
,, less in	7	,,
They did not exist in	30	,,
	100	

Hypogastric pains of a bearing-down character, referred by women to the womb and ovaries, had existed in ...	51	per cent.
They were augmented in	30	,,
,, the same in	12	,,
,, less in	9	,,
There were none in	49	,,
	100	

This frequency of cerebro-spinal symptoms warrants an equally frequent exhibition of sedatives, and I do not hesitate to say that, under some form or other, they are always required in diseases of cessation. In the milder forms of catamenial headache and pseudo-narcotism they alone suffice to cure, and they always assist the action of bleeding, of purgatives, and of other remedies which may be deemed necessary.

To relieve the cerebral symptoms, which, though cured, so frequently return, I very seldom make use of opium, but, on the contrary, give hyoscyamus, the mild action of which permits its being taken longer without producing cerebral disturbance or constipation. When there is any great intensity or persistence of spinal or hypogastric pain, I generally give from thirty to forty drops of vinum opii in three ounces of very thin starch, as an enema, repeating the remedy according to the urgency of the case, one, two, or three times a day. Thinking that the outward application of sedatives has been too much neglected, I frequently order the ordinary opium or belladonna plaster to the sacrum, to the loins, and even to the pit of the stomach, whenever the patient complains of a "fainty feeling," or of "sinking at the stomach," or "of having no inside." In such cases, I often prescribe a plaster made so as to embody from five to ten grains of opium and the same quantity of camphor to the square inch. Such applications to the epigastric region are too often said by the patients to give great relief, for me not to believe that sedatives thus applied to so important a centre of nervous force must be worthy of an extensive trial; for it is indeed strange that a region of the body to which patients so often refer their sufferings, the application of a small blow to which causes so much debility, while sudden death is the speedy consequence of its more violent concussion—I mean that epigastric region considered by the great Galen to be one of the levers of vital force, the ὑπομοχλιον,—should remain all but unnoticed by physiologists, unmedicated by therapeutists, and a region almost entirely unexplored. If, in my hands, the lever has well answered to the touch, how much more, when handled by fingers directed with superior skill, would it enable others to use the innate powers with which we are endowed by nature for the more speedy cure of disease. An additional motive for laying stress upon this point of practice is, that in the profession I have frequently seen an inclination to undervalue the effects to be obtained from topical applications. It was only lately that the well-informed resident officer of one of the public institutions to which I belong said to me, when I was complaining of my patients not having the plasters I prescribed, "I have too high an opinion of your practice, sir, to think that you can hope to cure your patients by *plastering up disease*." I own that I felt somewhat disarmed by the compliment.

Dr. Physick used to say that "camphor was made for women, with whom it always agrees, while it always disagrees with men," thus placing two exaggerations in a small compass; for I have met with women with whom it disagreed, and it agrees with men who, by their constitution, approximate to women.

Camphor has been so often lauded in the diseases of women, that I may be allowed to add my humble testimony to the value of a remedy, without which I should be at a loss to treat diseases occurring at the cessation of menstruation. I generally prescribe the ordinary camphor mixture as a vehicle for other remedies; but where expense is no object, Sir James Murray's fluid camphor is a preferable preparation.

Descending from these general observations to those of more practical application, I shall give a few cases exemplifying my plan of treatment.

Case 14.—Mary B——, a needlewoman, aged 48, with auburn hair and blue eyes, is tall and stout, and has lived always in the country. She applied for relief at the Paddington Free Dispensary, Feb. 6, 1851. She first menstruated without any prodromata, between thirteen and fourteen years of age. It was very abundant from the first, and the function was regularly performed every four weeks, without much pain. She married at twenty-five, had one child, and two miscarriages. For the last eight months, the menstrual flow had become irregular, sometimes very little, at others abundant, and attended by great flushes of heat, perspirations, a great darting pain in the forehead, and a dizzy stupid feeling in the head, with a great tendency to sleep.

I ordered a mixture composed of solution of potash and tincture of cardamoms, of each four drachms, with six drachms of the tincture of hyoscyamus, in six ounces of camphor mixture; a table-spoonful to be taken with a little water ten minutes before every meal; and half a tea-spoonful of bicarbonate of soda, with a little powdered ginger, to be taken in a wine-glassful of cold water, ten minutes after each meal.

I also ordered five or ten grains of the soap and aloes pill, to be taken at night, when necessary, to maintain the free action of the bowels.

This was continued until the 27th February, when, instead of the aloetic pills, I ordered the following powder:—Flowers of sulphur, two ounces; bicarbonate of soda, two drachms. A teaspoonful to be taken in a little milk, every night.

Under the influence of this treatment, and perhaps, also, from the occurrence during the treatment of a papular eruption, accompanied by intense itching, on both hands and arms, the head symptoms soon disappeared. After a severe accession of influenza, she was

again attacked by them, but they again vanished, when the same treatment was had recourse to.

Remarks.—The compound camphorated mixture, as prescribed in this case, is what I usually give, but I vary the proportions of its ingredients according to circumstances, and that it does good is, I think, proved by the fact, that at the public institutions to which I am attached, I am very frequently applied to by my old women, for "some more of the same stuff which did them so much good before."

The administration of alkalies, which form so useful an addition to the treatment of such cases, improves digestion, and by their action on the blood they doubtless neutralize some of its noxious elements. Their utility will be still further understood, if it be admitted, as I have frequently observed, that notwithstanding the use of diuretics, the urine previous to, and at cessation, is often secreted in smaller quantity, that it is very muddy, and that the patient suffers from a certain amount of general excitement. This condition of the urine at the change of life reminds me of another very important phenomenon of menstruation, to which I have not drawn more particular attention, because I have not as yet been able to work out its value; I allude to the state of the urine previous to the catamenial periods, when some of the nervous symptoms of menstruation have already appeared. Since my attention was first drawn to the subject, by learning from a patient "that she always knew when she was going to be *poorly*, by her urine being so very muddy," I have made it an object of inquiry. It has often escaped notice, but most women have stated to me that their water was generally thick and muddy two or three days previous to menstruation. This condition of the urine, which, I believe, has never before been noticed, as well as the catamenial diarrhœa, to which I shall allude in treating of purgatives, and the frequency of the nervous symptoms, show indubitably how deep a modification is produced every month in the female constitution. These are the evidences of that species of fermentation admitted to exist at the menstrual periods by Bayle and Etmuller, by De Graaf and Van Helmont;—this is the peculiar commotion of the blood which Democritus had in view when he talked of a "fervor uterinus." In dispensary practice it is impossible to carry out the investigation of the value of this phenomenon, and to inquire into the nature of the saline deposits alluded to by my patients, but those who, being attached to hospitals, enjoy the enviable fields of inquiry which charity lends to science, in the anticipation of a return, might easily arrive at results which would, I think, be interesting to physiologists.

I usually give the sesquicarbonate of soda, bicarbonate as it is now called in the new Pharmacopœia of the College of Physicians, because it is convenient, cheap, and not unpalatable. After the first few days I give it only once or twice a day. In mild cases, and in those of long standing, I continue this treatment for a month, and then leaving it off for a fortnight, resume it again, combining its influence with that of a tepid bath every week, with sponging the head several times in the day with cold vinegar and water, or camphorated water, and having the feet put for a quarter of an hour every other night in hot water.

It may be said that the preceding case was slight, and that although my treatment did no harm, time alone cured the patient; but the following case will be better calculated to show its efficacy:—

Case 15.—Eliza P———, aged 47, tall and slender, with dark hair, hazel eyes, and nervous appearance, has always lived in London, and is in comfortable circumstances. Menstruation, after three months of pseudo-narcotism, appeared between thirteen and fourteen. Regular from the first, it came every three weeks, in moderate quantity, and without any pain. She married at sixteen, miscarried three times, had seven children, and menstruation ceased, with a terminal flooding, at forty-four, after eighteen months' of menstrual irregularities. About a year ago she was troubled with nervous symptoms similar to those I am about to describe, and followed by copious hæmoptysis, which relieved her. The patient often suffers much from faintness, flushes, perspirations, and lately, to a slight degree, from bleeding piles. She looks exhausted, stupid, and bewildered, and says that for the last few weeks her head has been "as heavy as lead," with noises and great giddiness. Every now and then she feels a burning heat run across the chest, and through the body; and then follow profuse warm perspirations from the chest only. She compares her sensations to those by which the hæmoptysis was preceded.

I first saw her on April 3rd, when I ordered the same treatment as to the former patient, with the exception of six drachms of tincture of henbane to the six-ounce mixture, of which a table-spoonful was to be taken four times a day. I also ordered a large plaster of opium and camphor to be placed over the pit of the stomach and the lower part of the chest.

5th.—Much better, but weak; the pains in the chest are removed.

7th.—A little better; a slight vesicular eruption has appeared on the back of the left hand; she fainted twice yesterday. I added to the mixture one ounce of spirit of nitric æther, and in other respects I continued the same treatment.

24th.—She looks quite another person; walks firmly, and only feels the pains and noises in the head at rare intervals; for the last few days her whole skin is in a state of moist perspiration.

June 12th.—The patient is very well; the pains in the head have almost entirely left her; she feels well, and has grown stouter.

While under the influence of the same treatment the patient is well, but when she leaves it off there is a slight return of the same symptoms, thus affording evidence that, in this case at least, it was to the treatment and not to time, or to the unassisted operations of nature, that the patient owed her restored health.

In conclusion, I feel bound to state, that by combining the use of sedatives with that of other remedies, it is possible to remove any amount of pseudo-narcotism, and as this treatment, with short intermissions, may be continued for months, it is well calculated to allay some of those tedious ever-occurring infirmities which beset women at the last great crisis, and particularly that pseudo-narcotism which, as I have already stated, sometimes causes them to be falsely accused of consoling the decline of life by an intimacy with Bacchus—a

gentleman not generally admitted into ladies' society. To ladies—to all women, this is, of itself, a matter of serious importance; but the beneficent use of sedatives will be fraught with even a higher import to the meditating medical philosopher. By their judicious, more frequent, and more continued use, may they not be made more available than hitherto in withstanding the overstimulating effects on the nervous system of our present civilization, arresting in its bud that tendency to mental derangement which, if statistics are to be depended upon, occurs more frequently in women than in men? There is a yellow poppy which expands its gaudy petals alike in arctic regions and in sultry southern climates, thriving in both extremes of temperature, as if intended to point out the utility of sedatives to man by the constancy of their companionship, whatever latitude he may inhabit.

8, York Street, Portman Square.

Provincial Medical & Surgical Journal.

WEDNESDAY, JULY 23, 1851.

In our remarks upon the British Medical Fund, in a recent number of the *Journal*, we inadvertently omitted any distinct allusion to the sickness fund as a branch of the proposed scheme. We have been reminded of this omission by Mr. Daniell, and we have no hesitation in recognizing the justice of his complaint, though we certainly considered that "sickness" and "premature old age" should be regarded as synonymous terms; and at the very commencement of the article alluded to we stated, that "The British Medical Fund is set on foot to afford to the provident member of our profession the best means of insuring himself against *premature old age*, and his family from the misery and want, which his early death, (before sufficient time has elapsed to allow proper provision,) so often forces upon them." It cannot, therefore, be said that we ignored the principle of insurance against sickness; but we freely confess that in our summary of the advantages held out by the British Medical Fund, we omitted all allusion to the "sickness fund."

Mr. Daniell will find, by examining our leading article, that we anticipated him in every point in which he shows the want of similarity between the two Societies, and therefore we have nothing to remark on that score, but we have thought it right to do justice to the projectors of the British Medical Fund, as far as lies in our power, by admitting that the principle introduced by them, of insurance against sickness, did not receive that full attention from us, which it deserves.

We do not know that there is any provident society in existence, which insures against sickness, unless under circumstances in which a full supervision can be exercised by its regular officers. But in this we do not see much difficulty, as there is very rarely a case in which a medical man, suffering from disease, is unattended by a brother practitioner, and he would always gratuitously certify as to the state of the invalid, which would be a check against any chance of imposition upon the funds of the Society. It is scarcely probable that any man of education should be so lost to all feelings of honour as to make an attempt of the kind we allude to, but it is better that temptation should be removed, than that we should have to mourn over so melancholy an instance of dissimulation and fraud.

With the superintending care, which we have no doubt will be exercised, we think the "sickness fund" ought to be warmly supported by the profession; and in this department there is certainly no rivalry, as there is no other institution offering the same provision. We have not been able to obtain from Mr. Hawtayne, any explanation of the details of the working of the plan, but we have not the slightest doubt that all precautions will be taken which are afforded by the well-known scientific acquirements of Mr. Neison.

The pressure of other matters, including the proceedings of our Branch Meetings, which have been more than usually interesting, will prevent any further allusion to the subject, but we must repeat our regret that we should, though only in appearance, have neglected the claims of so valuable a provision as the sickness fund promises to be.

Proceedings of Societies.

LANCASHIRE & CHESHIRE BRANCH.

The fifteenth annual meeting of this branch of the Association was held at the Town Hall, in Manchester, on Wednesday, the 25th ult. The attendance of members was large, including Thos. Turner, Esq., of Mosley Street, Manchester, the President for the current year; John Hatton, Esq., Manchester, the Hon. Secretary; Dr. Eason Wilkinson, Dr. F. Renaud, Dr. C. Bell, Manchester; Dr. W. H. Duncan, (the

retiring President) Liverpool; D. Noble, Esq., H. M. Williamson, Esq., John Windsor, Esq., J. Kenworthy, Esq., J. B. Harrison, Esq., W. J. Wilson, Esq., E. Lund, Esq., Jas. Whitehead, Esq., J. Walsh, Esq., — Somers, Esq., — Skinner, Esq., J. Woodward, Esq., J. Hancock, Esq., R. H. M'Keand, Esq., J. Roberton, Esq., W. Smith, Esq., G. M. Harrison, Esq., R. M. Mann, Esq., jun., S. Crompton, Esq., of Manchester; John Sharp, Esq., Warrington; John Nottingham, Esq., Liverpool; E. W. Lowe, Esq., Congleton; A. D. Dunstan, Esq., Holmes Chapel; George Dagliesh, Esq., Wigan; Ellis Jones, Esq., Liverpool; George Sumner, Esq., Lymm; Thomas Fawsitt, Esq., Oldham; William Kershaw, Esq., Royton; H. Halkyard, Esq., Mosley; J. M. Robinson, Esq., Bolton; William Hunt, Esq., Warrington.

Dr. Duncan, the retiring President, was unable to attend at the commencement of the proceedings, and therefore, on the motion of Mr. Hatton, Mr. Turner, was called to the chair.

The Chairman in opening the proceedings, said, Gentlemen,—in rising to commence the business of this, our annual meeting, it is my duty to make a few prefatory remarks upon the object for which we are met, and the duties which seem to demand from us urgent attention at this time, in connexion with the important profession to which we belong. I regret that the retiring president, Dr. Duncan, has not been able to meet us to close the proceedings of the year, for I have very little doubt if he had been he would have made some retrospective remarks with respect to our profession; the more so, as I believe he was prevented attending our last meeting, by a serious bereavement occurring in his family. I think it the duty of each President in rotation to make some retrospective remarks, because the object of meetings of this sort I conceive to be one of great and abounding interest amongst the profession. To medical men in the two important counties of Lancashire and Cheshire, such a meeting as this cannot fail to be not only extremely important, as bringing them together and thereby causing good will and good feeling to exist amongst the members of the profession; but it is likewise extremely important as tending in no inconsiderable degree to have the effect of enhancing the dignity of our profession. (Hear.) I should like to know what profession ought to sustain a dignity higher than our own? And why is it that the dignity of our profession has in any measure suffered in public estimation? (Hear.) If we scrupulously inquire into the subject, we may refer to the undignified conduct of many persons connected with us in its practice; and a meeting of this kind is important, for men who have acted otherwise than as gentlemen will not, from shame-facedness, show themselves on occasions like this. By meeting in this way annually, we secure a further advantage, for we are enabled to talk face to face with men we had become acquainted with by their writings or their fame, but whom we desire to become acquainted with personally. This is a matter of deep interest and advantage; and, therefore, I congratulate you most sincerely upon the meeting taking place again this year. It will be important that we should review some of the subjects connected with our profession, that have since our last meeting demanded our strict attention, not only as connected with ourselves, but as connected with the community, and as connected with the profession to which we belong. I shall not occupy your time now by dilating upon those subjects, as I shall reserve some remarks for the meeting we shall have in the afternoon, which will be of a more convivial kind, but at the same time not apart altogether from matters of business. But there are three or four points of so much interest, that I should ill discharge the duty of President were I not to advert to them on this occasion. If we take a review of the proceedings of the medical profession during the last twelve months we shall find the harvest has not been a very productive one, either in discovery or in the application of the discoveries which had been previously made. But there is a rich harvest in this—there have been corrections of many errors which had been antecedently indulged in, and which, if continued, would have been detrimental to medical practice. I am quite certain that there has been a great error in going to extremes in our profession. Although it is a tendency of the human mind to fall into extremes, yet you well know that extremes are always dangerous, and we cannot do better for our profession than inculcate on its members this one point as a law:—avoid extremes in every way that you can possibly, as dangerous quicksands, and as leading to error and to destruction of a most formidable kind. Let us just see what the application of extremes would be in connexion with our profession. Look at extremes of opinion. How many minds are blinded to facts that might otherwise be obtruded on them if not for prejudices entertained by them in favour of peculiar views. Look at extremes of opinion! One set of men believing that everything is of an inflammatory kind, and acting in practice in accordance with that view; on the other hand, men believing that everything is of an asthenic character, giving medicines to sustain health and strength which may be considered as sustaining disease, and leading to death. Look at extremes in practice! One set of men all mercury, another set of men all iodine, another set of men all opiates, another set of men all bleeding, another set all blistering, another all purging. Now, this exclusive practice must be undignified, must tend to undignify the profession, and cause it to sink toward the pale of empiricism. Extremes have been especially carried out in the two systems of practice, homœopathy and hydropathy. Now, it is not consistent, nor is it policy, on the part of our profession, to pooh pooh either the one or the other. There is no system which has not in it wheat as well as chaff, and the great duty which devolves upon us is to endeavour to separate the one from the other. If we were called upon to define homœopathy, we might speak of it, perhaps, as a system of curing disease without physic, throwing, therefore, the entire power into the hands of the dietist, and into the hands of the individual who would recommend exercise. Now, if we take hydropathy, it is

carrying the practice of cure by the agency of water to an extreme; but what man amongst us is there who does not place great confidence in the use of water, hot and cold, and therefore it is a libel on the profession to suppose that we are not constantly employing the means which hydropathists employ for the cure of disease. But we proceed honestly I trust (hear); we proceed unexclusively I trust, and adopt those means in accordance with circumstances according as may be suggested, either the one or the other, and we apply them upon settled principles of medical science. Look at medical conduct! Are there not extremes constantly observed tending much to undignify the profession, tending to render it obnoxious to the public, detrimental to its best interests, and in every way unsatisfactory to men of honourable minds. One set of men, for example, will endeavour to gain practice by a conduct anything but what would be expected from a gentleman—the cajoling of patients, or assuming a roughness of manner; all this may be supposed to be taken by some individuals for profound talent. Then, on the other hand, quite as despicable, and quite as much opposed to the dignity which should attach to the profession, is the obsequiousness which we meet with amongst the members of our profession, yielding up their opinion to their patients upon every little circumstance in which it may seem to be opposed to their views and wishes. This reminds me forcibly of an anecdote which I have read of one of the physicians of the Court of George III. In a case of sickness His Majesty suggested to the physician "a little ice would be exceedingly agreeable to the patient." "Yes, and please your Majesty, it would be most delicious, and the patient shall have some ice." In the course of a few minutes His Majesty said,—"But on reconsidering the subject I think it would be very cold." "Yes, your Majesty, it would be exceedingly cold, but we will obviate that by heating it!" (Laughter.) I will not detain you longer, as there are other matters of business to come before us in our meeting. We shall meet again in the after part of the day, when many subjects will be brought on for conversation and useful discussion; I shall, therefore, sit down, in order that the business may proceed according to the routine the Honorary Secretary will point out to us.

Mr. HATTON then read the report of the Council for the past year, as follows:—

Report of Council.

The Council of the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association congratulate the members upon having attained their 15th anniversary celebration, after a career which they deem to have been successful and prosperous.

An explanation is due from the Council to this meeting, respecting the present assemblage taking place in Manchester, and not in Preston, as was determined upon at the annual meeting held in Liverpool last year.

The Council had reason to believe, from information which they received, that but little interest in the affairs of this Association existed in Preston, and that but few members of the profession belonging to that locality would be likely to co-operate in giving *eclât* to the annual gathering. Under these circumstances, the Council exercised a privilege conceded to them by the rules, and resolved to meet in Manchester, conceiving that nothing could be more detrimental to the interests of the Branch than a sensible falling off in the number of persons attending their anniversary meetings, and in a consequent diminution in the spirit with which the celebration takes place. In this view of the case, they entertain a strong conviction that it would be well to alternate their meetings constantly between Liverpool and Manchester, as in either of these two great centres of population a successful assemblage of the profession could at all times be reasonably looked for.

The last year's proceedings of the Branch have not been characterized by any active proceedings relative to general medical polity; the Council have yet seen with pleasure the course pursued by the Central Council of the General Association with respect to the long-pending and much agitated question of Medical Reform. This meeting will doubtless concur in the propriety and judiciousness of the memorial presented by them to Sir George Grey, a copy of which was published in the ninth number of the *Journal* for 1851.

The members of the Branch will have been gratified, during the past year, in observing that some of the grievances long complained of by their brethren in the army and navy have been removed. The Council are persuaded that much of the attention which of late years has been paid, both by the Government and other authorities, to the medical profession, has resulted, in great measure, from the spirit of union and organization which latterly has developed itself within its ranks.

It is a subject of gratification, moreover, to have noticed that recently the Legislature has enacted a law restricting facilities for the sale of arsenic; a just measure of medical police and of humanity, which the profession must especially appreciate.

The Council and members have to lament the deprivation which the Branch has sustained during the past year in the death of three of its most estimable associates, Mr. Thorpe, Mr. Dorrington, and Mr. Lomas, all of Manchester. Mr. Thorpe was long recognised as a most able and useful member of the profession, and he took an active and sustained interest in the proceedings of this Branch. Mr. Dorrington had become one of its members only the year preceding his decease; but from his superior talents and remarkable *esprit de corps*, the Council lament his loss to the Branch, as one that will not speedily be repaired. Mr. Lomas, too, was a rising ornament to the profession, being a gentleman that was deeply conversant both with medical and general literature, as well as practically skilled in the exercise of our art.

Although these losses have been experienced by the Branch, the Council have yet to congratulate the members upon a considerable accession to their effective strength, an addition of nearly thirty members having been made since the last anniversary. The Honorary Secretary, moreover, has within the last twelve months issued no fewer than six hundred circulars to members of the profession, setting forth the objects and the aims of the Association. Experience, however, shows

that such a proceeding does but prepare the way for an effective canvass of a more personal and immediate nature; the Council, therefore, hope that members will exert themselves individually to increase the strength of the Lancashire and Cheshire Branch, which, with moderate energy, would form the most powerful one in the kingdom, a fact that is sufficiently obvious when it is considered that the circuit of its operations comprises not only the two largest of provincial towns, Liverpool and Manchester, but also a multitude of other places remarkable for their extent of population; all these being virtually brought into close contiguity by the ramification of the several railways.

There is great reason to anticipate that the annual meeting of the General Association will, next year, be held in Manchester; if so, it will be for this meeting to determine whether it may not be desirable to suspend for one year the customary assemblage of this Branch, as many members entertain the very reasonable idea that the success of the two meetings in the same locality may be somewhat problematical.

With regard to the finances of the Association, the Council have to report that at the last annual meeting there was a balance of £1. 5s. 1d. in favour of the Association. Since that period the recipts have amounted to £12. 2s. 6d., and the expenditure for printing, advertising, postage, and incidental expenses, to £8. 18s. 10d., which leaves a balance of £4. 8s. 9d. in hand for current expenses.

Moved by J. KENWORTHY, Esq., of Manchester, seconded by E. W. LOWE, Esq., of Congleton, and carried,—

"That the Report of the Council now read be adopted, and transmitted to the Secretary of the Provincial Medical and Surgical Association for publication in the *Journal*, together with the proceedings of this meeting."

Mr. DAGLEISH, I move,—

"That the next anniversary be held at Liverpool, and that Robert Bickersteth, Esq., Surgeon, of Liverpool, be appointed President, and James Black, M.D., of Bolton, and Richard Flint, Esq., Surgeon, of Stockport, Vice-presidents, for the ensuing year."

I quite approve of it: I think the Council exercised a wise discretion in fixing on Liverpool, as being so large a town.

Mr. HATTON read that portion of the Report which has reference to the meeting of the Parent Association.

The CHAIRMAN: The point for consideration is, then, whether we shall have a meeting next year or not, owing to the fact of the meeting of the Parent Association being held in Manchester. Of course it is open to discussion.

Mr. NOBLE: I beg to suggest that the resolution relating to the subject shall be conditionally worded, that is to say, if it be determined that the next anniversary meeting of the Parent Association shall be held in Manchester, that in such case the meeting of the Branch shall be postponed to the succeeding year; but as there is no resolution of the Parent Association that it will meet here next year, we cannot, particularly in a resolution, notice a view that may not be realized.

The CHAIRMAN: I think it is all but announced.

Mr. NOBLE: I think so too, but it should not be put into the resolution.

The CHAIRMAN: Should there, then, not be a meeting of the Branch for two years?

Mr. NOBLE: That is my proposition.

The CHAIRMAN: Your proposition would say, conditionally if the Parent Association should hold its meeting in Manchester. But even if it be held in Manchester, is it a sufficient reason why we should defer having our annual meeting? You are to remember one thing, that if the annual meeting of the Branch fell in Manchester, there would be sufficiant reason for deferring it, but it is to be held in Liverpool, and that is a consideration. All the members of the Branch are not members of the Parent Society, and those who are not would like to have a meeting perhaps on that occasion.

Mr. NOBLE: It will, perhaps, simplify the proceedings, if we pass the resolution as it stands, and then have a separate resolution saying *when* the annual meeting shall be celebrated, otherwise we shall be discussing separate points. The resolution as it stands may be passed, however it is determined, and the succeeding resolution may determine *when* it shall occur.

Mr. FAWSITT: It will be well to pass the resolution as it stands, and leave it to the Council to consider the subject, and to call the meeting by sending a circular to each member.

The CHAIRMAN: You might word it thus:—"That the next meeting of the Branch be held at Liverpool," and that will not fix us to next year, or the year after.

Mr. NOBLE: It does not fix the time?

The CHAIRMAN: No.

Mr. NOBLE: We might pass the resolution as it stands, and a resolution such as Mr. Fawsitt names might follow.

Mr. FAWSITT then seconded the motion which Mr. Dagleish had proposed.—It was put and carried.

Mr. KERSHAW: Is it necessary to read the names of the members of the Council?

Mr. HATTON: I believe it is necessary, for, according to rule, they all go out at each annual meeting.

Mr. KERSHAW: I have great pleasure, then, in moving,—

"That the following gentlemen constitute the Council and officers of the Association for the ensuing year:—*Officers and Council for the Year* 1851 *and* 1852.—Thomas Turner, Esq., Surgeon, Manchester, *President;* Richard Broadbent, Esq., Surgeon, Altringham, H. H. Broughton, M.D., Preston, *Vice-Presidents:* John Hatton, Esq., Surgeon, Manchester, *Honorary Secretary*; Samuel Crompton, Esq., Edmund Lyon, M.D., Thomas Radford, M.D., George Southam, Esq., W. J. Wilson, Esq., Daniel Noble, Esq., Manchester; Edward Batty, Esq., Robert Bickersteth, Esq., Joseph Dickenson, M.D., Ellis Jones, Esq., Sir Arnold Knight, M.D., R. W. Scott, M.D., Liverpool; Abraham Wood, Esq., Rochdale; J. A. Pearson, Esq., Woolton; Thomas Fawsitt, Esq., Oldham; John Sharp, Esq., Warrington; Richard Flint, Esq., Stockport; George Dagleish, Esq., Wigan; J. M. Robinson, Esq., Bolton-le-Moors; Richard Hindle, M.D., Whalley.

Officers-elect for 1852 *and* 1853.—Robt. Bickersteth, Esq., Surgeon, Liverpool, *President;* James Black,

M.D., Bolton-le-Moors, Richard Flint, Esq.; Stockport, *Vice-Presidents;* Ellis Jones, Esq., Surgeon, Liverpool; John Sharp, Esq., Warrington; J. M. Robinson, Esq., Bolton, *Local Secretaries.*"

Mr. SUMNER: I second the resolution.

The resolution was put and carried.

Mr. FAWSITT: It has been suggested that I should move a resolution that the next meeting be conditional in some measure on the great Association being held in Manchester next year, or that it be, in some measure, left to the discretion of the Council.

Mr. HATTON: I may state that the Council have power in one of the rules, which I had better read, to alter not only the time but the place of meeting.

Mr. NOBLE: I second Mr. Fawsitt's motion, and I think it necessary to pass it because, although the Council have power to alter the time and the place of meeting, the rule yet insists that the meeting shall be annual. I think unless this meeting of the Branch authorise an actual postponement for a year, the resolution as it stands will not give that authorization. In that view of the case Mr. Fawsitt's resolution is quite necessary, and I second it with great pleasure. Of course the object entertained by the Council in agreeing to some such rule as this, or in thinking it proper to bring the subject before the meeting, as expressed in the report, is, that two meetings might not be likely to succeed in the same locality. And when we consider the engagements of medical men, and the inconvenience of going from home, or even though at home, of giving the greater part of a day to public matters, though professional, we should not tax the time, and in a minor degree the purses, of the members of the Association too much, particularly as the result of a failure in attendance, as compared with previous years, would be rather to damage the *eclât* which otherwise attaches to meetings of the Branch. I think the members generally will take the same view of the case as I have done, and will agree to leave it to the Council to say whether they will think it right to have an anniversary next year, if the Parent Society meet at Manchester. I think Mr. Fawsitt's resolution will meet the exigency. Mr. Noble then wrote out the following resolution which was proposed by Mr. Fawsitt, and seconded by himself, and carried:—

"That the question of holding an anniversary meeting of this Branch next year rest with the Council, who will consider how far such meeting may be expected to be successful, in case the General Association in 1852 meet in Manchester."

Mr. FLINT: I have much pleasure in accordance with the tenor of the resolution, to move,—

"That the thanks of this meeting be given to the retiring President, W. H. Duncan, M.D., Liverpool; and the Vice-Presidents, Thomas Radford, M.D., Manchester, and James Edwards, M.D., Chester."

Mr. ELLIS JONES, of Liverpool, seconded the motion.

The CHAIRMAN: This is a resolution which we trust all accord in, and it is scarcely necessary for me to put it to the vote. I believe it is a matter of deep regret that Dr. Duncan could not attend the anniversary meeting of last year, through the occurrence of a domestic calamity which prevented him. I am sure you will carry it with acclamation, (Cries of—all, all,) but I will put it to the vote.—Carried unanimously.

Mr. NOBLE: Mr. Chairman, I rise to move a resolution which the Honorary Secretary has been exceedingly anxious should not be moved at all. However, I am perfectly certain that in the opinion which he entertains upon the subject he stands alone; and making every allowance for his modesty, I think it would be an injustice if the resolution which I have taken upon myself to move, were not adopted by the present meeting. (Hear.) I, probably, am the most suitable person to move it, because I incline to the opinion that I see as much, probably more than any other member of the Council, of the extraordinary zeal and energy, and activity of our Honorary Secretary, Mr. Hatton, and it is a vote of thanks to him that I now move. (Applause.) It is a frequent remark, and I believe a perfectly just one, and all who have had experience in public matters, however humble their character, will have observed its truth, that the success of all combinations depends essentially upon the Secretary. (Hear.) Without an influential Secretary, we may have an excellent President, an admirable Council, the best possible of members, but still success will never attach to our operations. In Mr. Hatton, I am sure we have all those conditions fulfilled; and therefore I feel that every member present will be anxious to second the motion which I now make,—

"That the best thanks of this meeting be given to Mr. Hatton, our most zealous, energetic, and efficient Honorary Secretary."

Dr. WILKINSON: I beg leave to second the resolution of Mr. Noble, in which I most heartily concur.

The CHAIRMAN: Before putting this resolution to the vote, I may perhaps be allowed to make a few observations upon my knowledge of Mr. Hatton's zeal and interest for the well doing of this branch. Having been brought into contact with him antecedently to my taking this chair, I am quite sure he is the steam engine of the branch. The Council may be the mechanical part of it, but he is the steam engine, and I am sure he will keep us afloat. So long as Mr. Hatton holds the appointment of Secretary in this institution I feel certain it will last and continue; if it were to lapse into other hands I might have some doubts about it; he is therefore entitled to the warmest thanks and well-wishes of the members of the branch, and I will put the resolution which has been moved.

The motion was then carried uannimously.

Mr. WINDSOR: I have much pleasure in moving,—"That the thanks of this meeting are especially due to the Council for their services during the past year." Though the greatest merit may be due to Mr. Hatton, I have no doubt the Council has also its share.

Mr. HALKYARD: I have great pleasure in seconding the resolution which Mr. Windsor has just moved.—Carried.

Mr. HATTON then announced that it was the proper time for nominating new members. The names of certain gentlemen were given in and they were elected

pro formâ. He then said, I have received a letter from Worcester, from the Central Council, requesting the attention of the members to the memorial recently sent to Sir George Grey, from that body. I dare say most gentlemen have read the memorial, but I will read it again. Mr. Hatton next read a resolution which had been passed by the North-Wales Branch.

Mr. Noble: I have just drawn up a resolution which probably will meet with general concurrence. It is this—not precisely after the text of the North-Wales one, nor altogether going so far as it does, but therefore more likely to secure unanimity,—

"That this branch concur in the general spirit of the proposition, contained in the memorial presented to Sir George Grey, by the Worcester Council, in April, 1851."

I say general spirit of the proposition, because I apprehend if the details are thoroughly understood, there will be some little difference of opinion with respect to some of them. I confess, I do not concur in them all. I see a proposal contained in the memorial that the right to elect the Council of the College shall rest with all the members, and not with the fellows; and that is a condition of things that will not be at all likely to be realized. It is going beyond what most medical reformers have sought, and beyond what is necessary to a satisfactory and conciliatory adjustment of the question. (Hear.) I have felt during the long agitation respecting the College, that the most active opponents of the Charter of 1843, have always exhibited a disposition to act justly, and in a conciliatory spirit. We should continue in this disposition. If we adopt any resolution which is *ultra,* we shall defeat our own purposes, and I for one would not go with the letter of the memorial which seeks for the elective right to be vested in the whole body of *members;* I would leave it with such as are fellows. At the same time I think it will be undesirable that we should embody in a formal resolution to be published, the fact of the difference of opinion existing, especially as the demand for the elective right to be vested in the members has emanated from the Central Council; and it would not be politic or good taste to bring out the fact of disunion in our ranks. It is to obviate that, without pledging ourselves to what we do not in our consciences approve, that I would prefer a resolution such as I have drawn up, expressing concurrence in the general spirit of the proposition. While that does not pledge us to the ulterior suggestions or propositions of the memorial itself, it does not bring the fact of our disunion before the professional public.

The Chairman: It does not bind us to any details.

Mr. Noble: Exactly. If this resolution meet with the concurrence of the meeting, I shall be happy to move it.

Mr. Flint: I have great pleasure in seconding the proposition of Mr. Noble. It appears to be penned in that judicious and discreet style for which Mr. Noble is so signalized, and inasmuch as it will attain the object for which the memorial is presented to Sir George Grey, it will be politic in us to avoid every sentiment which might lead to anything like disunion. I have great pleasure in seconding the resolution.

The Chairman: We are quite open to hear the remarks which any gentleman may choose to make.

As all were silent, the motion was carried without discussion.

Mr. Standring, apothecary, of Manchester, was introduced by Mr. Hatton, and laid before the members of the Society a petition to the House of Commons in favour of the Bill for regulating the practice of pharmacy by compelling an examination in it before persons can be admitted to practice.

Mr. Standring said it had been suggested that there would be many members of the profession present, and it might be well to get an expression of opinion from them on the matter.

The Chairman: You have not laid down any law as to what reforms you require.

Mr. Standring: The bill is here. It is simply to compel an examination before persons commence the practice of pharmacy.

The petition was then handed round the room, and received several signatures.

Mr. Hatton: I believe this terminates the business part of the proceedings, and now is the time, if any gentleman has any papers to bring forward, to have them read. I may state that Mr. Wood has been kind enough to bring some surgical instruments that are of beautiful construction, and no doubt of an admirable nature. The new wing of the Infirmary has been built upon the best and most approved principles, and Mr. Fernley, one of the house-stewards, has been kind enough to say that he will go round at two o'clock with any gentleman who may take an interest in seeing the most admirable improvements in construction, ventilation, &c. I have never seen it myself, I shame to say, though living in the town, but I believe it is well worth seeing.

The members then proceeded to read various papers on professional subjects.

In the evening the annual dinner took place at the Albion Hotel, Piccadilly, Mr. Turner presided, and all the gentlemen already named were present, with the addition of Surgeon Young, 28th Regt., and the Rev. Mr. Bawdwen, the chaplain at the Royal Manchester Infirmary.

BATH AND BRISTOL BRANCH.

The Bath and Bristol Branch of the Association held their Annual Meeting at the Bristol Medical Library, on Thursday, the 26th of June. The following members were present:—Messrs. Bally, J. Barrett, Bartrum, Wm. Davies, M.D., George, King, Mc Dermot, M.D., Norman, Soden, Stone, and Tunstall, M.D., of Bath; Wm. Budd, M.D., Thos. Green, W. James, M.D., Mayor, Morgan, Nield, Prichard, Ruddock, Sleeman, Sheppard, and Symonds, M.D., of Bristol; Brittan, M.D., Colthurst, Goodeve, Lancaster, Smerdon, and Swayne, M.D., of Clifton; Allen, of St. George's; Cockey, of Frome; Collins, of Chew Magna; Crang,

of Timsbury; W. C. Fox, M.D,, of Northwood's; Macey, of Westown; Ogilvie, of Stapleton; G. Vicary, of Warminster; Washbourne, of Corsham, and Woodforde, M.D., of Taunton.

The retiring President, Dr. Hodges, having sent a note expressive of his regret at being unable to attend, Dr. Symonds took the chair, and called upon

The Bristol SECRETARY to read the notice of the meeting, after which,

The Bath SECRETARY read the minutes of the last annual meeting, and, in connection therewith, a letter from Sir Charles Hastings, thanking the Society for their kind congratulations on the honor then recently conferred upon him.

Dr. SYMONDS then commenced his own proper duties as President, by reading to the members an address, which was much applauded for its truthful delineation of the past and present state of the medical profession, as also for the playful, but sarcastic humour, with which it treated the several heresies of the day. (See page 393, where the address is printed in full.)

Mr. COLTHURST then read the following report:—

Report of the Council of the Bath and Bristol Branch Association, June 26, 1851.

The Council, in presenting to the members of this Society the report of their proceedings during the past year, cannot but congratulate them on its continued prosperity. Ten years have now elapsed since the union between the originally separate branches of Bath and Bristol, and should any one suggest the question—*Cui bono?* your Council have a pleasure in referring to the feelings of individual members for a response. The goodly array of names on the list of members is usually referred to as a proof of prosperity and continued interest; your Council would rather point to the large attendance at the quarterly meetings as an assurance of this. The occasional exchange of hospitalities, no less than the interchange of professional knowledge, consequent upon these meetings, tends much to break down the jealous asperities which have been, too often deservedly, the stigma upon us. The Council refer with pride to the many friendships that have grown up under the wing of your periodical re-unions, as a stimulus to others no longer to hold themselves aloof, but merging individual notions, to come and join them heart and hand, so that your Society may present a bolder and more determined resistance to everything that is derogatory to the character of the profession. The very valuable practical information gained by you on the much disputed subject of ovariotomy is another illustration of the value of your Society, so much so, that it will be somewhat interesting to review the fruits of the past in this respect. It will be recollected that, in September, 1849, Mr. Crouch, of Bruton, narrated the successful removal of a large ovarian cyst, which seems to have aroused a special attention to the subject, for we find that on September 19, 1850, Dr. Woodforde, of Taunton, read an extremely interesting paper on the successful removal of a similar mass of disease by his colleague, Mr. Cornish, at their County Hospital; and in the December following, Mr. Wilson, of Bristol, gave his admirable paper containing the details of four cases of ovarian tumours which had been operated upon by him, three of them successfully. Independent of this subject, the Society is also indebted to Dr. J. G. Swayne, for his exceedingly interesting case of polypus uteri; to Mr. Hunt for the exhibition of a very beautiful specimen of a very rare disease of the mucous membrane of the stomach, described by Rokitansky in his "Pathological Anatomy," and to which the author has applied the distinctive name of "surface mamellonnée; to Dr. Burne for his very excellent and practical paper on "Intestinal Obstructions;" and also to Mr. Prichard for his succinct and well-arranged report of some "Cases of affections of the Cranial Nerves." All of these papers have been published in the *Journal*, so that absent members have had, in some degree, an opportunity of deriving benefit therefrom. But your Council cannot dismiss the consideration of this subject, without a reference to the great amount of practical information drawn forth from various members during the discussions arising out of the papers on ovariotomy and intestinal obstructions; information and results of experience which otherwise, it is not too much to assume, would never have been given to the world, but which, nevertheless, every one who is occupied with the anxieties of a professional life, must know how to value.

Your Council wish also to advert to the success which has attended the memorial addressed by you, at your last anniversary, to Lord John Russell, as first Lord of the Treasury, in respect of the honors proposed by the government to be conferred on distinguished medical officers of the Army and Navy, as its influence in connection with other similar ones, has been gracefully acknowledged by yielding its prayer and conferring the military, instead of the civil order, on those who had so richly merited it. Nor would your Council leave unnoticed the passing by the Legislature of the Arsenic Bill, for the promotion of which, the petition agreed upon by you in March last, was presented by Wm. Miles, Esq., M.P., for East Somerset. Your Council feel especially bound to congratulate you on its success, as it has mainly depended upon the efforts made by your Central Association, ably carried out by the activity and zeal of one of your associates, Dr. Tunstall. Your local Council have received a request from the central one that a resolution, approving of the memorial lately presented by them to Sir George Grey, in respect of some recent resolutions of the Royal College of Surgeons of England, may be laid before you for adoption. The central Council consider that these resolutions, although not embodying the whole of what they have been accustomed to ask for, contain so many concessions on the part of the Council of the College, that it would now be more graceful to be satisfied therewith, and at once, by consentaneous action, to put a stop to the necessity for further consideration of a subject which has long been looked upon by very many as stale, flat, and unprofitable. In order, however, that you may fully understand what is asked of you, it may

be as well to read to you the proposals of the College, passed at their meeting on the 19th and 24th of March last. They are—

1st.—"That in the opinion of this Council, such part of the charters and bye-laws of the College as restrict the eligibility to the Council to Fellows residing and practising surgery within five miles, by highway or road from the General Post-office, in St. Martin's-le-Grand, should be abrogated.

2nd.—"That in the opinion of such Council, such part of the charters and bye-laws of the College as restrict the eligibility to the Council to Fellows not having, during the five preceding years, practised midwifery or pharmacy, and require a certificate thereof by three Fellows, should be abrogated; and that instead thereof, a certificate by three Fellows, and a declaration by himself, that the person nominated to be ballotted for as a member of the Council does not practise as an apothecary be required.

3rd.—"That it is the opinion of this Council that the medical qualifications of those about to engage in the practice of surgery, or in general practice, should be tested by the Royal College of Physicians.

4th.—"That the Council of this College are prepared to form and superintend a Board of Examiners in midwifery, or to co-operate with the Royal College of Physicians in the institution of examinations for testing the qualifications of practitioners in midwifery."

Upon the publication of these resolutions a meeting of the Central Council was held, April 5, 1851, when it was resolved—"That the Council hereby express their gratification that the Council of the Royal College of Surgeons have adopted a series of highly conciliatory resolutions, which go far to satisfy the requirements set forth in the memorial of this Association, which was presented to Sir George Grey, in May, 1850; and they trust that, by mutual concession of both parties, there is a prospect of a speedy and satisfactory termination of the long agitated question of Medical Reform." The central Council request your support of the memorial presented by them to Sir George Grey, and which will be found in the *Journal* of April 30, 1851.

Whilst heartily agreeing with the central Council in their congratulations upon the prospect of a speedy settlement of so troublesome a matter, your Council think it right to point out to you that there seems to be no reference whatever to the Apothecaries' Company, a body to whom the older members of the profession, well remembering its condition a few years since, are always disposed to award the meed of praise; and who, even now, amidst all the throes and upheavings of malcontents, seem desirous of proving, that if the *elite* of the profession are talking of reform, they are absolutely carrying it into operation by the promotion of an improved education; and they have, in accordance with that determination, issued a series of resolutions that would do credit to many of our Universities, and which are published at length in the *Journal* of May 28, 1851.

These, it must be acknowledged, form a move in the right direction, and must ultimately tend, by whatever corporation they are carried out, materially to elevate the social position of the medical profession. And your Council strongly recommend you, in adopting the resolution proposed by the central Council, to express your sentiments:—that much as you approve of the manifesto of the Council of the College of Surgeons, so far as it goes, you are decidedly of opinion that no reform of the medical corporations can be beneficial to the profession which does not require them to keep up to a respectable standard, the literary, as well as purely professional examination of the whole of its members.

Your Council would also suggest to you the consideration of the propriety of a resolution in favour of the Royal Colleges of Edinburgh, who have recently, in so proper a spirit, shown their desire to remove from them the stigma of retaining among their Fellows gentlemen who call themselves physicians, practically repudiating the study of pathology, and treating symptoms only by doses of an inappreciable character.

Your Council are again emboldened to urge upon your attention the claims of the Benevolent Fund of the Association. They are most anxious to forward the progress of every charitable institution, and in this spirit are desirous of upholding the British Medical Fund, which was so ably explained to you by Mr. Hawtayne; but at the same time they are bound to watch carefully over your own *protegé*, lest the efforts made to advance a friend, may ultimately destroy your own intentions.

Your Council, before resigning their stewardship, have to report that, in accordance with the resolution passed at the last anniversary, they have issued 108 printed lists for the purpose of the ballot. Of these only 34 have been returned to the Secretary, four of which are turned aside, as having more than 27 names; and three because they have no attestations or signatures. An examination of the remaining 27 shows that the following gentlemen are elected as councillors:—

Bath.—Messrs. W. F. Bally, W. J. Church, Wm. Davies, M.D., R. F. George, Race Godfrey, G. Norman, J. Ormond, John Soden, and James Watson, M.D.

Bristol.—Messrs. Wm. Budd, M.D., H. Clark, J. B. Estlin, H. H. Fox, M.D., W. F. Morgan, Chas. Smerdon, T. L. Surrage, J. C. Swayne, and Wm. Trotman, M.D.

Rural.—Messrs. Geo. Allen, A. Adye, Wm. Colborne, Jas. Crang, Wm. Coates, F. Flower, Wm. Kay, G. S. Ogilivie, and Geo. Vicary.

Mr. Green moved, and Mr. Goodeve seconded, the adoption of the report, which was carried unanimously; as also was the resolution moved by Mr. Crang, and seconded by Mr. Ogilvie, conveying the best thanks of the meeting to Dr. Hodges, for his zealous and efficient services, as President, during the past year. So, also, a similar resolution in respect of the retiring Council and Honorary Secretaries, was moved by Mr. Sleeman and seconded by Dr. Swayne. Mr. Bally moved, and Mr. Nield seconded the proposition, that Geo. Norman, Esq., be President-Elect, which was received with much acclamation,

Mr. George moved, and Dr. Woodforde seconded, the resolution, that Messrs. Colthurst and Bartrum be

re-elected Honorary Secretaries, which was carried unanimously.

Mr. Colthurst acknowledged the compliment which had been paid to his colleague and himself, by the too flattering encomiums of their friends, Mr. George and Dr. Woodforde, as also by the gratifying manner in which those remarks had been received by the meeting. He had much pleasure in the trammels of office, although sometimes inconvenient in the amount of time required; he could truly say that, between himself and his colleague, it was a work of mutual comfort and co-operation, and it would continue to be a labour of love with them both so long as the members supported them by a full and zealous attendance at their most interesting quarterly meetings. He would beg to move the next resolution as to the future appointment of Council. It would be recollected that, at the last annual meeting, a change was proposed with a view to destroy even the semblance of a continuous self-elected Council, and the plan was sketched out on the spur of the moment without sufficient deliberation as to detail. As often happened, such hasty legislation required revision; the resolution which he now read was simply to effect the more easy working of the plan of last year. Mr. Crang seconded the resolution, which, after some remarks from several as to whether the retiring members of the Council should be re-eligible for their own vacancies, was carried unanimously as follows:—

"That all the Members of this Branch Association be arranged, according to their localities, under two sections only, viz., Bath and Bristol, and that the members of Council, half of whom shall belong to each district, shall be elected only by the members of that district. That the Council shall consist of not more than twenty-nine members, viz., retiring President, the President, and President-Elect, and the Honorary Secretaries, *ex-officio*, and twenty-four other members, to be elected by ballot, one-third of whom shall retire annually. That the Council for 1851 shall determine among themselves the names of the eight members who are to retire in 1852 and 1853 respectively, so as to permit subsequently the retirement of one-third by rotation. That for the purpose of filling up the annual vacancies a printed list of the members of this Branch be transmitted, together with the notice of the annual meeting, to each member, who shall return the same to the Secretaries not less than ten days before such meeting, that the result of the ballot may be then declared by the scrutineers."

George Norman, Esq., moved, and Edward Humpage, Esq., seconded the seventh resolution,—

"That this meeting do approve of the memorial to the Right Hon. Sir George Grey, Bart., &c. &c., now read, as having been adopted and presented by the central Council of this Association."

Passed unanimously.

Dr. Wm. Davies in a few terse but appropriate remarks congratulated the Royal Colleges of Edinburgh upon the step they had now taken in regard to homœopathy. He was quite aware that the scandal of a professed homœopathist remaining as Physician to the Infirmary and Clinical Professor had been prevented by them, and that difficulties existed in doing more so long as the Professor of Pathology carefully avoided touching upon, ex-cathedrâ, his own peculiar tenets in regard to therapeutics. Still he thought it must be acknowledged that even this circumstance, although perhaps not so mischievous in its effects upon the student, did not lessen the anomalous position of the University; and he had much pleasure in moving the following resolution:—

"That this meeting has seen with much satisfaction the resolutions unanimously adopted by the Royal Colleges of Physicians and Surgeons of Edinburgh, regarding practitioners of homœopathy, and desires to offer its best thanks to them for their expressed determination to uphold the science of medicine by severing from their body those who act in a manner so unbecoming the character of either the physician or the surgeon; and that this resolution, signed by the President and Secretaries on behalf of this Association, be transmitted to the Presidents of the Colleges."

Dr. Tunstall briefly seconded the resolution, which was carried with much applause.

Thanks were voted to the Committee of the Medical Library for their kindness in accommodating the Society, and to the Chairman for his urbanity in conducting the business of the meeting. The members then adjourned to the Bath Hotel, at Clifton, where thirty sat down to enjoy the pleasures of social intercourse over a table well supplied by the Messrs. Hemsley.

YORKSHIRE BRANCH.

The Annual Meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association was held at the Medical School, Surrey Street, Sheffield, on Thursday, July 3rd. There were present—Dr. Branson of Sheffield, President; Mr. Allanson, Dr. Bartolomé, Sheffield; Mr. Boddington, Chesterfield; Dr. Elam, Mr. Favell, Mr. Finsley, Sheffield; Mr. Foster, Ecclesfield; Dr. Hall, Sheffield; Mr. S. Hey, Leeds; Mr. Husband, York; Mr. Harrison, Mr. H. Jackson, Mr. W. Jackson, Mr. E. Jackson, Sheffield; Mr. Kitching, York; Mr. Law, Sheffield; Mr. Pyper, Assistant-Surgeon, 11th Hussars; Mr. Parker, Mr. Porter, Mr. Reedal, Mr. Roper, Mr. Skinner, Mr. Smith, Sheffield; Dr. Simpson, and Mr. Williams, York.

The President then addressed the meeting as follows:—

Gentlemen,—Four years have elapsed since the members of the Yorkshire Branch of the Provincial Medical and Surgical Association assembled in Sheffield, and it is my pleasing duty, in the name of the medical practitioners of the neighbourhood, again to bid you welcome. Nineteen years ago the seed of this Association was just sown, and we have now a goodly tree

with branches stretching far and wide. It is unnecessary for me, therefore, to enlarge upon the value of the Association, when its merits are thus practically recognized. Custom has, however, prescribed to the occupant of this chair, the duty of opening the proceedings of the day with some introductory remarks, which, as our time is limited, I assure you shall be very brief. Since the last meeting of this branch of the Association we have witnessed the advent and departure of an appalling pestilence. An enumeration of the various plans of treatment adopted (their name is legion) only proves how powerless was our art as an antagonist to the deadly scourge, when the symptoms were once fully developed. Every variety of treatment which ingenuity could suggest was tried in vain. In London alone 15,000 souls perished; and it has been said that in Britain more lives were lost than have fallen in battle since the days of Marlborough. Though our remedies were thus powerless, have we gained no wisdom from the march of the mysterious enemy? Much, every way. We have learnt that sanitary improvements can alone oppose a barrier to future visitations of cholera, and that a comprehensive scheme of sanitary legislation must be carried through by the Government. In this town preventive and precautionary measures were actively employed with the happiest results; and it is creditable to the Board of Guardians that no parsimonious feeling prevented them from liberally remunerating their large medical staff, and creditable to the ratepayers, that the liberality of the guardians was cordially approved. The system adopted was the following:—Dispensaries were established in various parts of the town, at which only a single dose of medicine in each case could be obtained. The name of the applicant was immediately forwarded to the medical officer of the district, who, as soon as possible, visited the patient. The earliest symptoms of diarrhœa were thus promptly attended to, and the applications for relief were so numerous and general, as to render house to house visitation unnecessary. No cholera hospital was established, but from every house in which a case of cholera occurred the healthy were at once removed to a house of refuge, and those suffering from diarrhœa to a diarrhœa hospital; and no one was permitted to return to the infected house, until it had been thoroughly purified. By the adoption of this plan we have every reason for believing that the rate of mortality was greatly reduced, and that the expenditure of money, though large, was in the end true economy.

It is impossible to allude to sanitary legislation, without at the same time noticing the question of intra-mural interments. The rapid increase of the population;—the limited space assigned to the older churchyards, and consequently, the unavoidable disturbance of the soil before the remains of mortality have returned to their kindred dust;—the noxious emanations arising from these depositories of disease and the indisputable evidence of the injury to health, caused by the diffusion of pestilential gases through the neighbouring atmosphere, have all forced the question of intra-mural interments so urgently upon the public that few inhabitants of the larger towns are now found bold enough to defend the practice. The town church-yards have long ceased to be the quiet resting places of the dead; the disgusting scenes too frequently witnessed in them have thoroughly dissipated the illusion, and however much difference of opinion may exist in the minds of thinking men as to the best means of carrying out the alteration, the propriety of the change is rarely questioned, and there is every reason to hope that the day is not distant when this stain on our boasted civilization will be wiped away, and that a line will be drawn between the dead and the living, that the plague may be stayed. It is the duty, therefore, of every member of the profession to exert himself to the utmost to remove this national disgrace. It is to be hoped that the Society recently established in London for the investigation of epidemic diseases, under the somewhat inharmonious title of Epidemiological Society, will be the means of bringing to light and concentrating a mass of information of real use as a practical guide to the sanitary reformer.

Since the last meeting of the Branch, a very remarkable trial occurred, of grave import as affecting the medico-legal relations of insanity, if the law was correctly laid down by the presiding judge. I allude to the case of Nottige *versus* Ripley, in which the Lord Chief Baron emphatically stated, that all lunatics not dangerous to themselves or others, ought immediately to be liberated, and strongly urged on the commissioners of lunacy the duty of acting accordingly. It is painful to contemplate how much doubt and uncertainty must necessarily arise from a decision so authoritatively given, and so contrary to the received opinions in our profession. If the object of confinement in an asylum was merely the safe keeping of the lunatic, this dictum of the judge might be intelligible; but surely, in these enlightened days, when asylums have been changed from gloomy dungeons into houses of mercy, in which the primary object is the recovery of the patient, rather than the safe custody of the prisoner, such an opinion is monstrous in the extreme. In the name of suffering humanity let us protest against the doctrine, and claim for our afflicted fellow-creatures the right of being carefully and tenderly treated in the earliest stage of their distressing malady; the right of having the best chance afforded them of being again restored to society, with a sound mind, in a sound body. How many individuals are now useful members of society, who, in all human probability, would have ended their days as hopeless lunatics, had they been deprived of that restraint so necessary for their recovery, merely because they had not manifested a sufficient amount of suicidal or homicidal madness legally to justify their seclusion.

I cannot congratulate the members of the Branch upon any advance towards the suppression of quackery. The columns of the daily prints teem, not merely with the most unblushing, and too often disgusting recommendations of nostrums and specifics, sanctioned most inconsistently by the Government authorities, which profess to be actuated by a sincere desire to promote sanitary improvement, but, alas! we have also abundant

evidence that even intellectual minds are not proof against the delusions of quackery, when presented under the specious garb of homœopathy, hydropathy, or mesmerism. That some of the professors of the first of these pseudo-sciences are honest in their belief, it would be uncharitable to doubt; but words cannot be found sufficiently strong to stigmatise those renegades from our ranks, who, having bartered for filthy lucre the faith in which they were educated, secretly rely in their hour of need on the very remedies they have publicly renounced. The Edinburgh College of Physicians have most justly resolved,—"That no Fellow of this College, nor any other Physician"—(I would add any other practitioner of legitimate medicine)—"can, by any possibility, without derogating from his own honor, and from the honor of the profession, meet practitioners of homœopathy in consultation, or co-operate with them in the common duties of professional life."

The warfare is still carried on between the Insurance Companies and the profession; and from the goodly list of companies which can now be pointed out as trophies of victory, it is hoped that an amicable adjustment in terms satisfactory to both parties, may ere long be accomplished. The companies, not without reason, contend that the insurer is bound to furnish evidence as to the eligibility of his life for insurance, and, consequently, that the payment for that evidence rests with the insurer. The difficulty might easily be arranged by the company in the first instance requiring a fee to be deposited by the applicant for insurance, to be paid through the company to the private medical referee. This, it is humbly submitted, would meet the justice of the case, and put an end to the painful disputes which now take place between the Insurance Companies and the profession.

The claims of the army and navy surgeons to a share in the honours distributed to the officers of their respective services, have at length been admitted. We, who can appreciate the value, I had almost said difficulty, of preserving an unruffled mind, even in the operating theatre of an hospital, with all the advantages that previous consultation, calm thought, and the most perfect preparation can afford, know well how trying must be the situation of the surgeon when compelled to perform his anxious and responsible duties amidst the excitement and danger of battle, the roar of cannon, and the groans of the dying. Surely he who can thus calmly endeavour to alleviate the sufferings of his fellow-creatures, and mitigate the horrors of war, is as much entitled to the graceful honours of an approving country as the most distinguished general on the field.

The steady and united efforts of the naval assistant-surgeons, to place themselves in a position befitting their age, rank, and education, have gained that consideration and attention from Parliament which the officials of the Admiralty so perseveringly denied them. As civilians, we have ever warmly sympathized with our naval brethren under their grievances, and cordially congratulate them on the prospect of better times.

A new edition of the London Pharmacopœia has lately been issued, and another opportunity lost of producing, in concert with the Colleges of Scotland and Ireland, a truly national and consistent work.

An Act to prevent the indiscriminate sale of arsenic has been passed in the present Session of Parliament. In the success of this Bill the Provincial Association has taken the warmest interest. The fearful facility afforded to the perpetration of crime (particularly in some agricultural districts), by the ready access to this deadly poison, and the difficulty of detecting the symptoms during life, when the mineral is administered in small, repeated, and slowly poisonous doses, have at length induced the Government to legislate on the subject. Whether the Bill is sufficiently stringent, and whether other virulent poisons might not with advantage have been included in its clauses, is very questionable. This Association will doubtless anxiously watch the effect of the measure, and, if need be, press upon the Government the propriety of more vigorous legislation.

The great injustice of the unequal Income-tax has been borne too tamely by the profession; and as Parliament has only sanctioned its renewal for one year, to afford an opportunity for further investigation, the time for action has arrived, and I trust the general meeting of the Association, at Brighton, will not be allowed to pass over without some decided steps having been taken to urge upon Parliament, in every possible way, the hardship and injustice of the tax as it affects professional incomes. Unless the members of our profession now unite to petition against this inquisitorial and obnoxious impost, both Parliament and the Government will have a right to construe silence into apathy, and re-impose the tax in its present unjust form.

I cannot resist the opportunity now afforded me of urging upon your consideration the propriety, or rather duty, of supporting the Benevolent Fund in connexion with this Association, I must confess that for a long time my prejudices were strongly in favour of local medical charitable associations, believing that a Society like our excellent West Riding Medical Charity was better adapted to examine into the peculiar claims of individual cases of distress than a charity on a more extended scale. It is, however, impossible to read the painful reports of the Benevolent Fund without feeling convinced that ample room exists for the fullest exertions of our charity, without in the smallest degree interfering with the efforts of local benevolence; and that cases of unavoidable and sudden distress are too constantly occurring quite out of the reach of a charity which distributes its funds annually, and requires five years' membership to entitle the sufferer to relief. To cases of sudden distress the Benevolent Fund is especially applicable; "*Bis dat qui cito dat*" is its motto; and many are the individuals who have reason to bless the Association for its timely and unostentatious succour.

The question of Medical Reform has been so frequently canvassed, that I may well be excused from entering upon it on the present occasion, and particularly as there now seems a prospect that the various Colleges will make alterations in their respective Charters

of a sufficiently liberal character to satisfy all reasonable members of our profession; it is, therefore, a matter far congratulation, that no hasty legislation has been forced upon us. The present time seems peculiarly fitted for a satisfactory settlement of the question. The stormy waves of Medical Reform have considerably subsided. The appointment, at Worcester, of a committee of our Association to report on medical ethics, and the establishment of medico-ethical societies in various parts of the country, clearly indicate a growing feeling amongst us that something more is required for the peace and harmony of our profession than legislative enactments. To societies like our own we must look for the maintenance of professional honour. Let the banner of the Provincial Association be inscribed with the emblems of truth, candour, and charity, and he who enlists in its ranks, and fights under its colours, must remember that any dereliction of duty, any deviation from the strict line of professional conduct, morally or medically, renders him a traitor to the cause he has espoused, and can only entitle him, at the hands of his professional brethren, to the well-deserved punishment of a deserter.

The SECRETARY then read the

Report of Council.

In presenting to this meeting their usual Report, your Council would congratulate the Branch on again revisiting a locality, where the science of medicine is cultivated with so much energy and success. The annual meeting for last year ought, as most present here are no doubt aware, to have been held here, but your Council having considered that the anniversary meeting of the Parent Association was appointed to be held within the county, determined, as a mark of filial respect, and for the convenience of the members to exercise, it may be a somewhat unconstitutional power, and defer the meeting until this year. A vote of indemnity from this meeting is scarcely required, as not even the gentlest murmur of discontent has reached your Council.

The Central Council at Worcester desires the opinion of this and the other branches on the present state of the Medical Reform question. Although the Institute has adopted the last desperate effort of applying to Parliament to sanction the scheme of a college of general practitioners, your Council has had much pleasure in witnessing the defeat of the obnoxious proposal by the politic conduct of the Colleges of Physicians and Surgeons. Midwifery has been allowed to rank as a department of medical science, and the practice of the obstetric art is no longer ignored by the examiners of the English surgeon, who, skilled though he may be in conservation or excision, may be often baffled by the Protean and dangerous complications which the parturient process too frequently presents. The fellowship is not to be confined to a chosen few, and the provincial surgeon may now take his place in the council of a body, of which his class forms so large a majority. The Council of the Association has already drawn the attention of the Secretary of State for the Home Department to the often-asserted opinion of the Association, that no plan of Medical Reform will meet the exigencies of the case, which does not contemplate a a board of examiners chosen conjointly by the medical and surgical colleges, whose examination shall test the fitness of every one to practise the profession, and whose certificate shall be the sole licence to practise in any department of medicine.

Whatever defect may exist in details, your Council is of opinion that a modification of existing institutions is far preferable to the establishment of another medical corporation, by which an already too much divided profession would be still further disunited. Medicine is a science one and indivisible. The day has long since passed away when the surgeon presumed not to amend the health of his patient by the most trifling internal remedy, and the physician's opinion is now often sought in a surgical case, for slender are the partitions of medicine and surgery, and difficult would it be sometimes to decide on which side of the barrier the case should range. Hence the general practitioner claims connexion with the representative heads of medicine and surgery, and wishes not to exchange the fostering influence of colleges which can boast a Baillie and a Hunter, and many others of lasting fame, for a new institution which would present names known only in the immediate locality of those who bear them.

Whatever opinion the members present may determine to express, your Council, though gratified by a probable arrangement of this disputed question, cannot but express their sense of the gratitude due from the profession to an institution which, under a new order of things, will cease to have that controlling influence over medical education which it has so judiciously and successfully exercised. The Apothecaries' Company, as a licensing body, must soon cease to exist, and many a happy and consoling thought must gild the last moments of its existence. No medical corporation has done so much, and so judiciously, to elevate the position of the British practitioner of medicine as the Court of Examiners of the Apothecaries' Company. Ever ready to anticipate the requirements of the times, the Hall has gradually and judiciously raised the standard of medical education, until the general practitioner has been enabled to occupy a far higher position in the profession and in society than was held by his predecessors before the year 1815. All praise, then, and gratitude, let us express and feel towards those well-judging and retiring men who have done more for the diffusion of medical knowledge than many whose names are blazoned on the muster-roll of fame. But all should feel that, whatever reform may be effected, to individual exertion and integrity must we look for the well-doing of the general body. If each, keeping always in view the responsibility and dignity of the *ars medendi*, shall always strive to maintain the *mens sibi conscia recti*, and a determination to cultivate to the utmost those talents which a kind Creator has intrusted to his charge, the empiric may carry on his impudent deceptions for a time, but in the end *magna est veritas et prævalebit*, and by the character and attainments of each, the whole community will be raised higher and higher in the estimation and respect of men.

The Secretary, who has held his office for above ten

years, expressed to your Council some time ago his intention of resigning his office at the present meeting, and it remains with you to appoint his successor.

The following resolutions were then unanimously adopted:—

1. Moved by Mr. H. Jackson, seconded by Dr. Bartolomè,—"That the Report of the Council just read be received and adopted."

2.—Moved by Mr. Husband, seconded by Mr. W. Jackson,—"That in the opinion of this branch, a modification of existing Medical Corporations is decidedly preferable to the establishment of a College of General Practitioners, which would tend to disunite the profession, and be injurious to the best interests of the general practitioner."

3. Moved by Mr. Kitching, seconded by Mr. Foster, —"That the following be appointed the Branch Council for 1851:—Mr. James Allen, H. S. Belcombe, M.D., Mr. B. Dodsworth, Mr. R. Hey, T. Simpson, M.D., Mr. C. Williams, Mr. W. D. Husband, *York;* C. Chadwick, M.D., Mr. G. F. Garlick, Mr. W. Hey, Mr. T. P. Teale, Mr. T. Nunneley, Mr. S. Smith, *Leeds;* T. Branson, M.D., Mr. H. Jackson, M. De Bartolomé, M.D., Mr. W. Jackson, Mr. G. Turton, Mr. G. Reedal, *Sheffield;* T. Sandwith, M.D., *Beverley;* Mr. H. G. Whytehead, *Craike;* Mr. J. Ness, *Helmsley.*

4. Moved by Mr. Williams, seconded by Mr. H. Jackson,—"That Mr. W. Matterson be elected Secretary and Treasurer for the ensuing year."

5.—Moved by Dr. Bartolomé, seconded by Mr. W. Jackson,—"That the thanks of this meeting are due, and are hereby given to Mr. Husband, for his services to the Branch, as its Secretary, for the last ten years."

6.—Moved by Dr. Simpson, seconded by Mr. Williams,—"That the meeting of the Branch for 1852, be held at Leeds, and that Dr. Chadwick be chosen President-Elect."

7.—Moved by Mr. Williams, seconded by Mr. S. Hey,—"That the thanks of the meeting be given to the President for his able conduct in the chair."

The following communications were then presented to the meeting:—

1. "Case of Cancroïde Cylindracée (Alibert) following a Burn." By Mr. Law. Illustrated by a beautiful representation of the disease, by the President, and the presence of the boy, the subject of the disease.

2. "Singular Case of Calculus." By Mr. H. Jackson.

3. "Case of Scirrhus of Cardiac Orifice of Stomach, in which no food was taken by the mouth for six weeks, and the patient sustained by Nutrient Injections."

4. "Case of Cancerous Ulceration of the Stomach." By Dr. Simpson, and Mr. Williams.

5. "Case of Ossification of Muscular Structure of the Heart." By Dr. Bartolomé.

6. "Case of singular Perforation of Stomach." By Mr. Law.

The members then adjourned to dinner at the Angel Inn, where they were joined by the Rev. Canon Blackburn, and other visitors, and enjoyed a pleasant evening under the kind Presidency of Dr. Branson.

EPIDEMIOLOGICAL SOCIETY.

July 7, 1851.

At the ordinary meeting of this Society, held this day, at the house of the Royal Medical and Chirurgical Society, 53, Berners Street, Dr. Addison in the chair, the following donations to the funds were announced: A donation of ten guineas from the Guardian Life Assurance Company, a donation of ten guineas from the Pelican Life Assurance Company, a donation of ten guineas from the Eagle Life Insurance Company, a subscription of one guinea annually from the Anchor Life Assurance Company.

Mr. Hunt then read a paper—

On the Uses and Limits of Statistical Science, as applied to the Study of Epidemics.

The object of the author was to shew in what departments the statistical method was likely to prove most satisfactory, and to elucidate the principles of its application. He commenced by regretting the injury which the cause of medical science has suffered, from a loose and limited method of statistical inquiry into the phenomena of epidemics; deprecated the publication of extraordinary cases, and attaching a statistical value to them, while the ordinary cases were overlooked; and commended the proper use of statistics as the natural correction of the false conclusions thus arrived at. Mr. Hunt regarded therapeutics as a branch of medical science in which statistical inquiries would be unavailing, both on account of the variety of subjects, and the diversity of circumstances which must be taken into the account, and also from the impossibility of discovering, in each individual case, how the patient would have fared if his disease had not come under treatment at all. For these reasons it was urged that our knowledge of the art of healing must be derived, rather from analogy and observation, than from rigid induction. The author concluded by instancing the protective power of vaccination as a very fair question for statistical examination, and expressed a hope, that the profession would extensively respond to the questions issued by the Society on that important subject.

Drs. Addison, Theophilus Thompson, and Seaton, and Mr. Walsh, took part in the discussion on Mr. Hunt's paper.

It was announced from the chair, that a paper "On the Nature of Epidemics," by Mr. Grove, of Wandsworth, would be read at the ordinary meeting, to be held on Monday, August the 4th.

Foreign Department.

FRANCE.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

The following are the most interesting subjects which have recently come before the notice of the Society:—

M. Danyau read the account of *a fibrous tumour of the anterior lip of the uterus,* which offered an impedi-

ment to parturition. It was found on examination to occupy the whole vagina, and extended backwards into the concavity of the sacrum. M. Danyau decided on enucleation, in preference to the Cæsarian operation; and on dividing the uterine tissue was able to remove the impediment, and a dead child was speedily born.

M. Bouvier narrated a "Case of Internal Hernia," caused by strangulation of the small intestine in a diverticulum from the ileum; and the discussion turned chiefly on the propriety of gastrotomy when the seat of the strangulation is made evident by a tumour.

M. Moreau presented a memoir "On the *Premonitory Signs of Insanity*." Among the most important of these he places repeated seizures resembling cerebral congestion, sensations analogous to the aura of epileptics, nervous pains like neuralgia, vertigo, syncope, &c.

The *Compression of the Aorta in Internal Hæmorrhage* was the subject of a memoir by M. Chailly-Honore. The author has collected notes of eighteen cases in which this proceeding was adopted; in seventeen of these the flooding ceased instantaneously. One woman died, although the bleeding was completely controlled, she being anæmic previously to her confinement.

A contribution to the pathology of *Congenital Syphilis*, has been made by M. Depaul, consisting in the discovery of a particular intra-uterine lesion of the lungs. His conclusions are to the following effect:— 1. Intra-uterine syphilis is more common than is generally allowed. 2. It may be transmitted by mother or father, or both. 3. In addition to the more generally known appearances in the infant which are attributed to syphilitic contamination, another must be admitted, which consists in disseminated purulent deposits in the lungs. 4. When an infant has been born with the lesion, the parents should be submitted to an anti-syphilitic treatment.

[It may be stated that Mr. Acton, in his recent treatise distinctly denies that infantile syphilis ever manifests itself at birth; he, however, alludes more particularly to the external appearances, as papulous eruptions, condylomata, &c.]

The *Cæsarean Operation* has been successfully performed by M. Bouchacourt, &c., but the case is not reported at length.

ACADEMIE DES SCIENCES.

Another *New Anæsthetic* has been exhibited, with the name of "Bromhydric ether." It is said to have neither taste or smell in the least disagreeable.

M. Boucher communicated the results of his researches on the *Detection of the Mineral Poisons* in the nervous system. At present he has limited his analysis to arsenic, lead, copper, and mercury. Each of these metals was readily detected in the brain of dogs previously poisoned.

Case of Serious Hæmorrhage following Excision of the Tonsil.

The following instructive case forms the subject of a memoir by M. Chaissaignac, (*Archives Générales*, Mai.)

The patient, a female, aged 21, was the subject of enlarged tonsils, one of which had been removed eight days before by M. Sandouville. The operation had been quite successful in its immediate results. The author was summoned in consequence of an incontrollable spitting of blood. On looking into the throat for the purpose of discovering the exact seat of the hæmorrhage, M. Chaissaignac found that it proceeded from the bottom of a concavity left by the excised tonsil.

The patient had been for some time constantly spitting blood, and had also vomited a large quantity. The pulse was small, the extremities cold, and altogether she was in imminent danger. Many means had been adopted without success, such as ice externally, and styptics of various kinds internally.

The first proceeding adopted by the author was to make pressure on the bleeding surface with lint dipped in lemon juice. This controlled the bleeding for a time, but after he had left it returned with equal intensity. He now intended to apply the actual cautery, but before resorting to this it occurred to him to try keeping up pressure on the tonsil with lumps of ice. This was done with the aid of forceps, and was completely and permanently successful.

Diaphragmatic Hernia of the Stomach, Spleen, and Colon.

This curious case is published in the *Revue Medico-Chirurgicale*, Juin, 1851. The patient, aged 59, was admitted into the Hotel Dieu of Nantes in June, 1850, complaining of pain in the epigastric region, constant vomiting, cough, and purulent expectoration. He died at the end of three weeks. After death the stomach, omentum, spleen, and a portion of the colon, were found in the thorax, having passed through an opening to the left of the pillars of the diaphragm; the opening had smooth edges, and did not exhibit any appearance of laceration. There was no trace of inflammation, either in vascularity or adhesion, so that the inference was that the hernia was congenital, and that the vomiting towards the close of life was in some way connected with the state of the lungs, which were full of phthisical excavations.

On the Proportions of the Human Skeleton.

M. Carus, of Dresden, has been endeavouring to discover the standard measure upon which the human frame is constructed, and considers that he has found it in the vertebral column. He states that the spine in a new-born child is just one-third of what it becomes in the adult; and he, therefore, takes the third part of the vertebral column as the above-mentioned standard. The head, for instance, its length and breadth taken together (without the lower jaw, which is a sort of extremity of head), is just the size of the standard

measure; on the trunk each clavicle, with the acromion, the sternum, and each scapula, may be measured upon the same suit. Such is likewise the case with the pelvis. The normal length of the arm is three measures, the hand one, the foot one, the tibia two, the femur two and a half, &c. The whole length of the body comprises in the normal state nine and a half of the standard measure. M. Carus has had a small figure constructed upon which these varous proportions are accurately marked.

Excision of the Astragalus, Successfully Performed, for Fracture and Dislocation of that bone.

Although the history of fracture with dislocation of the astragalus, requiring the extraction of the bone, has been succinctly written, there are comparatively but few cases on record, so that the following instance by M. Thore (*Archiv. Générales*, Mai) is not without value:—

A young man working in a stone quarry had his right foot crushed by a fall of stones and earth. When first visited the foot and leg were enormously swollen, so that it was difficult to ascertain the nature of the injury. The foot was, therefore, enveloped in poultices. Five days subsequently a gangrenous odour was perceptible, and bullæ appeared filled with fœtid sanies. At the external aspect of the foot the skin was sloughing, and a portion of the astragalus projected, and was moveable in all directions.

Two days after the author decided to extract the bone. After enlarging the wound the bone was seized in strong forceps, and the ligamentous structures being divided it was readily extracted, leaving a large and deep excavation.

The report five days after the operation is, that the appearance of the limb is much improved, the gangrene diminishing, and cicatrization commencing in certain portions of the wound. Several splinters were extracted, and phlegmonous erysipelas ensued, requiring several incisions for the purpose of evacuating pus; but on the subsidence of this the patient made rapid progress.

An examination of the limb was made at the expiration of the year, when the following were the appearances:—Above and immediately behind the external malleolus there was a deep semicircular cicatrix. There was no trace of callus either on the tibia or fibula. The external malleolus is more prominent than the other. The concavity of the sole of the foot was little changed. The foot, which was for a long time moveable in every direction, was at this time quite anchylosed. The patient could walk and even dance without pain and with facility.

General Retrospect.

PHYSIOLOGY.

Vital Contractions in the Umbilical Arteries and Veins.—By Professor Simpson.

The reality of these long doubted phenomena has been effectually pointed out by Dr. Simpson, who has satisfied his class of the following facts:—

1st. After the child is born, the cord, (whether tied or not,) is generally seen to become contracted at different points, in consequence of the local contraction at those points of the vessels included within it; in fact, its vessels are thrown, by the irritation of the external atmosphere, and in consequence of their partially empty condition, into tubes consisting of a series of dilatations and contractions, like the peristaltic contractions of the intestine, but with this difference, that the contractions of the vessels are permanent.

2nd. By pinching a portion of the cord, immediately after the birth of the child, between the nails of the thumb and finger, contractions of the vessels of the cord will be seen to occur at the point irritated. And if this mechanical irritation is confined to individual vessels, as to one of the arteries or to the vein, the effect is equally marked.

3rd. If the sheath of the cord be slit up by a pair of scissors or a knife, with any of its vessels or arteries exposed, the same experiment may be repeated upon the exposed individual vessels with similar effect, viz., that the mechanical pinching of them will be followed in the course of a short time by a gradual but very marked contraction in the irritated part.

4th. Similar local contractions of these vessels occur, under the local application to them of irritating chemical substances, or of electricity.

5th. These contractions do not instantly follow the application of the stimulant, but a short time intervenes before the effect is seen, and the contraction is permanent.

6th. When the experiment is made upon the human umbilical cord, or upon that of the lower animals, when the circulation is still going on in the vessels of the cord, the irritated vessel will sometimes almost entirely close its tube under such local irritation.

7th. These simple experiments, illustrative of the contractility and irritability of the coats of the veins and arteries, are the more remarkable as seen in the umbilical veins and arteries, in consequence of anatomists not being able to detect any nerves in the umbilical cord, although probably elementary nervous tissue may exist in some form in it; for if it did not exist, then we would have irritability in these vessels existing without nervous influence. And Dr. Simpson proposed the investigation of the existence of nerve in any form in the umbilical cord and its vessels, as an interesting microscopical study, in reference to the physiological question of the dependence or independence of the contractility of vessels on the presence of nerves.—*Edinburgh Monthly Journal*, May, 1851.

SURGERY.

Popliteal Aneurism: Treatment by Compression.—By Mr. Paget.

In this case the treatment, by means of Dr. Carte's apparatus, was commenced on January 31st. Two instruments were applied and alternately tightened and relaxed. These caused great pain; and, after the

fourth week, were changed for the Italian tourniquet. From this time till the 16th of February, the size of the aneurism decreased; but, after ten days, no further progress was made. On the 21st of March the diminution recommenced; and by the 18th of April it was reduced to the size of a hazel nut, but still pulsated freely. After eleven weeks' confinement, the patient's patience became exhausted, and he wished to move about; but modified pressure was kept up for six weeks longer, when pulsation one morning suddenly ceased, and the aneurism was cured.

In commenting upon this case, Mr. Paget remarks, that the disease was, probably, an example of aneurismal dilatation, or, as Mr. Luke has named it, tubular aneurism; an aneurism of the cylindriform or fusiform variety described by Cruveilhier,—that is, a dilatation affecting, almost uniformly, the whole circumference of the artery in a certain portion of its length. Such dilatations are very rare in the popliteal artery; yet that such an one existed here is made very probable by many things observed in the case, and especially by the great diminution of size of the aneurism while under treatment.

The cure of popliteal and similar aneurisms, whether treated by pressure or ligature, is (Mr. Paget remarks) usually accomplished much more by the filling of the sac with blood-clot, than by the contraction of the sac. Hence, usually, after the pulsation has ceased, the swelling, with comparatively little diminution of size, remains firm and nearly solid, till slowly its size is diminished by the absorption and shrinking of its contents. When, however, as in the case here related, a popliteal aneurism consists in a dilatation of the whole circumference of the artery, we may believe that there is the same indisposition to the formation of clot as in the similar dilatations of the arch of the aorta, and of other great arteries in which no part of the dilatation is far remote from the main stream of blood. In all these cases it is matter of common and just observation, that fibrinous deposits are scanty and rare; and, therefore, in the similar dilatations of the smaller arteries, we might expect that the effect of any continued obstruction of the trunk would be the gradual contraction of the dilated portion, rather than its filling up with clot.

Other considerations, Mr. Paget thinks, strengthen this opinion of the nature of the case here related; especially, first, that as the enlargement of the artery after the injury was very slow, there was probably no rupture or serious damage of its coats, but that such a change as might lead to their slow and extensive impairment of structure; and, secondly, that the sensation derived from the touch of the dilatation was always that of a sac tensely filled with fluid, and containing no clots, such as are almost constantly found in saccular aneurisms, *i.e.*, partial or lateral dilatations of the arterial walls.

Commenting on the results of the treatment of this case, by pressure on the trunk of the artery above the aneurism, Mr. Paget thinks that, considering that the patient was instructed in surgery, and well understood the plan on which the treatment was to be conducted, that he had himself chosen this plan of treatment, and submitted to it without interruption, and that it was attended with no local injury or other inconvenience; few cases could have been better suited to the plan, yet so long a period elapsed prior to the cure, that he would not advise it in preference to ligature. He does not, however, discountenance compression, being disposed to attribute its tediousness, in the present case, to the peculiarity of the tumour above alluded to.—*Medical Gazette*, April 15, 1851.

Complications of Hernia.—By Mr. Robinson.

The following are the deductions from a paper on the above subject:—

1. Symptoms of strangulation may continue after a hernia has been reduced *en masse*. This may be owing to one of two causes; either to the return of the intestine to the upper part of the inguinal canal, and not into the abdomen, constriction, therefore, continuing at the internal ring, or to the return of the sac, with the hernia still constricted in it.

2. The intestine may be universally adherent to the sac.

3. The direction of the vessels cannot be relied upon as a distinguishing mark between the intestine and the sac.

4. Foreign bodies *may* pass through an irreducible hernia without injurious effects.

5. The bowels may redescend after reduction, again become strangulated, and again require operation.

6. Strangulation may occur in a person the subject of double hernia, and it may be doubtful which is strangulated. In such a case the oldest and most tense of the tumours should be first subjected to the knife.

7. Enlarged inguinal glands greatly complicate the diagnosis of hernia.

8. Strangulated inguinal hernia may prove fatal by rapid collapse.—*London Journal of Medicine*, May, 1851.

MIDWIFERY.

Causes of Hæmorrhage after Parturition.—By Dr. McClintock.

In an essay on post partum hæmorrhage, the author enumerates the following as the principal causes:—

1. The presence of a portion of the placenta in the uterus.

2. The retention of a coagulum in the uterus.

3. Simple relaxation of the uterine fibres.

4. Disturbance of the general circulation.

5. Fœcal accumulation. This is mentioned as a cause by Moreau.

6. Functional disorder of the liver. This is noticed as a cause of hæmorrhage by Dr. Ayres, but is not admitted as such by the author.

7. Ulceration of the os and cervix uteri.

8. Polypus or other morbid growth attached to the uterus.—*Dublin Quarterly Journal*, May, 1851.

Correspondence.

ISSUE OF DAY TICKETS BETWEEN LONDON AND BRIGHTON AT THE ANNIVERSARY MEETING OF THE ASSOCIATION.

To Sir Charles Hastings, M.D.

My dear Sir,—I am desirous we should have a large meeting at Brighton. I have seen the Secretary of the Railway, and he will obtain the sanction of the Directors to issue day tickets from London to Brighton and back at reduced rates, and to be available for three or more days to all, upon the production of a card or ticket shewing that they are members of the Provincial Medical and Surgical Association. Do you suppose that such a plan, if made known, would not be an inducement to many to attend the meeting. The Brighton gentlemen are doing all they can to induce the members to attend; they have secured the Palace for the Association, which also should be made known; that, coupled with cheap and expeditious communication between London and Brighton, might induce many to attend, if publicity be given to it. Please let me know your opinion, and I will take steps to secure the conveyance between London and Brighton to the members of the Association.

I hope to be there myself, and read a short case.

I am, my dear Sir,

Yours most truly,

GEORGE BOTTOMLEY.

Croydon, July 16, 1851.

Medical Intelligence.

THE COLLEGE FELLOWSHIP.

The Council have just announced that the next professional examination for this distinction will take place on Monday and Wednesday, the 4th and 6th of August.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 4th instant:—Thomas Abbey Bottomley, Huddersfield; Samuel Brown, Royal Navy; Henry Cole, Lewisham; William Henry Folker, Oxford; William Henry Harris, Barnstaple, Devon; Thomas Hales, Fort Green, Staffordshire; Francis Nuttall, Bury, Lancashire; John Richard Price, Holyhead, North Wales; Henry Bowles Sayers, Bandon, Cork; Buxton Shillitoe, Hertford; Robert Williams, Hirnaul, Montgomeryshire; Joseph F. Windus, Madras.

The following gentlemen were admitted on the 7th instant:—George Bull, Lewes, Sussex; William Huskisson Carter, Chichester, Sussex; Edward Parks Gamble, Cork; George Smith Delavil Harris, Blackhall, Sevenoaks, Kent; Leonard Henry Joseph Hayne, Royal Navy; Wm. Hurst, Valparaiso, South America; Charles Francis Lewis, Pimlico; Frederick John Money, Offham, Kent; Thomas Peete, Margate, Kent; Stephen Chapman Townsend Coleridge, Devon.

The following gentlemen were admitted members on Friday, the 11th inst.:—Capel Bringloe, Beccles, Suffolk; John Chapman, Leith, Mid Lothian; Francis Day, Uckfield, Sussex; Patrick Dillon, Ennis, County Clare; William Augustus Dobbyn, Dublin; Joseph Frederick Elsom, Limehouse; Samuel Martyn, Brook Street, Grosvenor Square; James Merryweather, Brook Street, Grosvenor Square; George Cochrane Millar, Clifton Street, Finsbury Square; Annesley Charles Castroit De Renzy, Hon. East India Company's Service, Bengal; John Frederick Vivian, Alladullha, near Sydney, Australia; Henry John Wilkin, Connaught Terrace, Hyde Park.

The following were also admitted on Monday, the 14th inst.:—John Baines, Falcon Square; Charles Breeze, Belfast: Henry Thomas Lucas Byne, Hammersmith; Robert Thomas Gagen, Crown Row, Mile End; James Stacey Hichens, Redruth, Cornwall; Samuel Wall Jones, Ludlow, Salop; Charles O'Regan, New Orleans; David William Pughe, Carnarvon; John James Ritchie, Tean, Staffordshire; Henry Thompson Shaw, Ballynahinch, County Down; Frederick Moore Smith, Much Hadham, Herts.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, July 10th:—Henry Greenway, Plymouth; Frederick Wm. Headland, Guildford Street, Russell Square; John Mackintosh, Inverness; Thomas Henry Taylor, Henbury, near Bristol.

BOOKS RECEIVED FOR REVIEW.

Practical Treatise on the Diseases of the Heart and Lungs. By W. H. Walshe, M.D. London: Taylor and Walton, pp. 580.

Digitaline—Rapports de M. Rayer. Soubeinan et Bouillaud. Paris. 1851.

The First Step in Chemistry. By Robert Galloway, F.C.I., &c. London: J. Churchill. 1851. pp. 91.

The Three Pharmacopœias, with Appendix. By Peter Squire, M.R.I., &c. London: J. Churchill. 1851. pp. 174.

On the Reciprocal Agencies of Mind and Matter, and on Insanity. By J. C. Badeley, M.D., Cantab., &c., &c.; being the Lumleian Lectures for 1851. London: J. Churchill. pp. 60

Braithwaite's Retrospect of Medicine. January to June, 1851.

Ranking's Half-Yearly Abstract. January to June, 1851.

Journal of Psychological Medicine. July, 1851.

London Journal of Medicine. July, 1851.

Monthly Journal of Medicine. July, 1851.

Quarterly Summary of the Transactions of the College of Physicians of Philadelphia, from November, 1850, to January, 1851. Philadelphia. 1851. pp. 55.

The Medical Examiner. May and June, 1851. Philadelphia.

The Charlestown Medical Journal. March and May, 1851.

The Establishment of a Dispensary for the Poor of Scarborough, suggested in a Letter to Peter Murray, Esq., M.D., President of the Archæological Society, etc. By Robert Cook, B.A., M.R.C.S.E., &c. Scarborough: S. W. Theakston, St. Nicholas Street.

TO CORRESPONDENTS.

Communications have been received from Mr. Ikin, Mr. Thursfield, Dr. Merei, Mr. Rice, Mr. Foster, Mr. Paterson, Mr. Gorham, Dr. Nelson, and Mr. Humphry.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

LECTURE

ON THE

DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By Dr. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE IV.

Diseases of the Heart; Abdominal Symptoms; Vomiting; some qualities of Diarrhœa.

I will conclude the examination of the chest with some remarks concerning the diseases of the heart. Chronic and organic affections of this central organ are rare in children. The fœtal communications very seldom persist above a few days after birth. Cyanotic colouration of the skin, in a slight degree, as I have had occasion to ascertain in children, arises sometimes from various disorders, in particular of the portal system. The *bellows-sound*, sometimes the purring, must be always present in the case of unclosed fœtal communication of the auricles; but it must be remarked, that bellows-sound and palpitation are also the essential symptoms of a certain degree of chlorotic anæmia, and in this case we perceive a similar sound even over the carotids. Some authors say, that, acute affections of the heart and pericardium are very obvious in children; I did not frequently meet with either pericarditis or endocarditis in infants and young children. At the commencement of both of these affections, our hand laid beneath the areola mammæ, will perceive very violent pulsations, even visible by correspondent movements at that part of the chest. If percussion gives a more or less extensively dull sound over the heart, and, by auscultating, we hear less clearly the natural sounds of the circulatory movements, we must suspect transudation in the pericardium. In the second stage of pericarditis, if only a small quantity of lymph is exuded, we hear, not always, a distinct rubbing sound, or *friction*; but then, after some more lymph has been transuded, the rubbing sound becomes more hard and more audible. Rubbing, then, is the character of the exocardial murmur. The further progress of transudation is noted by increasing dulness, if we purcuss. If, on the contrary, these phenomena are absent, and we hear an abnormal murmur, like strong blowing, *bruit de souffiet*, in particular joined with the first or systolic sound, this denotes endocarditis. The best English authors call this the endocardial murmur. If these affections are acute, we observe almost always a dry cough, dyspnœa, with occasional long and deep inspiration, anxiety in the countenance, and invariably elevated dorsal position, and expression of pain; which symptoms are absent in chlorosis.

Dislocations of the heart in consequence of large pleuritic exudations in the left side, easily give rise to a mistake in diagnosis. Some authors say that this case is rare in young children. In fact, I cannot say I have frequently met with them, but still, nearly as frequently as with idiopathic inflammations of the heart. I have even seen some children, about two years old, survive this serious derangement, and more of them at a more advanced period of childhood. In one of these cases which I examined four months after the affection took place, the basis of the heart was protruding one inch on the right side of the sternum: percussion gave a moderate dull sound at the lower-third of the left side of the chest, laterally and anteriorly, and the vesicular murmur was not yet clear enough; no doubt, in this case, besides the transudation, which was already absorbed, extensive adhesions took place between the pleura of the lung, that of the chest, and that of the diaphragm; consequently, the displacement of the heart became permanent. Less important degrees of this mechanical disorder of the heart I met with more frequently, which we are always enabled to discover by touch, auscultation, and percussion. There is constantly a certain degree of dyspnœa and much propensity to palpitations, which prevent the affected individuals from walking quickly.

You can find very valuable information about carditis and pericarditis in Dr. West's (of London) lectures. Only I must observe, that, according to my experience, acute inflammation—exocardial as well as endocardial—in infants and very young children, causes in general, very soon, convulsions, and death before severe material changes could take place.

The *symptoms of the abdomen* are worthy our fullest attention. We look at first at the *volume* of this part. A large abdomen combined with a large skull, and thin flabby extremities, is a symptom of scrofula or rachitis. The examination of this part must be performed with delicacy and cleverness, in order to prevent crying, during which the abdominal muscles are in a state of tension, which prevents our detecting material disorders; and as then, a crying child is also peevish, we cannot easily distinguish if pressure causes real pain. It is frequently necessary, to steal from behind towards the child placed in the arms of its nurse, and then put our flat hand transversely on the upper part of the belly. Thus, we commence to exert gradual pressure, and if the child cries violently we make use of the act of inspiration for our purpose, because during it the tension of the abdomen lessens. At last we uncover the belly and apply percussion. If pressure on the upper part of the abdomen causes an expression of uneasiness, and some difficulty in respiration, we must be aware of this circumstance as perhaps proceeding from an affection in the chest. We must not forget also, that large pleuritic exudations push the liver or the spleen down into the abdomen, sometimes to the extent of about two inches below the limit of the ribs. It is sometimes only by percussion we can get exact information about abdominal disorders. Dull sound in the lower and lateral parts is the symptom of the collection of the liquid, either transudation, or suppuration. In these

cases there is almost always about the upper regions of the belly, a clear tympanitic sound, able to veil the real affections, if we are not careful in percussing all points. Flatulence or tympany gives a clear sound on the whole extent. Bloated or tympanitic abdomen is proper to gastric or typhoid fevers; sunken or collapsed abdomen belongs, in preference, to cerebral transudations. This alternative holds in the great plurality of cases.

If we find the *temperature* of the abdomen the most elevated of the whole body, we may conclude on a gastric affection, inflammation in this cavity, or a fever with gastric character.

It is needless to mention local affections of the navel, or some other easily perceptible and intelligible external complaints.

Every practitioner will inquire into the state of the abdominal functions, and value the information which he can get; but vomiting and diarrhœa, as physical phenomena, concern in particular our present purpose.

In *sucking children vomiting* occurs frequently; and if there is not any other disturbance joined to it, it has no serious signification. But as vomiting is frequently the symptom of real disorders, we must consider the quality of the ejected matter.

Saburral acid matter, composed of undigested milk or food mixed with different secretions of the stomach and of the liver, is the most frequent kind of vomiting in sucking infants, containing more or less of coagulated or imperfectly digested milk. It becomes more or less frequently repeated in digestive disorders, but is also sometimes apparent at the commencement of acute affections.

Bilious vomiting is rare in little infants, but more frequent in children. I observed it many times at the commencement of acute fevers, particularly in the eruptive; at the commencement of pneumonia or pleurisy, and in true inflammatory meningitis. In this latter case we find the abdomen in a more collapsed state, than in the former.

Mucous vomiting, consisting of more or less consistent clots, is peculiar to catarrhal affections, and frequent in bronchitis or broncho-pneumonia.

Serous vomiting, very liquid, containing mucus, succus gastricus and serum, sometimes a proportion of bile, is one of the symptoms of hydrocephalus, connected with a very collapsed abdomen.

These are only outlines; and only as such I beg you to consider what I am now proceeding to say about some qualities of diarrhœa.

1. The *yellow* discharge. I mention it as the regular kind of stool in infants. It is a mixture of intestinal secretions with bile. As children advance in age, and begin to take substantial food, the colour of their regular discharge becomes more and more of a light brown colour.

2. The *mucous* discharge. White mucous matter, more or less thick or liquid, and mixed with serum, sometimes with a proportion of bile. This discharge is preceded by but moderate pains, and frequently by no pains at all. It denotes a catarrhous, sub-inflammatory, or irritable state of the intestines, and is almost always of local, and not of sympathetic, origin; in general it is not dangerous, and at its commencement is easily manageable by opiates, warm poultices, and convenient hygiène. If neglected, it becomes pertinacious and severe, and not seldom connected with swelling, softening, or granulous luxuriation of the mucous membrane, or ulceration of the follicles. If stripes of blood are mixed with the mucus, and pain be present, it denotes a higher degree of inflammation, in particular of the follicles. The highest development in this direction constitutes enteritis or colitis (dysentery).

Sometimes we find among the mucus, consistent *plastic concretions* of a more or less tubular shape, similar to those of laryngeal croup, but larger in proportion to the volume of the intestines. This is the strongest degree of the catarrhous process, which I might term the *croup of the intestines*. Among the whole number of my little patients, which may be about 30,000, I met with this discharge perhaps only twenty or thirty times. The discharge is effected with very painful efforts at a stool.

3. The *serous*. In general, after more or less severe pains, the discharge takes place with a certain rigidity and noise, after which the pains lessen or subside. It consists of an abundant quantity of serous liquid, dirty whitish, yellowish, or greenish, as, besides mucus, bile is the most common mixture with the serum. The serous diarrhœa is commonly the effect of rheumatism in the peritoneum, in the serous and fibrous membranes, or in the nerves of the intestines. I found in these cases the abdomen very hot. If a great deal of mucus and some blood are mixed with the serum, we may suspect parenchymatous enteritis; if the serous membrane alone enters into the state of acute inflammation, frequently transudation takes place on its free surface.

I have seen cases of profuse serous discharge, in a very short time, even in less than twenty-four hours, produce collapse and death, and in some of these instances necroscopy could not discover an adequate alteration either in the mucous or in the serous membrane.

The serous species of discharge is frequently merely a product of sympathetic secretion. I observed it sometimes connected with large transudations in the chest, and with chronic hydrocephalus.

Speaking in general, serous diarrhœa, if even arising from rheumatism, is more difficult to manage than the mucous. Very minute doses of calomel, with Dover's powder and mustard poultices, are frequently beneficial.

Pure serum, like rice-water, is a less favourable quality than the dirty-white or yellowish. Dark-brown serum frequently denotes a disorder in the portal system, present in some severe gastric or typhoid fevers, but I have seen a similar quality also in chronic affections of the brain, and very frequently in scrofulo-impetiginous children. This is worthy our attention, in particular if eczema or impetigo has disappeared from the head and face. This brown and fœtid discharge accompanies sometimes the commencement of chronic hydrocephalus. I treated it successfully, in this last case, with high but very diluted doses of iodide of potash.

4. *The green bilious discharge.* If pure bile, then the voided matter is in general not abundant; in young children it is of a more yellowish than green colour. The essential character of bile is, to be *of a greenish colour* (in infants it is voided green) *at the very moment of its evacuation.* This kind of discharge is very frequently present in acute inflammatory and febrile affections; if dependent upon an affection of the brain, then we may find the colour to be rather brown, and the abdomen retracted. If a similar source produces abundant serous-bilious discharges, then we find the abdomen much collapsed. But I must observe, acute affections of the brain are almost always connected with constipation, only in some cases of chronic hydrocephalus I met with the mentioned diarrhœa. Bilious discharge, as arising from bilious fever, or from derangement of the liver, is rare in young children. In this case the right hypochondrium will be more or less bloated up. We must be careful not to confound the green bilious discharge with the following:—

5. The *discharge, like chopped eggs,* mixed with mucus, some clots of bile, and caseous coagula of indigested milk, or other kind of food, accompanied almost always by gripes and flatulence; its smell is disagreeably acid, and the whole matter, some minutes after being discharged and *exposed to the atmosphere becomes green.* We know not exactly the chemical change which produces this colouration, it seems to be an oxydation of some of the elements. Then the essential character of this discharge is, that it is yellow at first, and becomes green by exposure to the atmosphere, whilst bile is green at the moment it comes out. I shall call this *the acid saburral discharge*, which is the most obvious before the sixth month of age, in particular if the sucking child takes, besides the milk, some farinaceous food. Practitioners commonly prescribe in this case rhubarb, with magnesia. For my part I prefer, in tender infants, to rely more upon a convenient change in the diet, and as a remedy, aromatic frictions of the epigastrium, and internally bicarbonate of soda, dissolved in mint water.

6. The *bloody discharge.* Pure red blood is seldom discharged by children; in some rare cases I have seen half or one table-spoonful come out, as the product of active congestion and hæmorrhage. Very frequently, on the contrary, blood is combined with the mucous discharge, and in this case, if it is preceded by pain, without tenderness, it denotes an inflammation in the upper parts of the intestinal tube, at least not near the rectum. Tenesmus signifies that the seat of the inflammation is in the lower parts of the colon, or in the rectum. This form is commonly called *dysentery*, not dangerous, if it is without bilious complication and fever, and if treated in its early stage with Dover's powder, some doses of castor oil, and warm poultices; in a stronger degree leeches at the anus; but if neglected in the commencement, it becomes dangerous to the life of the child. Professor Rokitansky, of Vienna, describes most exactly what he calls the "dysenteric process," in three gradual degrees of anatomical change. The highest degree, presenting a dirty red and grey marbled surface, with considerable thickening, granulation, and ulceration, I never saw in the tender age. Young children die before this stage is developed.

Passive hæmorrhage of the intestines very seldom occurs in children. I have seen, however, some cases where, without adequate pain, a considerable quantity of dark thin blood was discharged. Lastly, we have seen in this town, with Mr. Wilson, a case in a child six years old, where, during the course of a gastro-typhoid fever, more than one pint of carbonized blood was discharged in two days. The case recovered. The boy is affected with an enlarged spleen.

Moderate quantities of red blood, discharged without pain, frequently occur, mixed with mucus, and are, without signification, sometimes even connected with the advance of recovery from gastric affections. This is the same case as with epistaxis.

Golding Bird and Simon state, as the result of chemical analysis, that some dark green stools of children owe this colour to blood which has suffered a certain chemical change; but those chemical inquiries are not yet arrived at a satisfactory exactness; we do not even know exactly what kind of green discharges were the subject of these inquiries.

7. *Calomel stools.* Green, more or less thick, or mixed with serum, and in this case more abundant, produced by full doses of calomel. Calomel stools resemble bile, and contain much bile, but they contain also some particular chemical elements which we do not exactly know. In many instances it happens that the calomel diarrhœa commences some days or weeks after the use of mercury, and we must be aware of this, and not confound it with the primary bilious discharge. In the former case the region of the liver is in general softer than in the latter. A clever practitioner will never try to stop directly, and with astringents, a green discharge, whatever be its origin and nature.

Calomel stools contain sometimes blood. After what I have seen in dissection, I incline to attribute this circumstance to a sub-inflammatory state, with superficial erosions of the mucous membrane, which sometimes take place in children after the continued use of calomel.

Once more: I beg to intimate that, I consider all these qualitative and physical distinctions of the discharges of children as very imperfect outlines of a sketch, which by farther physical and chemical inquiry can, and I am sure will, become corrected and perfected. There are, infinitely numerous modifications and combinations, conjunctions of the forenamed qualities. The serous discharge itself offers very manifold colours, which I am not able to bring before you in a well digested diagnostical form; I think, however, the intelligent practitioner will be able to derive some advantage from the principal qualities of the diarrhœa of children already described.

On the next occasion we shall speak of the urine.

CASES IN MIDWIFERY.

By THOMAS RADFORD, M.D., F.R.C.P., Edin., &c., &c., &c.

Consulting Physician to the Manchester and Salford Lying-in Hospital.

In order that the readers of the *Provincial Medical and Surgical Journal* may fairly judge as to the truth of the deductions which I shall hereafter draw from the facts contained in the five cases of Cæsarean section in which I have been concerned, I deem it desirable to insert two cases, (which have been already published,) in this Journal.

Case III.

Cæsarean Section.—*(Successful.)*

This case was read at the anniversary meeting of the Provincial Medical and Surgical Association, at Worcester, August, 1849, and afterwards printed in the next number of the *Journal*. In a letter received from Mr. Cheley, since the case was published, he says that he now believes "that the fluid was from the bladder," and not a partial discharge of the liquor amnii, as reported. If the reader refers to the statement as mentioned to be made to me when I first visited the patient, he will find it is said that the membranes were unintentionally ruptured during a vaginal examination. Whether so or not, it makes no difference as to the truth of the inference I then drew from it.

Case IV.

Cæsarean Section.—*(Unsuccessful.)*

On Sunday, the 1st of April, 1820, I was requested to visit Mary Ashworth, residing at Denton, about six miles from Manchester. I was told she was in great danger, having been in labour a considerable length of time, and that no progress was made in the case. This report did not surprise me when I ascertained who the individual was: for Mr. Wood, my partner and esteemed relative, had visited her about the end of the seventh month of her present pregnancy, at the request of her medical attendant, Mr. Morris, a highly respectable surgeon, who resided at Ashton-under-Lyne. Mr. Wood at this period examined her *per vaginam*, and his opinion was, that if her pregnancy did proceed, when labour came on, the Cæsarean section would be required, as in her case no other means would be of the least avail. At three o'clock, P.M., I reached her dwelling, and found Mr. Morris and Mr. Cheetham awaiting my arrival.

I was informed by Mr. Morris that she had been in strong labour about thirty-four hours; that the membranes had ruptured in two hours after its commencement, and that the *liquor amnii* had gradually passed away. He had not been able to feel the presentation nor the *os uteri*. The pains were strong for twenty-four hours, but afterwards gradually abated. The urine had been passed freely during the Saturday; but this day (Sunday) there was no evidence of any having been discharged. The bowels were constipated, and had not been opened during the labour.

Her previous history was to the following effect:—She had borne ten children, nine of whom were expelled by the natural powers. In the last labour considerable difficulty occurred, and the practitioner had recourse to craniotomy. During her tenth pregnancy she experienced considerable weakness in her loins, and felt rheumatic pains about the hips, and limped in her gait. These pains continued from that time till her present pregnancy, but did not increase in degree. When she became again pregnant her sufferings increased, and her lameness became more manifest. Her stature was now observed to diminish in height. She was 42 years of age, and was employed as a hat-trimmer.

I found her in bed lying upon the back, with the head and shoulders raised. She moved with the greatest difficulty. The pulse was feeble and frequent, beating about 150 in the minute. She had often vomited, and had great tenderness in the belly, which was considerably increased by pressure. Her tongue was furred and dry, and she complained of great thirst; her countenance expressed considerable anguish. Being requested to compose her mind, she answered, "she was composed, but anxious for relief, and would suffer any pain so that she might be delivered."

Upon examining the abdomen, I found the uterus projecting very much forwards, and lying with its anterior surface upon the upper part of the thighs. By a vaginal examination I discovered that the labia were much swelled, and the vagina felt dry and rough; it was hotter than natural; and an odour similar to that arising from animal matter when partially decomposed was perceived from the hand when it was withdrawn. The outlet of the pelvis had undergone great change; the arch of the pubes was totally destroyed by the near approximation of the rami of the ischia and pubes, having only a small slit, so narrow at the upper and lower parts as not to admit the point of the index finger; at the middle, however, the finger could just be introduced. The tuberosities of the ischia were not more than one inch and a half to one inch and three-quarters asunder; and the lower portion of the sacrum was so much more incurvated than natural, as to throw the coccyx much more forward, and consequently lessen the conjugate diameter of the lower aperture of the pelvis. This great diminution in the outlet rendered it difficult to pass the hand in order to measure the brim, and it was found necessary to carry it very far backwards in order to accomplish it. This aperture was found much more altered than the outlet; one finger only edgeways could be placed between the points of bone in the conjugate diameter. In traversing it from side to side I could detect no great difference, but if there was any, the left was the most contracted. In the transverse diameter I could just place three fingers parallel to each other. The figure of the brim was tripartite, having a slit on each side; and a third passing forwards, produced by the approximation and jutting out of the pubes, which was so narrow that the finger could not

pass within it. This alteration in the brim was occasioned by the falling downwards and forwards of the upper part of the sacrum, and the lower lumbar vertebra, and by the body of the *ossa pubis* and ischii being forced backwards and inwards, whilst the symphysis and rami of the pubes projected forwards and upwards. The measurement of the conjugate diameter did not exceed three-quarters of an inch, or that of the transverse two inches; and having placed my fingers upon each other in the widest part, and having measured them when withdrawn, I concluded that no body of a diameter greater than from three-quarters to one inch could pass through it; and that delivery *per vias naturales*, aided by the crotchet, was utterly impracticable. Another important feature in the case was, that no part of the child or *os uteri* could be felt.

Upon these grounds, then, we concluded that our only resource was the Cæsarean section. Our opinions were now stated to the husband and friends, and they cheerfully submitted to any practice we thought best to adopt. The patient, anxious to have her sufferings terminated, also readily acquiesced in our decision.

An enema was ordered to be administered, and it soon operated. The catheter was also introduced, but little urine was withdrawn. As the patient felt cold, a little warm wine and water was given, which acted beneficially. Having placed her upon a table, an incision of six inches long was made through the abdominal integuments about one inch to the left of the umbilicus, extending from three inches above to three below. A small opening was made into the peritoneum, and this membrane was afterwards fully divided by a probe-pointed bistoury. The uterus was now exposed, and an excision of equal length was made into this organ, nearly dividing its entire substance. An opening was now made at the lowest point of the wound by the knife, so as to admit the finger, upon which the bistoury was again passed, and the uterus was laid open. I now passed my hand, and, taking hold of the thigh of the child, readily extracted it; but, unfortunately, it was dead. The funis having been divided, the placental portion was held firmly in the left hand, whilst the right was introduced into the uterus to extract the placenta, which was attached to the upper and posterior part of the uterus. As soon as the placenta was removed, the uterus energetically contracted, and lowering itself became almost invisible. The intestines protruded at the wound, but were soon reduced and retained by the hands extended over their surface. Mr. Morris next passed several ligatures through the abdominal parietes, and afterwards applied slips of adhesive plaster, by which the edges of the wound were closely approximated. Pledgets of lint, spread with cerate, were also applied, and in order to secure the whole a broad bandage was loosely put on. The quantity of blood lost was trivial, not exceeding three or four ounces, which favourable circumstance, doubtless, was partly owing to the position of the placenta, and partly to the vigorous contraction of the uterus.

During the whole course of the operation the patient maintained the greatest fortitude, and expressed her thankfulness upon the termination of her sufferings. She, however, as well as all present, was disappointed that the child was lost.

The patient was then put to bed, and, as the pulse was rather low, a cordial was administered, which in a little while revived her. An anodyne draught, containing 60 minims of laudanum, was also given.

At ten o'clock, P.M., the pulse was 140; the skin was hot; she was thirsty, and complained of headach; belly tender; discharge not more than usual; thinks she can sleep; no urine passed.

April 2nd.—Eight o'clock, A.M.—Says she has slept; has taken some refreshment; skin hotter; pulse 140 to 150 in the minute, and feels sharp to the finger; has not voided any urine; bowels not moved. Ordered saline effervescing draughts. The catheter to be introduced, by which from three to four ounces of urine were withdrawn.

Twelve o'clock, noon.—Not so well; had shivering and some vomiting; the pulse was more frequent; and the abdominal tenderness increased; belly swelled; a sanious discharge was oozing from the wound; bandage uncomfortable; vaginal discharge rather greater and more offensive; bowels not moved. The medicines were continued, and the bandage loosened.

Four o'clock, P.M.—Has again shivered; continues to vomit; pulse more frequent and tremulous; countenance more depressed; abdomen more tender and more swelled; is very thirsty; and her tongue is very much loaded; the bowels still constipated. The saline medicines were continued, and an enema with oil of turpentine and castor oil was ordered to be administered.

Ten o'clock, P.M.—Vomiting continues unabated; pulse still very frequent and much weaker; skin colder and rather clammy; is slightly incoherent; belly very tender and much swelled; discharge offensive; has not passed urine; the enema operated. The catheter introduced, and four ounces of urine withdrawn; the bandage still further loosened; to have a little brandy in her gruel; to take forty minims of laudanum. The symptoms continued to grow more unfavourable during the night, and she died at four o'clock this morning (Tuesday) about thirty-five hours after the operation.

An application was made to examine the body, but permission was only granted under a promise that the wound was alone to be inspected; but Mr. Morris while alone took the opportunity of ascertaining, as far as he was able, the state of the parts. The edges of the external wound were quite separate, and had a flabby unhealthy aspect. Having divided the stitches, and drawn aside the integuments, the uterus was observed to be well contracted. The wound was much diminished, its edges were loose and unhealthy. The peritoneum was inflamed, and about from four to six ounces of serum were effused within its cavity. Upon again raising the uterus, the cervix was seen to be dark-coloured, and having divided it, the lower portion and orifice were found in a gangrenous state. The bladder was empty, and uninjured. The brim of the pelvis was examined, and found fully as much distorted as I have before mentioned.

Remarks.—The issue of this case presents indisputable evidence of the serious mischief arising from protracting the operation. Both the life of the mother and the child were most likely forfeited by the delay. How the real character of the case could have been so much overlooked, after the clear and decided opinion of Mr. Wood, given at the end of the seventh month, I am at a loss to conceive.

The tumefaction of the external genitals, and the inflamed condition of the vagina, are alone to be attributed to the too frequent examinations made. When a practitioner undertakes to explore for the exact measurements of the brim of the pelvis, deformed like the one belonging to the subject of this case, he is compelled to pass his hand completely into the vagina, and, from an anxiety to accomplish this, and to ascertain the nature of the presentation of the child, he is induced to repeat the operation very often. These repeated examinations are often productive of very serious mischief, causing inflammation, which frequently terminates in suppuration and sloughing. With these circumstances before us, we are of opinion that every unnecessary manœuvre ought to be avoided, and that the practitioner should acquaint himself, as completely as it is possible, with the nature of the case, before he withdraws his hand.

Case V.

Cæsarean Section.—(*Unsuccessful.*)

Mary Nixon, aged 39, had been married sixteen years, and had been pregnant eight times, in seven of which she reached the full period of gestation, and in one she miscarried once at the fourth month, which happened about thirteen months before her present pregnancy. The last natural labour took place about four years since, and was so rapid as to be completed in two to three hours. She had enjoyed good health until about two years ago, when she began to suffer from what she called rheumatism and a short cough. Afterwards she was frequently confined to bed, and her friends observed her to rather diminish in height. The pains in her back and hips increased in violence during her present pregnancy, and her height is now very considerably diminished. She has been employed as an "ender and mender" for the manufacturers, which occupation has obliged her to be sedentary, but has attended to her domestic duties, although unfit.

At one o'clock on Thursday morning, May 24th, 1821, she was apprised of the approach of labour by a discharge of water, which continued to dribble away without pain. At four o'clock Mrs. Barber, her midwife, was sent for, as she now felt slight pains. On examination *per vaginam* Mrs. B. could neither feel the *os uteri* nor any part of the child, but ascertained that the pelvis was considerably distorted. At noon she sent for Mr. Wilson,* one of the surgeons of the Manchester Lying-in Hospital, but he was from home, and instead of immediately applying elsewhere, she allowed several hours to elapse before she sent for other assistance. At eight o'clock, P.M., Mr. K. Wood saw the patient, and considered the case of such importance as to induce him to call upon Mr. Wilson, who was then at home, and they immediately went to the house, and reached it at a quarter before nine o'clock. Mr. Wilson agreed in his opinion, and he desired that a general consultation of the medical officers of the institution might be immediately called.

At ten o'clock, P.M., when Dr. Hull, Mr. Wilson, Mr. K. Wood, Mr. Lowe, and Dr. Radford had assembled, the state of the patient was as follows:—Her pulse was 130; the skin hotter than natural; her tongue was furred; she was very thirsty; her countenance was cheerful; she had passed urine at several intervals during her labour, and her bowels had responded three times to an enema which her midwife had very judiciously administered. The stools were scanty, and of a green colour. The pains, which were reported to have been very frequent during the afternoon, continued so. She complained of great tenderness in the belly, which was considerably increased by pressure. The distance between the pubes and sternum was much shorter than natural. The *fundus uteri* projected very much forwards, and had an inclination to the left side. By an examination *per vaginam*, I found the parts soft, moist, and cool. The sacrum was considerably more incurvated than natural, and the coccyx projected upwards into the cavity of the pelvis. The tuberosities of the ischia approached very near together at the fore-part, and the rami of the ischia and pubes approximated so closely together as not to admit a finger to pass between them along any part, except at the middle, at which place there was a small opening, in consequence of a slight bulging outwards of the bone on either side. The pubic arch was destroyed, and only a small chink left, by which the depth of the pelvis was increased at the anterior part. In order to examine the brim I passed my hand, but was compelled to carry it very much backwards. The pubes on each side formed a very acute angle at their fore part, and then running forwards nearly parallel to the symphysis, having a slit between them which would barely admit the finger edgeways. The base of the sacrum and the last lumbar vertebra had sunk forwards and downwards into the pelvis, and diminished the conjugate diameter on the left side so much as barely to admit the finger in the position, that when it was withdrawn, it measured three-quarters of an inch, and when placed in other parts of the brim, an inch, as far as could be ascertained, was the fullest latitude which could be given to guide us in our decision. We all agreed that no other means but the Cæsarean section could avail us to deliver this poor creature.

Having decided upon our plan, we stated our opinions to the friends, who readily consented that we should adopt any practice we thought best. When we acquainted the patient with the difficulty of her case, and the operation necessary to extricate the child, she

* It is with the permission of my respected friend, Mr. Wilson, that I am enabled to publish this case, and I beg to thank him for his great kindness, more especially for his liberality in furnishing me with what few notes he had taken of the case, all of which are in accordance with my own.

unhesitatingly acquiesced. It was intended to have used the catheter, but this was unnecessary, as half a pint of urine was discharged by her own efforts.

She was now placed upon a table, and a little brandy and water, with thirty drops of laudanum, was administered her.

Mr. Wilson made a longitudinal incision a little to the left of the umbilicus, six inches in length, extending from three inches above to three inches below this part, and divided the abdominal parietes down to the peritoneum. A small opening was made through this membrane, and it was fully divided by a probe-pointed bistoury, passed along with the finger. An incision was now made nearly through the uterus, corresponding in length and direction to the external wound. The probe-pointed bistoury was introduced on the finger through a small opening, and the remaining portion divided. This exposed the child, which lay with its breech towards the opening. Mr. K. Wood seized the child by one thigh, and the body was extracted with the greatest ease, until the shoulders came to pass, when the uterus suddenly and powerfully contracted, and grasped the child's neck and left arm so strongly that this gentleman could not liberate it, although he used great force in extraction. He then gradually passed his hand along the body of the child into the uterus, and having dilated the structure the child was extracted. It would have been easier to have torn away the uterus from its connections than to have brought the child away by direct extractive force. The fundus and body of the uterus felt very hard. The child was vigorously alive when first taken hold of, but from the length of time occupied in extracting the head, it became so enfeebled as to show only slight signs of life. I very diligently employed every means to resuscitate it, and continued them for at least three quarters of an hour, but was ultimately unsuccessful. This was a most appalling affair. After dividing the funis, the placental extremity was firmly held with one hand, whilst the other was introduced into the cavity of the uterus, for the purpose of removing the placenta, which was already detached, and lying loose. The uterus then immediately fully contracted.

The intestines, which appeared at the wound, were replaced and retained by the extended hand; the edges of the wound were then brought together by ligatures, supported by strips of adhesive plaster and an extended bandage.

Very little blood was lost during the operation, a small branch of the epigastric only being divided. Its bleeding was restrained by the pressure of the finger.

The patient felt faint whilst on the table, but was soon recruited by taking a little brandy and water. When all was adjusted she was carried to bed, and said she was quite as comfortable as she could possibly expect. The pulse now beat about 136 in the minute, and was distinct. The heat of the skin was not much above natural. In half an hour afterwards she felt a distressing sensation at the chest; her heart beat very quickly, and the breathing became very much hurried; her skin grew cold, and the vaginal discharge was increased, but still not in such a quantity as to create alarm. Thirty drops of laudanum in a little brandy and water were immediately administered, and in half an hour forty drops more. In a very short time all these symptoms subsided, and she felt as well and as warm as before. All stimulants were now prohibited, and the antiphlogistic regimen recommended, and she was left for the night in the charge of Mr. Hunt, at that time a pupil of Mr. Wilson's.

Friday, May 25th, seven o'clock, A.M.—Present, Dr. Hull, Mr. Wilson, Mr. K. Wood, and Dr. Radford. She experienced no further palpitation of the heart; slept tolerably well; the pulse was 131; respiration easy; skin rather hot; belly feels comfortable and not swelled. To take a saline effervescent draught every three hours, and an ounce of the almond mixture with five drops of laudanum in the intervals.

Twelve o'clock, noon.—Present, Mr. Wilson, Mr. Hudson, Mr. K. Wood, and Dr. Radford. The heart appeared to jerk; pulse 130, and quite distinct; skin hotter; her countenance more anxious; tongue furred, but moist; has again slept; urine passed twice. The medicines were continued.

Four o'clock, P.M.—Present, Mr. Wood, Mr. Wilson, Mr. K. Wood, and Dr. Radford. Belly rather tense; pulse 130, and firmer; tongue dry and furred; is thirsty; has passed urine; her cough is still troublesome; the bowels are constipated. A solution of Epsom salts in infusion of roses was directed to be given until it operated, and a linctus for the cough was ordered.

Six o'clock, P.M.—Present, Dr. Hull, Mr. Wilson, and Dr. Radford. Her countenance looked better; the heart throbbed violently; her pulse beat 125; the tongue was rather more moist and soft; the belly continued very tense; and the respiration was hurried; she has had slight vomiting, and her bowels have not yet been moved. The medicines were continued.

Ten o'clock, P.M.—Present, Mr. Wilson, Mr. Lowe, and Dr. Radford. Her countenance has become more anxious; her respiration is more laborious, and she has again vomited. The skin is hotter; her belly is very tender, and is much swelled; her pulse is 130; the vaginal discharge trifling, and very slightly coloured; she has a tendency to dose; has had several fœtid liquid stools.

To omit the aperient, but to continue the other medicine; the bandage to be loosened.

26th, Saturday, eight o'clock, A.M.—Present, Mr. Wood, Mr. Wilson, Mr. K. Wood, and Dr. Radford. Has frequently vomited a brown slimy fluid; her pulse is 130; her respiration still laborious; the belly rather softer; her skin is still hot; and the lochial discharge very trifling.

Ten o'clock, A.M.—Present, Dr. Hull, Mr. Wilson, and Dr. Radford. Pulse 134; vomiting has ceased.

One o'clock, P.M.—Present, Mr. Wood, Mr. Wilson, and Dr. Radford. Her hands feel cold; the pulse is 130; her mind is clear; the vomiting has ceased; lochial discharge fœtid and more profuse; and there has been a thin and offensive sanious discharge from the wound.

Five o'clock, P.M.—Symptoms still grow worse.

Ten o'clock, P.M.—Present, Mr. Wood, Mr. K. Wood, and Dr. Radford. The symptoms continue to become more unfavourable.

Sunday, eight o'clock, A.M.—Pulse 140, and very weak; the skin is rather cold, and covered with a slight clammy sweat; her countenance is very anxious; and there is great swelling and tenderness of the belly; the lochial discharge is very offensive; she has not passed urine. The lowest strap of adhesive plaster being removed, the wound appeared in an unhealthy state and not united; a great discharge took place, which was very offensive. During this day (Sunday) she was visited several times, and found still further sinking. At six o'clock in the evening she expired, having lived sixty-seven hours and a half after the operation.

Remarks.—It may appear strange that no notice was taken of this poor woman's case at an earlier period of pregnancy, as she was a patient of the Lying-in Hospital. But our hospital extends its aid only to poor women at their own houses; and this poor creature having obtained a note of recommendation from a subscriber, was admitted, the medical officers having no knowledge that such a case was on the books. Another unfortunate circumstance was the midwife omitting to send for other surgical assistance in the absence of Mr. Wilson, thereby allowing several valuable hours to elapse.

The violent contraction of the uterus, by which the head and left arm of the child were seized after the extraction of the trunk and lower extremities, forms a remarkable feature in the case. The placenta was found detached and lying loose in the cavity of the uterus; and how far this violent contraction depended upon this circumstance is difficult to say. In natural labour we well know that as soon as the placenta is detached, the energies of the fundus and body of the uterus are aroused, and contraction follows, and is continued until this mass is expelled. In the former case of Cæsarean operation the uterus was quiescent, until the placenta was detached by the hand, when contraction instantaneously followed.

TWO CASES OF INSANITY,

ILLUSTRATIVE OF THE UNCERTAINTY OF DIAGNOSIS BASED ON PHRENOLOGICAL INDICATIONS.

By HENRY LANDOR, Esq., M.R.C.S.,

RESIDENT PROPRIETOR HEIGHAM RETREAT, NORWICH.

Case I.

A. B., aged 50, in February, 1849, was thrown out of his gig, and kicked on the forehead, over the left superciliary ridge, the wheel of the gig also injuring the right superciliary ridge, but there does not appear to have been any fracture or injury of the bone. Since that time his mind has gradually deteriorated, as first shown in the want of his usual acumen in matters of business. From having been a ready accountant, he began to be unable to add up a simple arithmetical sum, making many and great mistakes. From having been methodical and regular in his habits, he became careless and irregular, fretful, irritable, fearful and timid, thinking every one who approached him meant to hurt him, and latterly he thought it wicked to eat, because he imagined himself too poor to afford himself food.

Such was his state of mind on admission, July 10th, 1850. His body was much emaciated; the expression of his countenance was that of fear and distress; his tongue was parched and dry, but he could not be induced to moisten it; his pulse was 120, and feeble. A year before he had had hæmoptysis, and other pulmonary symptoms, a short cough with expectoration. He had passed the last winter in Devonshire. In March last his cough left him.

July 13.—He has been fed with spoon or feeding cup three time a day; he can hardly be induced to make water, but on threatening to draw it off he passed a large quantity; often retains it for thirty-six hours; he will not swallow food, nor try to have a motion, which operations he says are certain death to him. I have given a convenient purgative in his food. On examining his chest by the stethoscope, I find tubercles in his right lung extensively, and in the left slightly; a mucous râle in the larger bronchial tubes; he sleeps well, and would eat if he could believe it right to do so. The abdominal viscera are healthy.

July 20th.—He has been fed thrice daily with a spoon, and sometimes with stomach pump. It has been necessary to use the catheter twice daily, and to give an occasional purgative, solely because he will retain those evacuations even when he suffers pain from doing so; he rests well, and has no physical symptoms referable to the head; his ideas are very deranged; he has no notion of number, fancying he has taken food many times oftener than is the case.

July 30th.—Still fed daily, and daily getting weaker.

August 2nd.—He died this morning, quietly and gently.

August 3rd.—*Post-mortem.*—Body much emaciated; scalp adherent; dura mater strong but not diseased; skull not thickened; arachnoid, opaque, milky, vascular; much serous effusion, (doubtless due to the last few hours of life); brain soft; vesicular neurine pale and pulpy; brain adherent to the membranes near the falx; opacity, extending over the anterior lobe, and anterior portion of the middle lobes of the brain, and into the convolutions; arachnoid lining the ventricles opaque, mostly so in the left ventricle; roughened to the feel; at the base of the brain in a similar state; the lateral convolutions pale and flabby; at the base less so; the tubular neurine healthy; adhesions of the right pleura; lung studded with tubercles, more so in the right than left lung; cavity posteriorly in the right lung; hepatization; heart soft, pale, flabby; other organs healthy.

In this case the mental disease first shewed itself

after the accident, and its first manifestation was merely an inability to accomplish the commonest arithmetical sums; next there appeared an irregularity of habit, instead of an accustomed habit of order; then timidity; then a fear of poverty; after that an idea that it was wicked to eat, when the means of payment were wanting; and lastly, a wish to die, to release his friends from the cost of his maintenance. In the language of phrenologists, the organ of number, immediately under the injury produced by the accident, was the first affected; then order, then cautiousness, then acquisitiveness, then veneration, and lastly, alimentiveness and love of life. Here I wish to draw attention to the consecution of the symptoms, which must have been produced by the gradual spread of the arachnoid inflammation from the anterior lateral portion of the cerebrum backwards, and towards the base of the brain; and let me point out how remarkably the diseased manifestations of the organs corresponded with the extent of the arachnoid thickening, and the diseased state of the vesicular neurine. There was no disorder of the animal, or of the posterior moral, organs; and there was no disease of the arachnoid, or the vesicular neurine, beyond the anterior half of the middle lobes of the cerebrum. One thing seems probable: that if this patient had been put under the influence of mercury in the earliest stage of his disease, he would possibly have recovered; but it is by no means clear that there was any symptom sufficiently prominent to induce any rational practitioner to proceed to so active a measure as the use of mercury to the extent of salivation. It must be remembered that the only symptom was a diseased idea, there were no physical symptoms; and it must be admitted that phrenology is by no means so certain a science as to enable its votaries to predicate the exact nature of the morbid change from the diseased manifestation. The organ of number might have been disordered just as well from a change in the tubular neurine, which conveys, and enables the individual to manifest the idea originated in the vesicular neurine. In short, the most ardent phrenologist will admit, that as yet it is impossible to found any safe treatment upon phrenological symptoms alone. I record this case because of its interest phrenologically, and because it is useful to have such cases known, that other observers may add their facts to this fact, in order either to lay the foundation of treatment based on phrenological indications, or else to show its uselessness, as the event may happen. I would further draw attention to the entire absence of all head symptoms. It is somewhat interesting to remember, that with the absence of symptoms referring to the head, the patient never had one calm, natural, night's sleep, until insanity became well marked. That is, I suppose, while the disease was confined to the arachnoid; the state of the vesicular neurine was one of irritation and excitement, which prevented sleep; but when the vesicular neurine became more diseased, and less susceptible to irritating impressions, less capable, in fact, of performing its proper functions, sleep returned. I look upon the phthisis as an accidental complication, though, probably, the tubercle development was encouraged by the low tone of the nervous energies, consequent upon the accident. The slow progress of the disease, (a year and a half), the absence of bodily suffering, the extent of the morbid alteration, and the peculiarity of the mental aberration, make the case interesting.

Case II.

D. C., admitted into the Retreat on the 8th of June, 1849, aged 44, single, has been ill six months, at first with hepatic disturbance, but except that she was rather desponding she exhibited no symptoms of mental disease. A gentle mercurial course, with taraxacum, completely restored her, and she pursued her customary occupation as a domestic servant up to the beginning of April, when her old symptoms reappeared, accompanied by great irritabilty and decided mental aberration. She threatened suicide. On her admission, it was stated by her friends, and also on the face of the certificate, that she had taken no food for several days. She was extremely emaciated; breath fœtid; pulse 72, very languid; bowels costive; countenance anxious; tongue whitish; sleeps well; head cool; has the most invincible objection to any measures likely to benefit her. For the first two days she was fed with the spoon, but subsequently her resistance was so great as to require the œsophageal tube, which has since been employed regularly three times a day. Calomel was administered occasionally, and sulphate of quina twice a day; this was subsequently changed for infusion of gentian with carbonate of soda, and hydr. c. cretâ every night.

June 29th.—Emaciation extreme; tongue aphthous. She takes arrowroot and milk, with a little brandy, morning and evening, with arrowroot and soup at dinner.

July 30th.—During the whole of this month she has been fed thrice daily. Her general health and state of bowels are improving, but her obstinacy is invincible. She complains of hunger, but says she dare not eat. Seems to have some perverted religious feeling, thinking it wicked and herself condemned as an unconverted sinner.

In August, a slight diarrhœa, which was easily checked. She became stronger and more determined not to eat. In September bed-sores appeared. In October each trochanter was exposed; but she got stronger, and she was still fed with the pump, taking morphine at night. November and December she remained in the same state. In January, 1850, she was placed on a water bed.

It may be briefly stated that she lingered on until the 18th of September, 1850. Her bed-sores healed entirely. She was left without food occasionally, and she ate her food for a day or two in a fair quantity; but she then reverted to her old determination, and at the last moment I was obliged to yield and feed her again. She was tempted by the daily exhibition of food; she was coaxed and frightened into eating a meal occasionally, but she always returned to her old courses, and, although she did eat now and then, she could never be induced to drink, so that she felt the loss of her usual

stimulant—the brandy, which, latterly, was given to a considerable amount. At any time during the past year it appeared that she would have recovered, if she could have been induced to eat, for there was no evidence of disease of any organ. She could at any time converse quite rationally, and her ideas were sound on most subjects, except the persistent idea of wishing to die. Abstinence from food was the way in which she desired to end herself. She swore violently, and resisted determinedly when she was fed. Latterly she would not open her mouth without the use of great force. She was once or twice made to open her mouth by stimulating the digastric muscles with a small galvanic battery.

On the 20th of September her body was examined. She was extremely emaciated; skull-cap natural; the membranes healthy; slight venous congestion; brain flabby and pale, but no trace of altered structure. In fact, no disease could be found in any organ of the body, after a very minute and careful search, excepting a few old adhesions of the right pleura, and a very few isolated tubercles. All the organs were healthy, liver particularly so.

Remarks.—In the first place we will remark on the total absence of disease in the brain and its membranes, and contrast the deranged ideas of this case, which were remarkably similar to those of A. B.; yet in his case there was amply sufficient to account for the symptoms, while in this there were some similar delusions with no disease of structure. What becomes of the phrenological indications—alimentiveness, and veneration, and love of life, quite as much deranged as in the previous case, but no trace of alteration of structure in those organs? It must be confessed that if the other case seemed to confirm phrenology, this as completely sets it at nought.

Notwithstanding, I believe that there is in all cases of insanity structural alteration, but it escapes our imperfect means of detection.

With regard to the mode of feeding adopted in this case, there is little room for two opinions. We hear a great deal of the facility which some people have of overcoming the obstinate refusal to take food manifested by insane patients; but in this case all means of persuasion and all modes of administering food were tried before it was found absolutely necessary to employ the stomach pump. It is true that in very recent cases, where the patient retains some amount of bodily strength, artifice is often successful, such as strong exercise, exciting hunger, and then making a companion or an attendant eat in the patient's presence. Often, also, by the administration of opium until unconsciousness ensues, and in that state placing food in the mouth, it is swallowed mechanically, and the patient continues eating when sensibility occurs; for, when once the first reluctance to eat is overcome the patient yields without further effort. However, none of these modes succeeded in this case, nor was there any disease of the digestive or other organs to lead to the hope that on its removal her obstinacy would give way. There remained, then, no other resource but mechanical feeding. Although in the former case there was great disinclination to eat, and absolute refusal at times, yet that patient yielded to one or two applications of the tube, and could be fed with the spoon or feeding-cup; but in the last case nothing but force could get a particle of food into the stomach.

There is another case now under treatment, with mental symptoms very similar to the first here recorded, but with a better hope of recovery. I will report it at some future time.

CASE OF

STRICTURE OF THE URETHRA.

By W. JEAFFRESON, Esq., Framlingham.

Read at the Suffolk Branch Meeting, held at Framlingham, June 27, 1851.

I HAVE more than usual satisfaction in directing attention to the case I am about to relate, as, although it occurred fourteen or fifteen years since, I was again called to the patient in July, last year, and therefore can speak positively of its results.

Case of aggravated Stricture, followed by Rupture of the Membranous part of the Urethra, consequent Extravasation of Urine, and Sloughing of the whole of the Integuments of the Scrotum and of the Perineum, exposing the Muscles as if dissected for demonstration.

J. N., a mechanic, married, and with a family living in a parish five miles from Framlingham, and thirteen from Saxmundham, applied to my late friend Mr. King, surgeon, of the latter place, on the 21st of May, 1836, suffering retention of urine from neglected stricture. Being unable to pass a catheter, of the smallest size, Mr. King advised him to drive carefully home, and to send for me immediately. In returning home in a cart, *not very easy*, and over rough roads, the membranous part of the urethra gave way, and the scrotum and perineum became distended with urine, by which he was for a time relieved, and did not send for me till the following day, when the distended parts were highly inflamed and of a dark dusky hue. I at once persuaded him to allow me to make a deep incision into the perineum from the membranous part of the urethra, along the raphé, to very near the sphincter ani externus, which gave exit to a very large quantity of highly offensive matter and urine.

This patient had suffered more than three years from blennorrhœa, during which period he had consulted many practitioners, regular and irregular, and had for many months placed his confidence in Franks' essence of copaiba. There was complete obliteration of that portion of the urethra, embraced by the glans, and it terminated by a morbid opening posterior to the glans, just at the junction of the frænum preputiæ.

Having dilated this sufficiently to admit a fair-sized catheter, I was enabled to carry this down to the bulb, where existed the very narrow stricture which had given rise to the retention of urine, and the rupture of the membranous part. This I was enabled to divide, and to pass the catheter fairly into the bladder. I directed one drachm of sulphate of magnesia in saline draught every four hours, and a spirituous lotion to be applied to the parts affected.

24th.—Complete sphacelus of the scrotum and of the integuments of the perineum, which emitted a most offensive odour; directed quinine and ammonia every four hours, and a solution of chloride of lime (two drachms to a pint) to be constantly applied to the part affected. Visited him in the evening; a liberal allowance of wine, porter, and strong meat broth, and gave him—Tinct. Opii, Spr. Ammon., Arom., sing, m. xxx.; Aquæ, oz. j., horâ somni sumend.

25th.—Withdrew, cleansed, and replaced the catheter, which I continued to do every third day during the progress of the case, there being a strong disposition to calculous deposit. Continue the quinine of ammonia, and lotion of chloride of lime.

26th.—Pulse very feeble, 130. Continue the same plan, with cordial opiate at bed time.

27th.—*In statu quo*, with frequent hiccough; added musk to each dose of his mixture. Continue opiate draught and lotion. The same plan continued to 31st. Line of separation commenced.

June 1st.—Line of separation complete; pulse improved in power, less frequent; hiccough gone. The same plan continued till the 7th, when the sloughs, came away, leaving testes exposed. Continue the same, omitting the musk, but continuing the same liberal supply of wine, porter, and good broth, which he commenced from the first appearance of sphacelus.

13th.—Healthy granulations, and commencing cicatrization. The same plan continued.

August 27th.—Testes covered.

July 27th, 1850.—Requested to visit him in consequence of the closing of the morbid termination of the urethra, causing retention of urine; dilated this sufficiently to admit a catheter, which passed without obstruction into the bladder. He has continued well since.

In conclusion, I may perhaps be allowed to inquire what would have been the result of this case had it been treated on the professed principles of that most cruel of all fallacies—homœopathy? or on the plan recommended by the hydropathists? which, although more powerful, is scarcely less dangerous, and of which it may be said that much is not new, and the greater part of the little which is new is not true, as the more valuable part of the water cure was given us long since by Dr. Currie of Liverpool, Dr. Mason Good, and others; but when men attaching M.D. to their names can become such traitors to their profession, as to accuse regular practitioners of treating every fever patient indiscriminately, by bleeding, purging and salivation, they merit the execration of every honest member of that profession they have so grossly traduced, and when such men pretend to base their fallacies on the principles of such characters as the immortal Liebig, I would refer them to one of this gentleman's published works for his opinion. "The existence of hydropathic institutions—those dens of covetous and rapacious gamblers, where the wretched invalid resorts to throw the dice for health and life; the rise and progress of the homœopathic system, which treats truth with scorn, and bids defiance to common sense, loudly proclaim the need which exists for the adoption of settled principles, definite methods of research, and a systematic arrangement to guarantee their attainment and retention."—*Justus Liebig.*

CASE OF FUNGUS HÆMATODES OF THE BLADDER.

By RICHARD V. GORHAM, Esq., M.R.C.S.

Read at the Meeting of the Suffolk Branch, June 27, 1851.

The subject of this case, J. K., aged 67 years, a bricklayer and master builder, has been a sufferer from very early youth, from an irritable bladder, and also from severe vomiting, which lasted as many as three days when it commenced, but yielded to abstinence from food or drink and effervescent salines.

The irritable bladder increased to the time of his death, and was always aggravated after drinking, and particularly beer, but this combined with gin did not produce so much injury. He also had the gout when young, and twice during his illness. For three years this individual was my patient, during which time he was at intervals under my charge for symptoms of stomach, renal, and bladder affection.

In December, 1850, he was taken with slight hæmaturia, for which he took the gallic acid in five-grain doses, with marked benefit, this drug both restrained the bleeding in a short time, and diminished the albumen, which continued afterwards to show itself. It was required to give him an opiate at night on account of the great pain he felt both before and after passing the least drop of urine.

The distressing sickness noticed in the commencement of my acquaintance with him, never showed itself during his last illness, which would have aggravated his sufferings much. The hæmorrhoids and prolapsus ani were very distressing. During the whole treatment I had to bear in mind his gouty tendency, and to give him alkalies after his food, and the nitro-muriatic acid, diluted with a bitter, and sulphate of zinc before his food, and this for some time seemed to improve the symptoms, but at the end of January, 1851, the bladder symptoms increased in severity. I then had recourse to the infusion of buchu and uva ursi, with soda and soap, and from this time till his death, which took place in April, I made the bladder and kidneys the principal object of treatment.

On March 28th, I find by my notes the first appearance of pus in the urine showed itself. This fluid was

turbid, greater in quantity than it had been for some days previously, very acid, great pain in voiding the least drop, slight delirium, with flatulence and great difficulty of breathing, for which I prescribed Æther Sulphuric c. Sp. Armocaciæ.

29th.—Increase of pus; slight delirium; great pain; no appetite, and great prostration of strength, with violent spasm of the larynx, nearly amounting to suffocation, which came on just as he was about trying to eat a small piece of mutton, and, in the attempt at swallowing it, which the æther draught relieved. From this date his nervous system lost its power, but there were no symptoms of effusion. The turbid and purulent deposits in the urine increased, and the depression also. The tongue now became for the first time brown, although its edges were clean; hiccup came on with great severity, for which I prescribed, (in conjunction with Mr. Beales, of Halesworth, who was now called in by the request of his friends, although I had suggested the propriety of some surgeon meeting me in consultation upon the case some weeks previously,) the nitric acid, with prussic acid and buchu, with a mustard plaster, to the scrobiculis cordis, but with no benefit. Musk, camphor, opium, and assafœtida shared the same fate in relieving it, when I had recourse to chloroform, in six-drop doses, twice a day, which calmed the patient, and stopped the hiccup. Previous to Mr. Beales' coming, I had for a fortnight begged my patient to allow me to introduce a catheter, to aid me in my diagnosis, but he would not submit, and it was passed with the greatest difficulty, although done admirably, by Mr. Beales, when we met, on account of the patient throwing himself about most violently. The instrument appeared to strike against a stone, or roughened surface, which we both found it difficult to diagnose, in consequence of the above-named cause, but the opinion we came to was, that there was severe mischief going on in the bladder, that it was corrugated, the prostate gland enlarged, and I thought disease of kidney. There was so very little albumen when Mr. Beales and myself tested the urine, that if there had been stone, he would have recommenced lithotomy.

The evening of the day of consultaton bloody and fœtid urine was passed, and from this time portions of encephaloid matter were discharged with it, so as to render the room scarcely bearable. I told his friends the formidable nature of the disease, and to be prepared for the result. He was comatose for seven days, and was gradually sinking for four.

Post-mortem examination, seven hours after death.—The amount of disease was very great, both in the kidneys, bladder, and prostate gland. The first were congested, friable, and their pelves were dilated and filled with purulent matter, the right especially, and imbedded in fat, caused by chronic pyelitis. The bladder itself was hypertrophied and corrugated in the posterior superior part. The tongue healthy. The anterior superior wall and upper part of the neck of the bladder was firmly attached to the back of the pubes and pyramidal muscles by a morbid mass of an encephaloid character; and whether this would have gone on to open ulceration through the abdominal parietes, or have passed off by increased fœtid discharge of urine, and thus have exhausted him, I can hardly decide, but I fancy the former. The prostrate gland was schirroid, and about the size of a very large chesnut. I beg to add, that for the last few days the patient passed but little water, and I had a doubt as to the propriety of introducing the catheter; but I refrained, in consequence of there being no apparent distention of bladder. Previously to commencing my *post-mortem* I introduced the catheter, when four ounces of very fœtid urine came away. The liver, stomach, and viscera generally were healthy in appearance; there was abundance of fat also.

Remarks.—The practical remarks I should be inclined to offer on this case would be, to bear in mind first symptoms, such as the extreme pain, before and after passing the least drop of urine, in the course of the urethra, extending along the perineum, and even to the pubes, which was in some measure relieved by pressure upon the glans penis. The ability of the patient to bear exercise in a gig or even on horseback, and with this there was the want of any amount of hæmorrhage, so characteristic of this malady, and which obscured this case. The necessity of introducing the catheter in all obscure cases of urinary disease is of paramount importance, and particularly in one of so formidable a character as this; for although there is no chance of curing this dreadful malady, I fancy the distressing and agonising pain might be assuaged by demulcent and sedative injections, and by the introduction of a gum elastic catheter just sufficient to enter the bladder, thus allowing the escape of the smallest quantity of urine; for the natural or most common situation of these malignant growths is, according to Sir B. Brodie, in his excellent work on diseases of the urinary organs, near the neck of the bladder, which was the case in this instance; and the bladder having become a fixed point, from its attachment to the pubes, as brought to light by the *post mortem*, explains the reason of the forcing efforts, and inability to pass only a few drops at a time, and only when standing up.

I should have remarked that about three weeks before his decease the countenance became yellow or parchment like, and the legs and arms began to waste; and, strange to say, the pulse never failed till within a few hours of death, which was to be accounted for by the heart being sound.

Davenport's bimeconate of opium in solution acted most beautifully in the relief of this poor fellow's sufferings, and without producing headache.

Hospital Reports.

STRATFORD-ON-AVON INFIRMARY.

CASES OF PNEUMONIA IN CHILDREN.

Reported by Mr. BERNARD RICE, St. Bartholomew's Hospital.

In diseases of children, from their being able to give but little information concerning their sufferings, and in cases of affections of the lungs, from an inability to avail ourselves of an important part of auscultation, any additional means tending to facilitate their detection are exceedingly useful, even if they be only occasionally present.

During a recent epidemic of measles, pneumonia having frequently supervened, I have had an opportunity of verifying a former observation, of the occasional presence of an auscultatory sign, which is not alluded to in the most recent English work on the diseases of children, viz., that by Dr. West.

I mean a harsh, dry, respiratory murmur, heard in one or both dorsal regions, which frequently precedes the existence of minute crepitation, and often exists for some considerable time. This sound conveys to my mind, the impression of its being due to a dry state of the membrane lining the air-cells, owing to a congested state of its vessels. In the first case this sound was plainly heard, and by means of proper treatment minute crepitation was not set up, *i.e.*, the congestion was prevented from passing on to inflammation. In many other cases a similar sound has been heard; in some arrested by treatment, in others being succeeded by minute crepitation, as in the third case

At the same time that this is present, other urgent symptoms are found to exist, viz., hurried respiration, a flushed and anxious countenance, a dry tongue, and quick and sharp pulse. It is also easily arrested, a few doses of calomel administered every four hours, and aided by a warm bath, being generally sufficient. This treatment was recommended to me by Dr. Thomson, who had rarely found it fail, and the few cases in which I have used it, bear out this assertion. To him I am also indebted for the care of many of the cases on which these observations are founded.

After the existence of minute crepitation, a sound is frequently heard partaking of a character between rhonchus and bronchial respiration, easily mistaken for the latter, unless carefully listened to. In the second case it was mistaken for bronchial respiration, and treated accordingly. This sound, I think, indicates the presence of a portion of the products of inflammation, escaped from the air-cells, but still lodged in two or three only of the bronchi leading to them.

Case 1.—F., aged 14 months, a healthy child, of bilious temperament, on May 20th, 1851, was first observed to have slight difficulty in breathing, and fever, for which a dose of magnesia was given, and the warm bath used at night.

On the 21st, the difficulty in breathing increased rapidly about the middle of the day. The symptoms when first visited were as follows:—Countenance pale and anxious, with a circumscribed flush on cheeks; alæ nasi dilating during respiration, which is exceedingly hurried; great heat and dryness of skin; a quick (140) and sharp pulse; a dry tongue, with prominent papillæ; bowels open freely (by medicine); great thirst; no appetite. Has vomited a small quantity of yellowish matter. Has a frequent cough in paroxysms.

Auscultation.—In right dorsal, and lower parts of right scapular, and left dorsal regions, a harsh dry respiratory murmur is plainly heard. Ordered—Hydr. Chlor., gr. j.; Pulv. Glycyrrhizæ, gr. ij., quartis horis cum Potass. Nitr., gr. iiss.; Liq. Am. Ac., dr. j., ex Aquâ. Thermæ vespere.

22nd.—Slept tolerably during the night; respiration much less hurried; less heat of skin and perspires freely; pulse 110, soft, and quick; tongue moist and slightly furred; bowels not relieved as yet to day; vomited a little bilious matter this morning; less thirst. Cough less violent. Auscultatory signs present but in a less marked degree. Ordered—Hydr. c. Cretâ, gr. iij.; Rhei Pulv., gr. iv., hac. nocte.—Rept. Haust. c. Vin. Ipecac., m. vij. Thermæ vespere.

23rd. Was restless during the first part of last night, but slept well towards morning. Extreme pallor of face; skin cooler and moist; pulse 98, soft; less thirst; Appetite improving; bowels freely open. Was very faint after the bath. Respiratory murmur natural. Rept. Mist.

She convalesced rapidly from this time, but on the 28th a deposit of lithates appeared in the urine. Relieved speedily by nitre and bicarbonate of potash.

Case 2.—Elizabeth R., aged 4 years and a half, admitted an out-patient April 5th, 1851, a stout healthy girl, of florid complexion. On recovering from measles, being incautiously exposed to a cold wind, an attack of pneumonia supervened. Has had difficulty of breathing for two days.

Present symptoms.—Hurried respiration, nearly 50 in a minute; hot and dry skin; sharp pulse (125); tongue moist and red, with prominent papillæ; bowels freely open; great thirst and loss of appetite. Frequent cough, attended by the occasional expectoration of a tenacious mucus, streaked slightly with blood. Dulness and minute crepitation in both dorsal regions. Ordered the eighth of a grain of tartar emetic every half hour until vomiting supervenes.

6th.—Less hurry of respiration, and less cough; hot and moist skin; pulse 110, sharp; crepitation much less intense. Rept.

7th.—Hurry of respiration and cough decreasing; skin cool; pulse 120, soft; less thirst; appetite improving; a sound, somewhat resembling bronchial respiration, heard in the right dorsal region. Ordered Hydr. Chlor., gr. iss., quartis horis ad vices sex.

9th.—Improved considerably; cough troublesome

occasionally. Ordered Tinct. Camph. Co., m. viij. ex Inf. Cascaril., oz. ss., ter die.

She recovered rapidly, and was discharged April 21st, 1851, quite well.

Case 3.—Joseph T., aged 3 years, became an out-patient May 9, 1851. Has lately had measles and is now suffering from hooping cough; has frequent paroxysms of cough; a weak and quick pulse; moist tongue, and slight aphtha; bowels open; appetite impaired; is much emaciated; minute crepitation heard in the right dorsal region, and in the left a harsh dry respiratory murmur; puerile respiration elsewhere. Ordered Hydrarg. c. Cretâ, gr. iij.; Pulv. Ipecac. Co., gr. ij., hâc nocte.—Vini Ipecac., m. xv; Sp. Ammon. Arom., m. x.; Tinct. Opii, m. ij., ex aquâ quartis horis.—Emp. Lyttæ thoraci.

During the next two days he continued much the same, but on the 12th he had an anxious countenance; hurried respiration; alæ nasi dilating; a quick (120) and sharp pulse, and the whole of the mouth was covered with aphtha; considerable heat of skin; bronchial respiration and bronchophony in the right, minute crepitation in the left, dorsal region. Ordered Hydrarg. Chlorid., gr. j.; Ant. Pot. Tart., gr. 1-12th, omni horâ.—Potass. Chlor., gr. iij.; Syr. Pap. Alb., dr. ss., ex aquâ quartis horis. Thermæ statim.

In the evening, when visited, the symptoms remained as before, the pulse weaker, and he appeared much more exhausted.

13th.—Scarcely any anxiety of countenance; respiration much less frequent; pulse stronger, but still quick; bowels very freely open; minute crepitation in both dorsal regions. Continue mixture.

14th.—Much as yesterday. Rept. Pulv. Cal., &c., ad vices tres.

15th.—Continues improving; much less aphtha. Ordered Emp. Lyttæ sub scap dextr; Potass. Nitrat., gr. iij.; Liq. Ammon. Ac., dr. j., ex Aquâ, quartis horis.

16th.—Yesterday wine was given without leave, the child became much worse, and great debility showed itself; bronchial respiration returned in the right dorsal region. He was ordered Hydrarg. Chlor., gr. ss.; Pulv. Ipecac. Co., gr. j., quartis horis, but gradually sank and died on the morning of the 17th.

No *post-mortem* examination.

Provincial Medical & Surgical Journal.

WEDNESDAY, AUGUST 6, 1851.

As but a few days must necessarily elapse between the publication of the present number of our *Journal*, and the Anniversary Meeting of the Association which we have the honour to represent, we take the opportunity of urging upon our readers, the more than ordinary inducements, which may well serve to lure even the least locomotive of them from the comparative seclusion of every-day occupations. Interesting in many points of view as these annual reunions must be acknowledged to be, by those who, like ourselves, have had the privilege of frequent attendance upon them, accidental circumstances give a fair guarantee that the forthcoming meeting will, both in scientific value, as well as social and professional benefit, greatly surpass those of former years.

The "Great Exhibition" has become a household word in every mouth, and we need not therefore be ashamed to invoke its magic influence, as in itself a powerful reason, why the meeting of 1851 should be pre-eminently successful as far at least as numbers contribute to so desirable an effect. There may be some, though we would fain hope a small minority, who, when called upon to travel a long distance, solely for scientific purposes, would hesitate to leave their *domus atque placens uxor*, but when such take it into consideration, that for little or no extra expense, they may at the same time also enjoy the grand spectacle of the day, and thus combine amusement with profit, they will doubtless feel the temptation to be too strong for their resolution. There are many who are, on the other hand, anxious to witness the wonders of the Crystal Palace, but would scruple to desert their practice solely for amusement; to such it may be said, that a more suitable opportunity can never offer, of fulfilling a laudable wish, while they may at the same time gratify their taste for scientific inquiry, and the interchange of professional courtesies.

The exhibition has, moreover, been the means of bringing to England distinguished foreigners of all denominations, and among them many who are celebrated in our own profession. These we trust will grace the meeting with their presence, and thus give an *èclat* to the Anniversary of 1851, which could scarcely be attained at a less favourable juncture.

In addition, however, to the inducements thus afforded by the great exhibition, to encourage the hope of a large muster of our Associates, something may be expected of the locality of the meeting and its propinquity to the metropolis. Brighton may fairly be termed the queen of watering places, and in a topographical view alone will well repay the attention of visitors from inland and more rural districts.

Its vicinity to London will also justify the reasonable expectation that we shall be honoured with the society of many of the heads of the profession.

The above considerations, we believe, fully entitle us to anticipate a numerous meeting, irrespective of any attractions offered by the contemplated proceedings. These, however, we are enabled to assure our readers will possess no common interest.

Of the position and prospects of the Association itself, it is gratifying to be able to speak in the most satisfactory terms. It retains, unquestioned, the reputation which it has some time possessed, of being one of the most influential medical bodies in the kingdom. It has done much for science, and more for the cultivation of honourable principles, and the discountenance of professional dishonesty and chicanery. In the question now under agitation, as to the treatment of the homœopathic quackery and its abettors, we trust that it will at the ensuing meeting pronounce in unmistakeable language, that there can be no compromise between truth and error. No less will be expected from an Association instituted for the maintenance of the honour of the medical profession, than that it shall, by a deliberate vote, brand with well-merited disgrace, those qualified men, who, by coquetting with, or openly espousing the quackeries of the day, do not hesitate to sacrifice every honourable principle at the shrine of mammon.

Whilst on this subject, we think it advisable to draw attention to the communication from Dr. Cormack, published at page 444. It may be read with advantage by every member of our profession who has its dignity and usefulness at heart. There is so much difficulty in carrying on a discussion on the absurdities of homœopathy with a non-professional person, that we are not surprised that Dr. Cormack should fail to convince his former patient, still we honour the attempt, and must admire the gentlemanly tone in which the correspondence was conducted. It is so trying to the temper to find ourselves before a tribunal entirely ignorant of the merits of the case, that we can scarcely wonder that some irritability should occasionally be evinced. Nevertheless, it should, if possible, be avoided, and we cannot do better, in similar circumstances, than to profit by the example set us by our worthy associate.

Mr. Bottomley, of Croydon, has made arrangements with the Railway officials for the issue of return tickets to members of the Association at the following reduced rate, viz:—

Express Train.		Ordinary Trains.	
First Class	... 22s.	First Class	... 17s. 6d.
Second Class	... 17s.6d.	Second Class	... 14s.

Return tickets not available for the 5 p.m. down train, or the 8.45 a.m. up train.

A late train for London will leave the Brighton Station on Thursday evening, the 14th of August, at a quarter-past ten o'clock, arriving in London at half-past eleven.

The Tickets will be issued at the London Bridge Station on the 12th, 13th, and 14th of August, returnable up to the night of the 15th, to members of the Association only, and must be asked for specially as such.

Reviews.

Memoires sur la Digitaline. Par MM. Homolle et Quevenne. Rapports faits a l'Academie de Medecine. Jan. 1830, et Fev. 1851.

Of these memoirs, two in number, the first is entirely chemical in its contents, the second embraces the physiological and therapeutical action of digitaline—the active principle of the digitalis purpurea. Of the first memoir we shall only remark that it contains full directions for preparing and purifying digitaline, which is described as a resinoid substance of a laminated aspect, and giving an emerald green reaction with concentrated hydrochloric acid.

The second memoir gives an extended historical account of the opinions of practitioners on the properties of digitalis, as well as an analysis of certain physiological and clinical experiments on the properties of digitaline as compared with digitalis.

Of the physiological experiments on the action of digitalis and digitaline on man and animals, it need only be said, that the authors have found that this drug invariably depresses the hearts' action, but not to the extent which is generally admitted; out of six trials, they found the average falling of the pulse to be only four beats; but in one it fell as low as seventeen beats in the minute. They noticed, moreover, that the greatest effect took place, not during the exhibition of the drug, but after its suspension. In reference to the medicinal action of

digitalis and digitaline, the authors state that they have not met with intolerance of the drug in more than 3 per cent., and that this intolerance was due to an emetico-cathartic action, which speedily subsided. They determined also, that as a remedy, digitaline was preferable to the powder of digitalis, inasmuch as the action was more certain, and the dose could be more carefully graduated. The conclusions which they have drawn from their multiplied experience are as follows:—

1. Digitaline possesses all the therapeutical virtues of digitalis.

2. It regulates the action of the heart, and retards the frequency of its movements. These effects are produced by from two to five milligrammes in the twenty-four hours.

3. Beyond this dose, digitaline has an emetico-cathartic action, sometimes suddenly, at others gradually induced.

4. Digitaline has a poisonous effect when given in a large dose. This effect may be induced in the dog by injecting one centigramme into the veins, but when given by the stomach its toxic effect is not to be apprehended, as the excess of the drug is eliminated by vomiting and purging.

5. Digatiline is to be preferred to the powder of digitalis, from the greater facility of exhibition, and its more certain action.

6. The authors have observed the diuretic effect of digitaline, but do not consider this as a constant action.

The above memoirs having been submitted, as is the custom, to a committee of reporters, MM. Rayer, Soubeiran, and Bouillaud, who were selected for the purpose, communicated to the Academy the results of their own investigations. They for the most part accord with those of the authors of the memoirs, both as to the superiority of digitaline over the other preparations of digitalis, and also in regard to its physiological and medicinal action. They found it extremely serviceable in heart diseases accompanied by irregularity of rythm; not only reducing the frequency of the pulse, but restoring its regularity; at the same time, however, they find that the force of the beat is diminished, for which reason, they consider that some discrimination is required in the selection of cases for its exhibition.

Proceedings of Societies.

SHROPSHIRE BRANCH.

The anniversary meeting of the Shropshire Branch of the Provincial Medical and Surgical Association, under the Presidency of Richard Thursfield, Esq., of Broseley, was held at Hay Gate, on Tuesday, the 15th of July. A considerable portion of the members assembled at two o'clock, for the transaction of business and the discussion of professional subjects. There were present,—

R. Thursfield, Esq., Broseley; Matthew Webb, Esq., Wellington; F. Webb, Esq., Wellington; R. W. Maxon, Esq., Wellington; J. Ryder, Esq., Wellington; W. Rowlet, Esq., Wellington; Dr. Drury, Shrewsbury; J. Y. Arrowsmith, Esq., Shrewsbury; W. Clement, Esq., Shrewsbury; J. Dicken, Esq., Shrewsbury; J. Nigel Heathcote, Esq., Shrewsbury; Samuel Wood, Esq., Shrewsbury; — Whitwell, Esq., Shrewsbury; P. Cartwright, Esq., Oswestry; Henry Bidwell, Esq., M.D., Albrighton; Robert Broughton, Esq., Ruyton; J. B. Hickman, Esq., Brocton; J. R. Humphreys, Esq., Shrewsbury.

The business of the meeting was opened by the President, who, in expressing his gratification at the attendance of so many members, hoped that an additional impulse would that day be given to the success and prosperity of the institution. He enlarged on the importance of meetings like the present, and the beneficial results of a number of medical men congregating together, and conferring on the different modes of treatment of diseases. He dwelt on the collective information so to be obtained, and on the reciprocal advantages derivable therefrom. He particularly inculcated union and goodfellowship amongst those who had to undergo so many trials in an arduous and ill requited profession, and above all, he trusted their annual meetings would always have the effect of making them much better known to each other and of exciting them to cultivate those Christian feelings which should especially prevail amongst the members of an honourable profession, and which would tend to preserve and perpetuate a good understanding with each other, and lead to acts of benevolence and charity to their afflicted and suffering brethren, a cause which he was afraid from all he heard, had need of good assistance at the present time.

The President then stated that he had to regret the unavoidable absence of Dr. Henry Johnson, Dr. Banning, and Dr. Oliver, and he had also hoped at one time to have had the attendance of Drs. Evans and Bell Fletcher of Birmingham, but they were also prevented. He had letters of apology, for non-attendance from Mr. Brookes, Mr. Pidduck, Mr. Wilding, and others, who were generally very constant attendants. He had also letters from some thirty other gentlemen, who were unable to respond satisfactorily to his invitations.

The President was listened to with great attention throughout his discourse, and on its conclusion, he

introduced to the meeting a patient suffering under one of the most formidable maladies that human nature is liable to,—viz., osteosarcoma; the subject of which was severally examined by all the gentlemen present, and amongst all excited one universal feeling of sympathy and commiseration.

The subject of the resignation of the secretaryship by Dr. Drury, next claimed attention, and such was the universally high estimation in which that gentleman's services were held, that all the members joined in soliciting him to continue to discharge the duties of Secretary. An arrangement was at length happily effected by the kind consent of Mr. Humphreys, House-surgeon to the Salop Infirmary, to be associated with Dr. Drury as conjoint Secretary, thereby dividing the labours of the office with that gentleman. Dr. Drury and Mr. Humphreys were then formally appointed Secretaries. Two Presidents were also appointed for the next meeting, an arrangement necessary in consequence of the very distant residence of one of the gentlemen.

J. B. Hickman, Esq., Brockton, and R. Broughton, Esq., Kington, were unanimously appointed Presidents-elect.

The Central Council, at Worcester, having requested the opinion of this Branch on the recent important concessions made by the Royal College of Surgeons of England, it was proposed by P. Cartwright, Esq., and seconded by Mathew Webb, Esq.,—

"That a copy of the memorial recently forwarded to Sir George Grey, Bart., by this Branch of the Association, be sent to the Central Council, at Worcester, with a request that at the meeting at Brighton they would take such steps as may be considered advisable, to urge upon Sir George Grey to grant the proposed new Charters to the Royal Colleges of Physicians and Surgeons, and introduce the long-expected Bill for the better regulation and improvement of the profession."

This resolution was agreed to unanimously.

The subject of the Benevolent Fund next gave rise to a very long and animated debate, in which the President, Dr. Drury, Mr. Cartwright, and Mr. Hickman took a very active share.

This discussion we must condense, and give the general bearings of it.

It was pointed out that there are three institutions at present in the profession adapted to the relief of its suffering members:—

1st. The British Medical Fund; a provident Insurance Society.

2nd. Mr. Propert's proposed Benevolent College; an Asylum for the distressed, and a Collegiate Institution for orphans.

3rd. The Benevolent Fund connected with the Parent Association.

The first, the British Medical Fund, as a provident and relief society for medical men, their widows and orphans, was favourably commented upon as a desirable insurance office well worthy the support of the profession; its benefits were, of course, restricted to its members, and if supported would in time become a valuable institution. To use the words of its originator,—"It is an institution that tells medical men in their prosperity to lay by a little, that when prosperous no longer they *may not want*."

The second, the noble scheme of Mr. Propert, recently brought forward with great promise of success at a meeting held in London, over which Earl Manvers presided, and which proposes the formation of an asylum for the destitute, and a collegiate education for their sons, received the flattering approval of several speakers.

But the general bias was obviously in favour of the *Benevolent Fund*, that invaluable charity "whose gifts come as so many holy blessings," and whose benefits, diffusive and large, have been doled out liberally, far and wide, for the last sixteen years. As the *only purely charitable medical fund* in England, it deserved the strenuous support of the profession at large, but being especially connected with the Provincial Medical and Surgical Association, it had peculiar claims on all who were members of the Association, and it well merited to obtain a much more generous support amongst the medical practitioners of Shropshire than had hitherto been accorded to it. If a case of distress was but rarely met with amongst the Salopian members, the words of their truly Christian and philanthropic brother, Mr. Newnham, of Farnham, should never be forgotten:—"The supplication of the widow,—the piteous lament of the orphan,—the cry for help of the destitute—of the naked—and of the starving, may not in some places break in upon the ear, and awaken the sympathies of home and kindred. But the great *fact* of irremediable distress was not *less a fact*; and to succour those who are ready to perish is not *less a duty* because we do not see and hear them."

It had been graphically and touchingly observed at a late meeting relative to distressed members of the profession, that "they do not retire from practice, they do not die, but they *disappear*." "Poverty spreads her dark mantle over their path, and they are *seen no more*; they cannot dig—to beg they are ashamed." The Benevolent Fund can alone lend them aid—may it never want support.

The attention of the members was particularly directed to the letters of Mr. Newnham and others, which have recently appeared in the Society's journal; and in order to bring matters to a practical bearing, it was suggested that a local Committee should be appointed to promote the success of the Benevolent Fund throughout the Branch, to carry out which suggestion Mr. Arrowsmith proposed, and Mr. Clement seconded, the following resolution:—

"That this meeting, highly approving of the Benevolent Fund connected with the Parent Association, recommend that a Committee, (with power to add to their number) be appointed, to promote its objects throughout the Shropshire district, and that Mr. Cartwright, Mr. Hickman, Dr. Drury, Dr. Johnson, Mr. Dicken, Mr. Webb, Mr. Thursfield, and Mr. Wood, be requested to act on such Committee."

The resolution was agreed to with much approbation, and the names of Mr. Arrowsmith and Mr. Clement (on the suggestion of Mr. Cartwright) were added to the Committee.

Some new members were next enrolled, when dinner being announced, about thirty gentlemen, including

members and visitors, sat down to a most sumptuous repast.

After the health of the Queen and other loyal toasts, the PRESIDENT, with great good taste and emphasis passed a high eulogium on Sir Charles Hastings, the Founder of the Provincial Medical and Surgical Association, and the applause with which the toast was received evinced how sincerely the talents and virtues of their excellent Founder and President of the Council are appreciated by his "friends round the 'Wrekin.'"

The health of Mr. Thursfield, the President of the meeting, was drank with enthusiasm, and many compliments bestowed on him for the energy he had that day displayed in bringing together so good a meeting.

The healths of those who were unavoidably absent, particularly Dr. Henry Johnson, and also the Vice-President Mr. Hickman, were drank in succession; also the health of their talented associate, Mr. Clement, who, in responding to the toast proposed with much good feeling, and in a very flattering manner, the medical and surgical officers of that most valuable institution, the Salop Infirmary, the successful practice of which, he stated, in its medical and surgical departments, was not surpassed by that of any other similar institution in England.

Dr. Drury, Mr. Dicken, and Mr. Arrowsmith, severally returned thanks for the compliments paid them as officers of that most invaluable institution, and expressed their deep anxiety to render it not only as valuable as possible to the patients who reaped the benefit of admission within its walls, but also to afford on suitable occasions opportunities to their professional brethren of witnessing any cases of more than usual interest.

The PRESIDENT next proposed the "Presidents-elect, Mr. Hickman and Mr. Broughton," and hoped they would have a good meeting next year, "in that sweetest of vales" the Vale of Llangollen.

The health of "Mr. Webb, the senior member, and the surgeons of Wellington," the "Visitors who had honoured them that evening," and many other toasts, concluding with "All friends round the Wrekin."

The Company dispersed by the last train, highly gratified.

BIRMINGHAM PATHOLOGICAL SOCIETY.

JANUARY 2ND, 1851.

MR. RUSSELL IN THE CHAIR.

Four Cases of Ovariotomy, with the Preparations in illustration of them. Two of the cases perfectly successful.—By Dr. ELKINGTON.

I.—A FINE specimen of fibrous tumour, the size of a large cocoa-nut, which had been developed in the folds of the peritoneum, and was accompanied by ascites. The following is a brief sketch of the history of the case:—

Mary Boyce, aged 37, mother of two children, became an out-patient of the Lying-in Hospital September 10th, 1845. In 1843 she discovered a tumour, the size of a large hen's egg, in the right iliac region. The swelling gradually increased, and at the time of her application she was nearly as large as a pregnant woman at her full period.

December 11th.—She measures from the scrobiculus cordis to the pubes twenty-eight inches; from the umbilicus to the pubes fifteen inches; around the body at the epigastrium thirty-four inches; around the body at the umbilicus fifty-three inches; and midway between the umbilicus and pubes fifty-four inches; fluctuation is very distinct; dulness on percussion over the whole lower part of the abdomen; on pressing the fingers suddenly upon the right side, the ends strike against a solid mass; her health is good, but she suffers much inconvenience from the swelling and distension; the uterus is healthy, and *can be moved freely in every direction* with the uterine sound; there is prolapsus of the posterior wall of the vagina. About the end of December she became so much distressed by the increased size of the swelling, that it was considered necessary to tap her. Thirty quarts of ascitic fluid were drawn off. After the operation the solid tumour was found to be *very moveable, and apparently free from adhesions.* It was supposed to be a fibrous tumour of the ovary. She rapidly increased in size again, and was obliged, in about six weeks, to be tapped a second time. This afforded her relief only for a short time, and she was obliged to have recourse to the operation nearly every month. At length she suffered so much, and became so very urgent to have the tumour removed, that it was decided in consultation with two or three medical friends, to make the attempt.

The operation was performed in July, 1846, in the presence of Mr. Southam, of Manchester, Dr. Bell Fletcher, and many other friends. An exploratory incision was first made, the fluid evacuated, and as there appeared on introducing the finger to be no adhesions in the immediate neighbourhood of the incision, it was enlarged to the extent of five or six inches, so as fully to expose the tumour and its attachments. It was then found that it had contracted adhesions at the lower part of the fundus of the bladder, to the fore-part of the fundus of the uterus, and to the parietes of the abdomen immediately above the pubes, also above and behind to the intestines. These adhesions were considered of such a serious a character as to preclude the possibility of completing the operation, consequently the wound was carefully closed, and the patient put into bed. She died on the fourth day, of peritonitis.

This case illustrates the difficulty of diagnosis as to the presence of adhesions. It has been stated that the tumour was very moveable in all directions, and that the uterus was also readily moved from side to side with the uterine sound. This is readily explained. The adhesions were very long and loose, so as not to confine or interfere with the motions of the tumour or of the uterus.

II.—A cast of a large ovarian tumour of the multilocular kind, removed by operation. The tumour weighed fifteen pounds.

The patient, Mrs. L., consulted me October 6th, 1847. She stated she was 46 years of age, had been married twenty-five years, and had had five children. In 1830 she first perceived a tumour in the right iliac

region; it remained stationary nearly five years. She had two children after its first appearance. In 1838 she had a severe illness, which continued some months. On recovering from this illness the tumour was much diminished in size, and remained so for six years; it then began to increase, and during the last two years has grown rapidly. On making an examination I found the tumour occupying the lower half of the abdomen, and extending a little above the umbilicus, which was bulging out. The tumour appeared to be divided into two portions. There is fluctuation in the tumour, but it is felt more distinctly in some parts than in others. The swelling extended from the crista of one ilium to the crista of the other, resting against the pubes, and pressing upon the bladder. Percussion dull over the whole surface of the tumour, eliciting a clear sound in the lumbar regions. The integuments were tight, and not moveable over the tumour.

Examination per Vaginam.—The uterus was situated high up, the os pushed forwards, no enlargement of the uterus. The sound passed to the extent of two inches and a quarter only. The uterus moveable in every direction, but not freely so. Owing to the tumour being situated so low down and pressing against the pubes, the fundus uteri cannot be traced externally.

Diagnosis.—Ovarian multilocular tumour of the right side, probably adherent to the parietes. The uterus healthy but its cavity shortened by the pressure of the tumour.

I saw her again in February, 1848. She was much larger, and constantly suffering from pain and sickness, which continued to harass her till the beginning of May. She was then relieved from these distressing symptoms, but suffered so much from the increase of size, and from the difficulty of breathing, that she begged earnestly to have the tumour removed. I explained to her that it was an unfavourable case for an operation, and that we should probably find adhesions which would not only increase the difficulties of the operation, but materially lessen the chances of success. She declared that she would willingly incur the risk, and so anxiously entreated us to operate, that I consented on condition that Dr. Clay of Manchester, who was about to visit Birmingham, would give me the benefit of his great experience in such cases, and should approve of the measure. Dr. C. thought there were adhesions, but that it was a case in which we should be quite justified in operating. The operation was performed July 18th, 1848, in the presence of Dr. Clay, Dr. B. Fletcher, Dr. Mackay, and several other medical friends. The tumour was connected by extensive adhesions to the parietes at the fore and lower part of the abdomen, and to the edge of the omentum, which was spread out on the upper edge of the tumour. It was very vascular, and supplied by several vessels, which passed from the lower edge of the omentum to the surface of the tumour. Several vessels were secured. Upon the anterior surface of the tumour there was a deep groove passing directly across its centre, which caused the appearance of two tumours. The patient died 36 hours after the operation, apparently from the shock.

III.—A large ovarian multilocular tumour, which weighed at the time of its removal nearly forty-five pounds. The following is a short history of the case:—

Mrs. Moore, Walsall, consulted me June, 1848. She says she is 31 years of age, a dress-maker, married 15 months. She began to menstruate at 17, continued regular and in good health till about two months before she was married. She was then "unwell" every week or two, and had a copious discharge. A few weeks before her marriage she had frequently slight pain in the right side. About three months after marriage she began to increase in size, and after another month the swelling increased rapidly. The swelling first appeared on the left side. She was supposed to be pregnant. She lies down on the left side. Has prolapsus uteri. Is as large as if she were in the last month of pregnancy. The tumour is very moveable, irregular, and nodulated. There is indistinct fluctuation, varying in its character at different points.

Examination per Vaginam.—After replacing the uterus, which was prolapsed, there could be felt no enlargement of that organ; the uterine sound showed that the length of the cavity was natural, and that the uterus was moveable in every direction. She menstruates regularly. No enlargement of the breasts. With the stethoscope no bruit to be heard in any part of the tumour.

Diagnosis.—Disease of the left ovary of the multilocular form.

She continued to increase in size. In Jaunuary, 1849, she measured 45 inches round her; at this time she began to suffer very much from the great size and dragging of the tumour. Her breathing too, was much embarrassed.

She was tapped on the 28th of February; a quart of thick gelatinous fluid was drawn off, slowly, and with difficulty; it then ceased. A second cyst was tapped, and altogether about five gallons of fluid drawn off, but the size of the tumour did not appear to be reduced more than one half. In a month she was as large as ever. She now became very anxious to have the tumour removed, and as it seemed to be a favourable case for extirpation, and as there appeared no chance of tapping affording more than very partial and temporary relief, it was decided that we should have recourse to ovariotomy. The operation was performed on April 3rd, in the presence of Dr. Clay, of Manchester; Mr. Fletcher, Walsall; Mr. Dehane, Wolverhampton; and several other medical friends. The tumour was so very large that, although the incision was extended to ten or twelve inches, we were obliged to empty one or two of the cysts before we could remove the tumour. Fortunately there were no adhesions of importance. The pedicle was broad, and was tied by a double ligature. The operation occupied about twenty minutes. She scarcely had a bad symptom after, recovered rapidly, and was out of doors in a month. The first ligature came away on the eighteenth and the second on the twenty-first day. Her recovery was perfect, and she has continued quite well.

In April last (*i. e.* 1851) she was confined of a fine healthy girl; had an easy labour, and a rapid recovery.

IV.—The next was a beautiful specimen of a fibrous tumour of the left ovary, weighing twelve pounds,

removed by Mr. Day, of Walsall, from whose report the following short sketch has been taken:—

Mrs. Howard, aged 42, married twenty-one years, has had nine children. About two years and a half since she found an enlargement in the left hypochondrium, which gave her no uneasiness. She consulted Mr. Day about six months afterwards, who found a hard tumour the size of a cream jug, readily moveable in every direction, and attached, as he imagined, by a thin pedicle to the left ovary. She afterwards became pregnant, and had a favourable labour. After delivery Mr. Day made an examination, and found that the tumour was double the size it was before pregnancy, but still moveable in every direction, and apparently quite free from uterine adhesion. She suckled her child twelve months. She gradually increased in size. In June, 1850, her health began to suffer, and she was obliged to wean the child. The swelling increased to such an extent that it became necessary to tap her on August 30th, when three gallons of fluid were drawn off. She refilled rapidly, and in one month was larger than before the operation. At this time Mr. Day says, "Her situation was truly deplorable, being unable to remain in either the upright or recumbent position without excruciating misery, from dyspnœa and severe pain in the region of the liver and heart. But a very small quantity of urine was passed in the twenty-four hours. Diarrhœa was a distressing and constant symptom. She expressed herself suffering intolerable agony, and prayed for the operation to be performed, stating that otherwise she felt sure she must speedily die. Mr. Day operated September 26, 1850. He first drew off five gallons of ascitic fluid with the trocar; then passed a director through the opening made by the trocar, and laid open the abdominal cavity to the extent of five inches, and having ascertained that the tumour was free from adhesions, he continued the incision upwards, making use of his fingers instead of a director, to within a short distance of the ensiform cartilage. He also extended the incision below nearly to the pubes. The tumour being then completely brought into view, was found to be attached by a broad but thin pedicle, about three inches in width, to the left broad ligament of the uterus. The pedicle was secured by a double ligature, and divided close to the tumour. The operation was concluded and the patient in bed in fifteen minutes. The first ligature came away on the twelfth and the second was removed on the fifteenth day. It was followed by a small quantity of discharge, which had the appearance and smell of feculent matter, but the discharge soon ceased. Her recovery was slow and for some time doubtful. She suffered much from diarrhœa, sickness, and an aphthous condition of the mouth and fauces. She was able to walk in the garden on the 31st of October, and from that time gradually recovered her health and strength.

Three other preparations were exhibited; one, a cystic tumour, situated in the anterior wall of the vagina; another, showing a simple cystic tumour growing by a long pedicle from the under edge of the fallopian tube, near to its fimbriated extremity. The third, a cystic tumour of the left ovary, containing a large mass of hair and fatty matter, or adipocere. There is also developed in its parietes one of those cross bands, composed of a dense fibrous substance, which usually marks the locality of the development of teeth. In this instance there is one of those anomalous formations.

Foreign Department.

FRANCE.

An Ovary Removed by Mistake for a Labial Cyst.

At one of the late meetings of the Surgical Society of Paris, M. Guersant, chief surgeon to the Hospital for Children, brought forward a case in which an error in diagnosis was committed, and which ended fatally. The patient was a little girl, eleven years of age, who, ever since she was one year old, had in the left labium a small painless tumour. Of late, however, this tumour had become troublesome, and interfered with walking. When examined, it was found of the size of a small walnut, situated in the thickness of the labium, and extremely moveable, so much so that it could be pushed downwards to the most posterior portion of the labium, and upwards as far as the external ring. It was, however, impossible to press the tumour into the ring, which latter presented no abnormal dilatation. The tumour had a great deal of analogy with a testicle. M. Guersant looked upon it as a cyst, and resolved to remove it. A longitudinal incision brought into view a membrane much resembling tunica vaginalis, and having the aspect of the peritoneum. Through this membrane an ovoid body was observed, which was no other than the ovary; it was attached to a pedicle formed by the fallopian tube, which ran into the abdomen through the inguinal canal. M. Guersant placed a ligature on the pedicle, and cut out the ovary. Acute peritonitis occurred the very next day, and the patient died on the third day after the operation. M. Morel mentioned during the discussion that he had had an opportunity of seeing a tumour of the same kind in the labium, and formed by the ovary; no modification of size or sensibility was noticed to occur at the menstrual period. M. Lenoir stated that Pott has related a case in which the two ovaries were removed by an error in circumstances analogous to those of M. Guersant's patient.

GERMANY.

Structure of the Uterus in Animals.

M. Kilian (*Zeitschrift für Rationelle Medizin*) has published a memoir on the structure of the uterus in animals, both in the unimpregnated and the impregnated state. One remarkable fact elicited by his microscopical researches is, that the adult uterus does not differ sensibly in structure from that of the young animal. It is only during gestation that it arrives at its complete development. The rule does not, however, hold good in respect of the mucous lining, which is more

developed in the full grown than in the young animal. This membrane in the adult is of considerable thickness, and is constituted of utricular glands, covered, according to the author, with epithelium, while the os and cervix are also furnished with vibratile cells.

The increase in the size of the gravid uterus depends on the increase and multiplication of its elements. It is composed of gelatinous-looking nucleated fibres, which increase in dimensions during the progress of gestation. At the close of this process the nuclei also become converted into a fibrous filament.

Below the external muscular layer is a tissue of amorphous cellular formation, mingled with muscular fibres. Lower still we find a layer of cellular tissue which unites the external and middle muscular layers. This tissue treated with acetic acid exhibits the characters of elastic tissue. The second muscular layer is united by the muscular tissue to the decidua.

At the close of gestation the decidua is characterised by the production of a multitude of fat globules, deposited in its cells. The formation of a new mucous lining prior to the destruction of the decidua has not been confirmed by the author. The author has not been able to discover anything resembling nerve either in the empty or the gravid uterus.

The author has carefully studied the interesting question of the *rationale* of the restoration of the uterus to the unimpregnated state, and has ascertained that it is not by the simple return of the developed elements to their original state, but by the formation of new elements in lieu of the old, which become disintegrated and removed, so that, as he observes, a new uterus is actually formed after each gestation. He insists particularly on the formation of fat globules as indicative in the uterus, as elsewhere, of degeneration.

On Fatty Cysts of the Ovaries.

It is not uncommon to find hair, teeth, or fragments of bones in ovarian cysts, which have been regarded as evidences of extra-uterine pregnancy, but according to M. Steinlein (*ib.*) this interpretation cannot be received, as he has found them in persons who were far from the age of puberty. The researches of this anatomist are calculated to throw considerable light on the production of these substances. He has ascertained that the cyst in these cases is composed of several layers, an external one formed of loose cellular tissue, another subjacent, in which the fibres are more closely interlaced, a third of elastic tissue, and a fourth consisting of epithelium. This epithelium covers the entire internal surface of the sac, and offers numerous isolated patches, having a shining appearance. At these shining spots the epithelial cells are round and regular, which is not the case in the other parts of the membrane. Very often small projections like warts are observed, which if deprived of their epidermis are seen to resemble the papillæ of the skin. This resemblance is more evident still under the microscope.

All the portions of the sac which are covered with the dull epithelium are of the same structure. It is these spots which are observed to be covered with hair, springing from pilous follicles, as in the external skin; and, moreover, both sebaceous and sudoriparous glands are also observed. This analogy between the structure of ovarian cysts and skin renders it intelligible that the fatty contents of the former are the product of a sebaceous secretion, and not the result of a conversion of tissue.

The author explains the presence of teeth in ovarian cysts on the same grounds; teeth being, he observes, only a development of cutaneous tissue, and not necessarily confined to the jaws. He admits the difficulty of accounting for the presence of bones.

General Retrospect.

PRACTICAL MEDICINE AND PATHOLOGY.

On Internal Strangulation of the Intestines.—By Mr. Robinson.

Having gone through the various complications of hernia, in a communication which we noticed in a former number, the author continues his valuable essay by an inquiry into the causes, diagnosis, and treatment of internal strangulation of the intestines. A *resumé* of his observations is contained in the following conclusions:—

1. Internal strangulation most frequently occurs in the ileum.

2. Membranous bands are the most frequent cause of internal strangulation.

3. Partial peritonitis is more likely to induce obstruction than general.

4. All the convolutions of the bowels may be matted together by adhesion, without obstruction.

5. Mechanical are not the sole causes of obstruction, as there is reason to believe that the mechanical cause must have been in existence some time prior to the occurrence of the symptoms; other causes must arise to produce them, and the most frequent are sudden exercise, and errors of diet.

6. It is possible for spontaneous cure to take place by ulceration of an obstructing band.

7. The symptoms vary considerably in different cases.

8. The order in which the symptoms arise is important in diagnosis.

9. There are no symptoms by which one obstructing cause can be distinguished from another.

10. The strength of the patient must be maintained, as part of the treatment.

11. Bleeding requires great caution.

12. The operation (of gastrotomy) is only justifiable as a forlorn hope.

13. Metallic mercury has proved useful chiefly in obstruction from ligamentous bands.—*London Journal of Medicine*, July.

Epilepsy treated by Tracheotomy.—By Mr. Cane.

In his various lectures and communications on spasmodic diseases, Dr. Marshall Hall has repeatedly

expressed his opinion that closure of the glottis is a necessary element in the act of convulsion, and has suggested that if an opening were made in the trachea, the convulsion would cease. The justice of the surmise is admirably shown in the following case:—

Mr. Cane was summoned on February 1st, 1851, to the case of a boatman, aged 24, who had become subject to violent fits of epilepsy, one of which had just occurred in so extreme a form as to leave him in a state of deep apoplectic coma and asphyxia, inspiration being performed only "by seldom and short catches, whilst the veins of the head and neck were everywhere visible, and greatly distended." This state had continued nineteen hours. "Feeling convinced," Mr. Cane observes, "that the patient must shortly expire, and that the root of the evil was in the closure of the larynx, I at once proceeded to open the trachea, a matter of no small difficulty, on account of the twisted state of the neck, the engorged state of the vessels, and the constant action of the muscles. The operation of tracheotomy was performed, and the tracheal tube is kept in the trachea to the present time. The relief to the patient was immediate; the air passed into the lungs, the state of spasm subsided, with the turgid condition of the head and neck, and the patient soon recovered his sensibility. This was not the only gratifying result; although the poor man had experienced his epileptic seizures in increasing violence during seven or eight years, and recently thrice a week, he had, on April 1st, during two months, had no return of them. More recent accounts of the patient, who is now in Staffordshire, confirm the former report; the tube is still kept in the trachea, and the epileptic seizures have not recurred.—*Lancet*, July 12.

On Hysterical Affections of the Hip-joint.—By Mr. Coulson.

Mr. Coulson gives the following diagnostic signs of nervous, as contradistinguished from organic, disease of the hip-joint:—

In the nervous affection pain is felt from the commencement in the hip, and extends to the loins and down the thigh. There is great nervous excitability and extreme sensitiveness in the part; and the patient from the first, is unable to walk. Combined with this extreme suffering, the trochanter major retains its proper bearing to the spine of the ilium. There is not the characteristic wasting of the glutæi muscles, and consequently no flattened appearance of the nates. Pressure in these situations, when the bone approaches the surface does not excite greater pain than elsewhere. There are no involuntary startings during sleep. On the contrary, the patient sleeps calmly through the night. In true hip disease the reverse is the case, the sleep, if unaided by opium, is broken by sudden shooting pains and frightful dreams, or vague anticipations of coming pain.

Of the pathology of the disease Mr. Coulson admits that little is known. The joint is healthy in structure. He asks whether the spine is not in a morbidly excited state, and responds truly, or whether the brain is not itself perverted as to its functions, and the pain is not a delusion? His own opinion inclines the other way, and he looks to the sensorium as the organ chiefly affected.

With regard to the treatment, he remarks, that if it be mistaken for organic disease, the line of practice adopted on that supposition will be positively injurious. The patient must be persuaded to leave her couch, and to take air. The diet must be plain and nutritious. Among medicines, he prefers the vegetable tonics and antisposmodics—as valerian. Copland has found most benefit from turpentine internally by enema, but he also associates various tonics and local sedatives.—*London Journal of Medicine*, July, 1851

SURGERY.

Case of Obturator Hernia successfully Operated upon.—By Mr. Obre.

In a communication to the Medico-Chirurgical Society the author, after commenting on the extreme rarity of this form of hernia, and stating that he had been unable to find any record of its having been detected and relieved by operation during life, relates a case in which he operated successfully. The patient, a female, aged 55, the mother of a large family, was seized with symptoms which led her medical attendant (Mr. Gardener) to believe that she was suffering from rupture. She denied that this was the case, and a careful examination convinced Mr. Gardener that there was no hernia in the usual situations of that disorder. A little below the femoral region on the right side, however, he detected a degree of hardness resembling a small gland, and deeply seated, with some general fulness about the part. The author saw this patient on the fourth day after the symptoms had begun; at this time she was suffering extreme abdominal pain in the umbilical region. During the previous twelve hours her vomiting had been stercoraceous and incessant; the countenance pale and contracted; voice faltering; pulse weak, small, and intermitting—in short, all the symptoms of pending dissolution from strangulated intestine were present. On careful examination nothing could be detected but a slight degree of fulness in Scarpa's triangle on the right side, that on the opposite side being well marked. On using firm pressure with the ends of the fingers over the neighbourhood of the femoral artery, and a little below the saphenous opening, a distinct hardness was to be felt, slight in extent, but giving the impression as if the sheath of the vessels was being pressed on. The state of the patient was such as to induce the author to propose to make an incision in the upper part of the thigh, down to the hard structure, in the hope that he might find confined intestine low in the femoral canal. He made a straight incision into Scarpa's triangle, as in the operation for tying the common femoral artery, beginning about three inches below Poupart's ligament. When the cribriform fascia was opened, and the saphenous opening exposed, no hernial sac was found, but the hardened structure could be felt lying deep to the inside of this

opening. The dissection was with some difficulty continued downwards, the fascia lata was divided, and the pectinæus muscle exposed. The fibres of this muscle were divided transversely for about an inch and a half or two inches, and a hernial sac was exposed, which rose up into the wound to the size of a pigeon's egg. The finger being passed along the sac, entered the obturator opening. The sac was opened, and the intestine was found to be a portion of the small gut, blue and congested. The opening through which it passed did not tightly enclose its neck, but it was considered prudent slightly to divide the edge; in doing this the saphena vein was wounded, and it was necessary to apply a ligature to its upper part. This was the only ligature required. After the operation no medicine was given. In the course of the day the bowels acted three times, and in the course of a few days the patient had quite recovered.—Reported in *Lancet* July 5.

MIDWIFERY AND DISEASES OF CHILDREN.

Induction of Premature Labour by means of the Tepid Douche.

In his report of the Vienna Lying-in Hospital, Dr. Arneth narrates six cases in which the above plan was tried, and with perfect success in all but one. The mode in which it is applied is as follows:—A basin of tepid water is placed at a height of twelve feet from the floor. From this a tube is conducted, one half of which is flexible the other rigid. This is introduced into the vagina in a sitting posture, so that the current of fluid is projected against the os uteri. This is to be repeated twice a day. Thirteen douches are about the average required, but in one patient the second induced labour.—*Ibid.*

Diagnosis between Infantile Remittent Fever and Hydrocephalus.—By Mr. Taylor.

It is often an anxious point in infantile pathology to determine whether the cerebral symptoms which may be present in a given case are indicative simply of sympathetic disturbance of the sensorium, or of the series of anatomical changes which characterize the disease known as hydrocephalus. In deciding the question some assistance will be derived from the following summary of the distinctive symptoms in each:—

Remittent Fever.	*Hydrocephalus.*
Head, slight pain in.	Head, violent pain in; tossing of; drawn backwards, and bored in pillow.
Delirium at night frequent; convulsion rare—sometimes at onset.	Delirium seldom; convulsion not early—more towards end of disease; aversion to light and noise.
Easily aroused.	Roused with difficulty; stertorous breathing; squinting; paralysis in late stage.
Cry fretful, if any.	Cry peculiar, sharp and shrill; frequent sighing.
Hands usually thrown about bed (Coley).	Hands tossed towards head.
Countenance heavy and dull; vacant expression, as of fever in adult.	Countenance sometimes anxious, sometimes dull.
Neither knitting of brows, nor pupil of eye affected.	Knitting of brows; wakefulness; pupil of eye contracted in early stage,—sometimes oscillatory, afterwards dilated.
Senses of sight and hearing often dull.	Senses of sight and hearing often acute in early stage.
Pulse quick throughout the disease.	Pulse quick, but irregular in its action and force in early stage; often beating of carotids, and pulsation and prominence of fontanelle; pulse afterwards becomes slow, but, on raising the child, again quickened.
Bowels occasionally constipated at first; frequently relaxed.	Bowels constipated, and very difficult to move.
Motions various; often clayey and deficient in bile; very offensive.	Motions peculiar and characteristic—dark-green, and slimy, like chopped spinach.
Vomiting occasionally at first, but never continuous.	Vomiting early in first stage; often very constant, especially on assuming the erect posture or sitting up.
Pain often in iliac regions, particularly the right.	Pain occasionally at hypochondrium.
Abdomen in advanced stage sometimes tumid.	Abdomen drawn in in advanced stage.
Appetite mostly destroyed; will not take anything.	Appetite sometimes good; will take food.
Thirst often great from commencement.	Thirst not great in first stage; often in latter stage great avidity for constant drink.
Tongue often loaded with yellowish-white fur, in gastric form, and elongated and injected papillæ, giving it a "strawberry appearance;" red, dry, and occasionally brown, in malarial form.	Tongue white; nothing indicative.
Skin very hot; abdomen hotter than the head; picking of the nostrils, corners of the mouth, &c.	Skin not so hot, afterwards cold; head the hottest part.
Paroxysms regular; exacerbations towards night, remissions in the morning.	Varies in intensity, without regularity.
Seldom occurs under three years.	Frequent under the third year; less so after the fifth. More frequent in boys of a scrofulous habit.

—*Medical Gazette*, July 11th, 1851.

TOXICOLOGY.

Accidental Poisoning by Tincture of Aconite.—By Dr. Topham.

Dr. Topham was called to a female suffering under anæmic dyspepsia with leucorrhœa, and who had been

prescribed citrate of iron and quinine. By some error half an ounce of tincture of aconite was added to the eight-ounce mixture. At eleven, A.M., she took one tablespoonful, and immediately complained of numbness in the tongue, with difficulty of swallowing. Soon after she began to cry violently with twitching of the facial muscles. Next she lost the power of walking and began to eject mucus from the stomach. When seen she was lying with the eyelids closed and the pupils contracted. She was quite unconscious but occasionally uttered a plaintive cry. The pulse was weak but regular, the hands and feet were cold. There was constant lachrymation. She was given the sesquicarbonate of ammonia and brandy, under which she rallied.—*Lancet*, July 19.

Correspondence.

OUR RELATIONS WITH HOMŒOPATHY.

To the Editor of the Provincial Medical and Surgical Journal.

Putney, July 29, 1851.

SIR,—While, with you, I recognize the greatness of the benefit conferred on legitimate medicine by the recent acts of the Scottish Colleges, I cannot help feeling that we ought to do more than, as individuals, yield to them our concurrence and applause We ought not, I think, to allow our annual meeting at Brighton to pass without issuing a deliverance upon the subject of homœopathy, as explicit as those which have come to us from beyond the Tweed; and there is one point upon which it appears to me that even more plainness of expression is required.

To adopt resolutions setting forth that the homœopathic dogma, and the doctrine of infinitessimal doses, have no truthful basis, and are, in fact, mere nonsensical delusions, may be quite proper, inasmuch as some honest but weak and undisciplined minds have been seduced by the hardy assertions and false reasoning by which these errors have been supported. But something more is required, if it be true, as I think it is, that this fashionable quackery is so susceptible of adaptation to the most contradictory prejudices of shallow men and women, as to have become a sort of Protean deceit, able to lure lucre by every imaginable wile from the sick and the silly. The worst part of homœopathy is, in my opinion, the DISHONESTY of the majority of those who live by it. When patients are once secured, they are, I think, very rarely treated in accordance with the principles of Hahnemann; but are retained by the combination of every current medical novelty which may at the time be most in favour with the monied throng of quack fanciers. I have not been able to hear of any one who honestly relies on homœopathy for the cure of disease; but I can point to many calling themselves homœopathic practitioners, who attempt to relieve the symptoms of disease by the same means which we would adopt, and to others, who retain their *clientelle* fully as much by practising hydropathy, mesmerism, and miscellaneous tricks, as by giving the globules. If homœopathy were honestly practised, it might be amicably dealt with; but as it is truly a combination of any and every available charlatanic trick, it cannot be effectively opposed as a distinct medical heresy, and therefore all that remains for us, as men of science and men of integrity, is to give notice, that we exclude from all professional intercourse practitioners who are in any way engaged in using or upholding a system which we think bears upon its very face fraud as well as absurdity.

I have heard it urged in extenuation of the fall of some medical men, that they had large starving families, and that they had met with distressing pecuniary reverses. It has often been said to me that if they treated disease to the best of their ability, there was no great crime in their sailing so far with the fashionable current as to call themselves homœopathic, and to give globules as placebos. From my heart I compassionate these persons; for I know that want has distorted and destroyed the moral sense even in good men; but, while in some cases we pardon the transgressors, let us not be tolerant of the transgression. It behoves us, quickly and decidedly, to draw a broad line between medicine and homœopathy, so as to encourage and strengthen the hands of many in our impoverished and overstocked profession, who, though tempted, have not yet bartered principle for pelf.

The Provincial Medical and Surgical Association has now the power, and the near opportunity, of drawing this much-needed line of demarcation:—*Let the Association declare that the names of homœopathic practitioners, and of those who hold professional intercourse with them, cannot be on its list of members.* The promulgation of this law would enlighten the public, It would also deter some too-facile consulting physicians from meeting the homœopathic quacks "simply for diagnosis;" and it would make it impossible for operating surgeons to say that they did not mean to insult the profession, "that they only went to give a surgical opinion" or "perform an operation." When it is known that such unworthy proceedings are of daily occurrence in London; and when we see Fellows of our metropolitan colleges eagerly seeking as the patrons of their hospitals Lord Carlisle, Lord Robert Grosvenor, and other noblemen, who are notorious abettors of homœopathic charities, is it wonderful that the public mind has become poisoned, and unable to discriminate between legitimate medicine and fraudulent practice? When we see Fellows of both London colleges so demeaning themselves, how can the colleges serve the cause of truth? In these circumstances it is doubly the duty of our great Association to come forward; and when we meet at Brighton let us make the fact of membership be a more distinctive test of professional morality than any now existing out of Scotland.

I am, Sir, your obedient servant,

JOHN ROSE CORMACK.

Postcript.—As the following recent correspondence illustrates some of the points to which I have adverted, perhaps you may think it worth adding as an appendix to my letter. I will thank you not to print the names of persons or places.

No. I.—A. B., Esq., to Dr. Cormack. July 12, 1851.

My dear Sir,—As you are aware that I have been for some time much impressed in favour of homœopathic

medicines, I hope you will not think me actuated by any want of confidence in your professional skill and careful treatment, if I wish to place my baby under a different system of medicine. I can assure you it was from the high opinion we have entertained of your professional knowledge that led us, in spite of our loss of faith in the ordinary medicines, to ask you to attend the baby, but we find ourselves unable longer to resist the desire to adopt homœopathic medicines, especially as we feel that *that* is the only change we could make in our leaving ———, which we shall do at the end of this month. We feel ourselves very much indebted to you for your particularly kind attention to, and treatment of, Mrs. A. B., which will always cause us to remember you with great regard. Although we are putting the baby under what you may consider a proscribed system, we can assure you that Mrs. A. B. will at all times have the same pleasure in seeing you. I have written what I conscientiously feel, and I hope you will always consider me as yours very sincerely and obliged, A. B.

P.S. Mrs. A. B. begs me to add, that if you are at ——— to-day, she will be glad to explain our feelings towards you, more fully than I have in this note.

No. II.—A. B., Esq., to Dr. Cormack. On same day.

My dear Sir,—It has just occurred to me that, as I did not say otherwise in my note of this morning, you may, perhaps, conclude that we considered the baby's state, and your treatment of her, unsatisfactory. This is not so, as she is no doubt, under the circumstances, as well as we could expect; but I have from the beginning of her attack feared any complication of the head or lungs, and felt that in such an event I could hardly change the treatment, although I should have had very great apprehension as to the efficacy of the remedies at your command. I wrote and left home hurriedly this morning, so I do not know if Mrs. A. B. will mention this, should she see you. Again believe me to be yours sincerely, A. B.

No. III.—Dr. Cormack's answer to A. B. On same day.

My dear Sir,—Having yesterday stated to Mrs. A. B. that I expected baby to go *safely* (though to me and to her very *anxiously*) through her illness, and as I thought that I had on good grounds and successfully relieved Mrs. A. B from the idea of any present danger, I was not prepared for your first letter, which I got before I left home in the morning. Your second I have just received. Entertaining the opinions which you hold regarding the sources which I have at command, as compared with others which you can obtain, you have properly performed your duty as a parent; and I receive your letters in the same kindly spirit in which they were written and intended.

You are right in stating that I regard homœopathy as a "proscribed system;" but I would not have you to believe that my principal objection to it is its non-acceptance by scientific men, after a thirty years' discussion. The homœopathic dogma has, as far as I can see, no adequate basis to rest upon; and the doctrine of infinitessimal doses is immeasureably beyond the grasp of my intellect. For these reasons I cannot assent to them. But it is upon far higher grounds that I consider homœopathic practitioners, as a body, justly proscribed; and at last divorced publicly by the College of which I have the honour to be a Fellow.

Homœopathics stand convicted by their practice of being disbelievers in the doctrines on which they found their claims to be regarded as superior to the Colleges; and so ill disguised of late has been the want of accordance between their principles and their practice, that homœopathy has become in England nothing more than a conventional appellation for a very clever quack system—one of the many which from time to time arise, and fasten themselves parasitically to the science of medicine, filling the pockets and cankering the integrity of not a few of its nominal cultivators. A good many patients have come to me from homœopathic doctors; and I have thus discovered that even the commonest and the coarsest of the "ordinary" means of cure are habitually used by them. Castor oil and aloes are advised in the ordinary purgative doses; camphor is given in very large doses in the same circumstances in which I would administer it; croton oil is used as a counter-irritant; cod-liver oil is relied on in some forms of phthisis; and in several cases of disease I have actually found that, with the globules, hydropathy and mesmerism were had recourse to! There is nothing here stated but what I can prove to be true.

But let me remind you of the circumstances of Mrs. A. B.'s case when you first called me in to take charge of her, on the 17th of May, last year. She had been under a gentleman described by you to me as a homœopathic obstetric physican, whose name, however, I do not now remember. I found that, in addition to the globules (containing, as was to be supposed, the billioneth or trillioneth of a grain of some medicinal agent), she was taking regularly, under the direction of her homœopathic (?) adviser, boluses of a purgative paste, which from its taste I perceived to be principally composed of Barbadoes aloes; and she was also using as a lotion a strong solution of alum. I then stated, that, granting the infinitessimal doses had any power, it was impossible to assign to them their share in any effects produced, if other and powerful remedies were used along with them, such as the aloes and the alum; and that it seemed very odd to regard the latter as mere "adjuvants," the other medicines, from some unexplained cause, being regarded as the truly potent and beneficial. I looked upon the globules as non-essential and charlatanic, and I therefore discarded them, but as I regarded the aloes and alum as required I continued them; adding, however, which seemed not less needed, ammonia, valerian, and henbane. I believe that very great good resulted from the system which was adopted both before and after Mrs. A. B.'s confinement; and from her having got through that trial so much better than on former occasions, I think there need be no question on this point. The use of iron by the eldest child also seemed to be attended with decided benefit; and I have always felt that although there was nothing but what was very "ordinary" in the practice adopted, it was signally successful. From these circumstances—from the complete and cordial way in which all my directions were carried out, from the very agreeable intercourse which we have had, and in particular from the very

kind exertions which you used in my behalf in the matter of ——, I can very sincerely reciprocate all the kind expressions contained in your letters. As you are not of my profession, we may very easily agree to differ on the subject of homœopathy; but that this difference may ever be thoroughly amicable, the best plan is, after this mutual explanation, to let the matter drop. *You* cannot convince *me* that homœopathy is true in theory, or that "the system," so-called, is honest in practice, or that it legitimately brings riches to starving doctors. On the other hand, *I* could not satisfy *you* that the facts of "the proscribed system" bear a less proportion to its astounding theories than Sir John Falstaff's halfpenny worth of bread to a gallon of sack.

We have both written what we conscientiously feel, and I hope you will always consider me as

Yours, very sincerely and obliged,

JOHN ROSE CORMACK.

No. IV.—Mrs. A. B. to Dr. Cormack. Some days later.

My dear Sir,—It struck me for the first time this morning, that you have possibly thought we had decided on, or at least contemplated, changing our baby's treatment, before I saw you on Friday, (4th July). I write to you immediately to assure you that this was not the case. We have often from time to time given the children a globule, and on Friday evening when Mr. A. B. came home, he was very anxious to give baby something, to see if it would relieve her cough; it appeared to us to do her so much good, that we resolved on Saturday to let her see Dr. ————, and to try homœopathy properly with her. I feel sure that you will excuse my troubling you with this explanation, as it would really grieve me if you thought I could speak to you as I did on Friday, at the same time intending to act as we did on Saturday. You will, I think, like to hear that dear baby's cough has nearly left her, though she continues very weak, and has a bad appetite. I hope you will come to see us before we leave ———. I shall always feel grateful to you for your kindness to me and to the children. Believe me, my dear Sir, yours very sincerely, MATILDA A. B.

LETTER FROM DR. HILBERS, ON HIS DEFENCE OF HOMŒOPATHY.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—Having been absent from home for a few days, the number of the *Provincial Journal*, containing your strictures on my letter, only fell into my hands a day or two ago. As you have impugned my conscientiousness, I trust you will not deny me a place in an early number of the *Journal*, in order that I may point out the error in your article to which, as I conceive, your remarks are mainly attributable.

The "sophisms" which you are pleased to call mine, are of your own manufacture. My "sophisms" are quite different, and are not touched by your article. You say,—"He admits, in fact, that equivocation is justifiable when it is necessary to obtain a certain end." I say,—"If a set of men can be found so blinded by prejudice to a sense of their duty, as to punish a man because he knows all that they do, and something more, any reasonable amount of deception is justifiable, when the object to be attained is a laudable and a necessary one, and *when, through their dishonesty*, it cannot be obtained without it." I would suggest that there is some slight difference between the qualified and the unqualified assertion; about as much as if you were accused of justifying assault and battery in the abstract, because you had said that if a man assaulted you, and tried to take away your coat, you would feel yourself justified in knocking him down. Methinks it seems passing strange, and somewhat inconsistent, for so stern a moralist to fall into such an error and consequent injustice, for I presume it is not a part of your moral creed that it is unnecessary for "a Christian and a gentleman" to act fairly and honestly to a heretic.

If you desire fairly to put the question to your clerical adviser it would run thus:—I am in want of a distinction which the State has empowered a University to bestow on all candidates who comply with certain conditions. I *have* complied with those conditions, and consequently consider myself legally and equitably entitled to the distinction. But some members of this University, in order to gratify a blind prejudice, based on ignorance, have illegally and arbitrarily appended certain other conditions never contemplated by the State, and diametrically opposed to the genius of our institutions and the spirit of the age. Am I justified in answering in the third person, (the sum and substance, be it remembered, of Dr. Hale's delinquency, and of my justification,) instead of the first, in order to evade these conditions. Despite your taunt as to my want of conscientiousness, I still think that such an act of "deception," if deception it can be called, is justifiable, exactly as I should consider the unfortunate red-haired prisoner, mentioned in my former letter, justified in going into court with his hair dyed black. The old English proverb—"what is sauce for the goose, is sauce for the gander," holds good here. If it is imperative on the homœopath to answer purely conscientiously, it is imperative on every other candidate to do so too. Considering the diversity of opinions which exist in the treatment of disease, any examination on such terms would be impossible. Every man would naturally contend for the correctness of his own views; the examination room would speedily be transformed into a bear-garden, and the police office, or the riot act, would be the *finale* of every examination. The examination always has been, and always must be, a test of a man's knowledge, and not of his creed. If he is found to possess a competent share of the former, he ought to be presumed capable of correctly determining the latter.

As to the members of the University deciding that homœopathy is a mischievous fallacy, it is not surprising, when it is remembered that it is something new, and that they are quite ignorant about it. Granting for a moment that the system is as true as its warmest advocates assert it to be, how is it possible that either you or they can ever be convinced of its truth so long as you refuse to test it, or to believe a word spoken in its favour by those who have tested it? To talk in a grandiloquent style about its not being worth testing, and of its having been refuted over and over again, is

simply absurd. There are plenty of writers in your own school who would deny such assertions. Dr. Andrew Combe, for instance says:—*(British and Foreign Med. Review*, vol. 21, page 521) "If I were now in practice I should hold myself bound, without further delay, to test its truth by careful and extensive experiments." Again, to compare it with Morrison or Holloway, is worse than absurd, for surely no useful analogy can be drawn between a system which is supported by thousands of competent authorities, (educated medical men,) and a single medicine which rests for support on the testimony of one or two interested persons. Read the fine philosophic views in the paper of Combe's above quoted, and then see whether such reasoning is applicable to homœopathy.

Depend upon it, Sir, that whether homœopathy is true or false, the course pursued by the periodical medical press is alike impolitic and injurious to the respectability of the profession. The public are beginning to inquire into the matter, and it will be hard for the profession to come well out of the scrutiny. If you really believe homœopathy to be a "mischievous fallacy," you ought to urge on your readers to set to work to expose it without delay, by experimenting honestly with their medicines, and publishing their failures. You should tell them that what has heretofore been called refutation, (in other words, abuse and calumny,) has been tried for sixty years, and has most signally failed;—that homœopathy to-day is more rampant than ever;—that, therefore, the further reliance on these weapons is hopeless;—that nothing can be expected from persecution;—that that also has been tried and found wanting;—and that if despotic Austria was obliged to abandon it, it is scarcely probable that the miserable efforts of the Scotch Universities in the same direction will answer better. Wonderful to say, however, the unwillingness of the profession to enter on our destruction in the way which (if we are wrong) would insure success, is only equalled by *our* eagerness to court this destruction. We open hospitals, we put every facility in the way of medical men attending them, we say to our bitterest enemies—come, and welcome. On the present occasion I have tried to bribe the profession to expose us, by offering a twenty guinea prize, (I will make it forty if you please,) for the best series of cases illustrative of the failure of the treatment, but all to no purpose. You fall back on the old tactics, and solemnly pronounce your deliberate conviction, that out of two or three thousand medical men not one has ordinary conscientiousness and intelligence combined. And you say this, although many of these men have made the greatest possible sacrifices, personal and professional, in embracing homœopathy; and though they have enlisted on their side such men as the scientific Chevalier Bunsen, the logical Archbishop Whateley, and the hard-headed statistician Wilson. Verily, Sir, the extreme of scepticism is the quintessence of credulity.

I am, Sir, yours obediently,

GEORGE HILBERS.

19, South Bedford Street,
July 29, 1851.

Medical Intelligence.

THE LAW OF LUNACY.

On Thursday, the 17th ultimo, a meeting of the "Association of Medical Officers of Hospitals for the Insane" was held by appointment at twelve o'clock, at the Freemasons' Tavern. Dr. Conolly, being the senior member of the Association, was voted in the chair. The following members, with others, were present:—Dr. Bucknel, of the Devon Asylum; Dr. Huxley, Kent Asylum; Dr. Stewart, Belfast Asylum; Dr. Huckle, Asylum, Oxford; Dr. Kirkman, Suffolk Asylum; Dr. Boyd, Somerset Asylum; Mr. Diamond, Surrey Asylum; Mr. Prosser, Asylum, Leicester; Dr. Fox, of Northwood; Dr. Munro, of Bethlem; Dr. Lloyd Williams and Dr. Nesbitt, of the Northampton Asylum. The Association has been in operation some years. The meetings have hitherto been held in the provinces, at or in the neighbourhood of the various County Asylums. It was, however, determined this year to summon a meeting of the Association in London in order to afford the members living in the metropolis an opportunity of discussing with their provincial friends some important matters of business.

As a preliminary matter, the question arose as to the organization of the Society. The Association has always met annually in the provinces, and has been confined to medical gentlemen officially connected with County or Public Lunatic Asylums. It was proposed and carried that the medical proprietors of private Asylums should be eligible as members; and a number of gentlemen were immediately elected. It was also resolved that for the future the annual meetings should take place in London, in the second week of July; and that the members of the Association resident in or near London should hold quarterly meetings in the metropolis for the despatch of business.

The condition of the criminal lunatics was then brought under the notice of the Society by Dr. Conolly, and after a long discussion, in which Drs. Boyd, Nesbitt, and Winslow took a part, it was agreed to present a petition to Government for the establishment of an institution, apart from Bethlem, exclusively for the reception of persons acquitted of crime on the plea of insanity. The unfortunate, desolate, and unhappy condition of the criminal lunatics was feelingly dwelt on by all the speakers, and it appeared to be the unanimous opinion of the Association that sufficient attention had not been paid to their state. It was thought that great good would result from the separation of the criminal from the other lunatics confined in Bethlem and other public asylums. The state of the law relating to the insane was then fully discussed. It appeared to be opinion of the Association that the Lunacy Acts were greatly defective, and that the whole of them required careful revision. Nearly all the speakers pointed out most glaring errors in the construction of the Acts of Parliament bearing upon the management of asylums and the care of the insane. It was proposed that a Committee of five members of the Association be formed to consider the subject. The following gentlemen were nominated:—Dr. Corsellis,

Dr. Conolly, Dr. Forbes Winslow, Dr. Boyd, and Dr. Nesbitt. It was also proposed and carried that Dr. Winslow should be appointed Secretary to the Committee; that he should communicate with the various members of the Association, and obtain from them suggestions as to the amendment of the law, and embody them with his own views in an official shape, for the consideration of the Government and the Commissioners in Lunacy. The inquiry which Dr. Winslow was authorized by the Association to make was to extend to all the Lunacy Acts, embracing also the enactment relating to the administration of the property of lunatics, which was considered unjust and defective in its operation.

After the despatch of other business, the Association agreed in a body to visit Colney Hatch and the Surrey County Asylum, with the view of inspecting their arrangements.

The first quarterly meeting of the Association is to be held in London early in September, when important matters of business are to be considered.

THE ROYAL COLLEGE OF PHYSICIANS.

The portals of this College, which have, until lately, appeared hermetically sealed in their aristocratic stateliness, were thrown open, for the second time this season, on Wednesday evening; and to the great gratification derived from the former *soirée* was doubtless to be attributed the large number of visitors, both home and foreign, who assembled on this occasion. To the genial influence of this eventful year may be attributed the dissolution of many barriers to social intercourse, and in the College of Physicians the effects were visibly pourtrayed in the kindly manner in which the President and Fellows received their guests; nor was it difficult to perceive, that mutual recognitions and exchanges of courtesy formed the staple of the hour. The floral decorations throughout the various *salons* were displayed in excellent taste, added to which, the brilliant mode of lighting the grand library greatly facilitated the observation of such objects of interest as covered the tables, and gave additional effect to the charming *coup d'œil* from the gallery of the Museum. We cannot in justice omit a remark, *en passant*, on the profusion with which the supper tables displayed in elegant arrangement their tempting delicacies;—the greatest credit is due to the Messrs. Staples, on whom, we understand, this, not the least important, part of the entertainment devolved. We only hope the Council of the College of Surgeons will not fail to profit by the example afforded them, and render their public meetings more dignified and better worthy the object they seek to elevate. Among the company assembled we observed—the Duke of Newcastle; Lord Colborne; Bishop of Sodor and Man; Archdeacons Hale, Sinclair, and Burney; Sir Henry Ellis; Sir Wm. Newton; Sir Benjamin Brodie; Sir James Ross; Sir Charles Fellows; Sir James South; Sir John Herschell; Sir Charles Young; Lieutenant-Colonel North; Captain Sibthorpe; Judge Patteson; Sir Frederick Thesiger; Sheriffs Carden and Hodgkinson; Seyd Abdoolah; Baron Homfeldt; Don José de Odriozola; Don Miguel de Odriozola; Don Cubi y Solis; Dr. Pantaleone; Father Gavazzi; Professor Pattison; Rev. Drs. Russell, Croker, Plumptre, Major, Richard Fayle, Edwin Fayle, R. N. Russell, Babington, Rowlatt, Williams, Mr. Pusey, M.P.; Mr. Gladstone, M.P.; Mr. Hastie, M.P.; Mr. Goulbnrn, M.P.; Mr. Jacob Bell, M.P.; Hon. Charles Villiers, M.P.; Mr. Pickersgill; Mr. David Roberts; Mr. Copley Fielding; Sir Richard Westmacott; Doctors Paris, Monro, Hawkins, Alison, Hue, Merriman, Tyler Smith, Dew, Henry Monro, Sieveking, Walshe, Babington, Roberts, Balfour, Blacklock (of Dumfries), Malcolm (of Edinburgh), Benjamin Bell, Quain, Jenner, Bushnan, Hodgkin, Turley, Thomson, Reid, Diruf, Lee, Coxe, Toogood, Scholfield, Goodfellow, etc. etc.—*Medical Times.*

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted on the 18th ultimo:—Charles Le Gay Bereton, Beverley, Yorkshire; John Page Cooper, Coborn Road, Bow, Middlesex; John Edward Davies, Stone's End, Southwark; Michael Cudmore Furnell, Pelham Place, North, Brompton; John Grabham, Rochford, Essex; Thomas Ligertwood, Foveran, Aberdeenshire; James Mudge, Bodmin, Cornwall; Robert Vaile Skinner, Headcorn, Kent; Charles Henry Tovey, Bermondsey Street, Southwark; Thomas Delamine Wheatley, Carlisle, Cumberland.

The following gentlemen were admitted on the 23rd ultimo:—Merrick Lloyd Burrows, Devizes, Wiltshire; Edward Davis, Thatcham, Berkshire; Frederick Wm. Headland, Guildford Street, Russell Square; James F. Henry, Royal Navy; Horace F. Howard, New Buckingham, Norfolk; George William Nichols, St. Ives, Huntingdonshire; John Henry Peacock Oldmeadow, Great Coram Street; John Douglas Tapin, Barbadoes; William Warke, Liverpool; William Robert Woodman, India.

The following were admitted on the 25th ultimo:—James Hobson Aveling, Rochester, Kent; George Burnham, Great Grimsby, Lincolnshire; David Daniel Davies, Carmarthen; Francis Godrich, Brompton, Middlesex; Robert Joseph Hodges, Barrington, Dorset; John Langdon, Bampton, Devon; William Cecil Lovell, St. John's Wood; Frederick Pratt, Swimbridge, Devon; Richard Richards, Carnarvon, North Wales; John S. Sanderson, Newcastle-upon-Tyne; Willoughby Francis Wade, Derby.

The following were admitted on the 28th ultimo:—Arthur Adey, Hon. East India Company's Service, Madras; Edward Ashton, Boston, Lincolnshire; Herbert Beresford, Chesterfield, Derbyshire; Henry Bond Ware, Herts; Charles Wm. Chaldecott, Dorking, Surrey; James Crawford, Belfast; Jeremiah Cronin, Cork; Southmead Langworthy, Modbury, Devon; D. Leman, London; William Henry Yates, Stroud, Gloucestershire; Henry William Wood, Royal Navy.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, the 24th ult.:—Henry Gregory King, Kingston; George Wise Mackenzie, Maidstone; Thomas Joseph Wm. Marsh, London; William Parater, Exeter.

TO CORRESPONDENTS.

Communications have been received from Mr. Lawrance and Mr. McNab.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL
MEDICAL & SURGICAL ASSOCIATION.

NINETEENTH ANNIVERSARY MEETING.

THE Nineteenth Anniversary Meeting of the Association was held at Brighton, on Wednesday the 13th, and Thursday the 14th of August, 1851.

The following gentlemen recorded their names in the book kept for that purpose. There were present altogether about 300 :—

F. R. Horner, M.D., Hull; James Crang, Esq., Timsbury; Wm. Newnham, Esq., Farnham; J. R. Beddome, Esq., Romsey; Frederick H. Sankey, Esq., Wingham; Robert Wake, M.D., Southwold, Suffolk; George Bottomley, Esq., Croydon, Surrey; Sir Charles Hastings, M.D., Worcester; J. Conolly, M.D., Hanwell; Caleb Williams, Esq., York; William Conolly, M.D., Hayes, Middlesex; Thomas Thomson, M.D., Stratford-on Avon; Thomas Workman, Esq., Basingstoke; Archibald Robertson, M.D., Northampton; James Stedman, Esq., Guildford; Harrington Tuke, Esq., Chiswick; Charles B. Nankivell, M.D., Torquay; Arthur Stilwell, Esq., Hillingdon; C. W. Crowdy, M.D., Brighton; Charles Lord, Esq., Hampstead; Edwards Crisp, M.D., London; Benjamin Vallance, Esq., Brighton ; John Lawrence, Esq., Brighton; Nicholas Tyacke M.D., Chichester; Allen Duke, M.D., Chichester; Edmund Lyon, M.D., Manchester; J. Cordey Burrows, Esq., Brighton; George Royde, Esq., Brighton; Thomas B. Horne, Esq., Brighton; H. D. Carden, Esq., Worcester; William Chalmers, M.D., Croydon; John Rose Cormack, M.D., Putney; John Colthurst, Esq., Clifton, Bristol; C. Radcliffe Hall, M.D., Torquay; John Propert, Esq., London; S. Hare, Esq., London; Thomas Paget, Esq., Leicester; H. Davies, M.D., Brighton; J. M. Cunningham, M.D., Hailsham; J. Taplin, Esq., London; Peploe Cartwright, Esq., Oswestry; Thomas Smith, Esq., Crawley; Joseph Hickman, Esq., Brockton; Thomas Bell, Esq., Great Grimsby; Henry Hopkins, Esq., Brighton; G. B. Knowles, Esq., Birmingham; J. Churchill, Esq., London; John S. Bartrum, Esq., Bath; Francis Henry Woodforde, M.D., Taunton; John Hatton, Esq., Manchester; C. R. Bree, Esq., Stowmarket; John Lawrence, Esq., Brighton; W. A. Greenhill, M.D., Hastings; J. M. Bean, Esq., Peckham; H. R. Fawcett, Esq., Brighton; B. Thos. Seabrook, Esq., Brighton; Henry Ewen, Esq., Long Sutton; Robert Ceely, Esq., Aylesbury; Thomas Smith, M.D., Cheltenham; William Addison, M.D., Maidstone; Francis Sibson, M.D., London; Thomas Henry Starr, M.D., Brighton; Harry Mills Blaken, Esq., Brighton; H. Martin Holman, M.D., Hurst-Pierrepoint, Sussex; J. Edwards, M.D., Chester; Peter Martin, Esq., Reigate; Alfred Barrow Jones, Esq., Brighton; Edward Pope, Esq., Tring; Samuel Crompton, Esq., Manchester; G. M. Humphry, Esq., Cambridge; Joseph McCarogher, M.D., Chichester; John S. Soden, Eeq., Sunbury, Middlesex; Joseph Toynbee, Esq., London; A. Napper, Esq., Guildford; Charles West, M.D., London; James Tunstall, M.D., Bath; W. H. Ranking, M.D., Norwich; Forbes Winslow, M.D., London; R. Rugg, Esq., Brighton; John Soden, Esq., Bath; William Davies, M.D., Bath; William Church, Bath; George Norman, Esq., Bath; James Yearsley, Esq., London; Henry Moon, M.D., Lewes: Jas. A preliminary meeting of the Council was held in the Board Room of the Brighton Dispensary, Queen's Road, at eight o'clock on Tuesday evening, and the

FIRST GENERAL MEETING

was held in the Music Room of the Pavilion, on Wednesday morning, at ten o'clock. There was a large gathering of the profession. The proceedings commenced at eleven o'clock, when

Sir CHARLES HASTINGS rose and moved that Dr. Horner of Hull, take the chair. (Applause.)

Dr. HORNER complied, and then, addressing the meeting, said,—

GENTLEMEN,—I beg to acknowledge the honour you have done me. I do, however, resume the chair but for the purpose of inducting thereto my successor, Dr. Jenks, and I congratulate the Association that their choice has fallen upon one whose experience and ability so well befit him for the office. As it is not according to the usages of the Association that the retiring President should address you, I shall be very brief in my remarks. In the first place I cannot refrain from the pleasure of congratulating you that your Association has by no means halted in its prosperous career; nay, that during the year of my own presidency some very important measures have been consummated, measures which this Association has long and arduously laboured to attain; these will be more especially alluded to, either in the report from the Council, or possibly by Dr. Jenks himself, and it would not be fair for me to forestal those observations. I think, gentlemen, that we have much cause for satisfaction at our present position; let us not, however, I beseech you, therefore be content—be satisfied—with where we now are, for we know that these are days of progress, of onward movement, of discovery. To put forth only exertions which we have been in the habit of putting forth, would really be to stand still, which would be to retrograde, to be left behind in the great intellectual march. No, gentlemen, I say there is greater cause than ever for your exertions, and as the eagle is fabled to fix its piercing gaze on the sun, and thitherward unswervingly to cleave his course, so let the light of knowledge, the good of mankind, and the advancement of science, be as it were the shining beacons of your course. With an eye that is single, and a purpose that is determined, be your course like the eagle's—onward, right on. There is one subject to which I will only cursorily allude, and which will be laid before you by the Council; it is one, however on which I have strong personal feeling, and which I cannot in my office of retiring President, refrain from just alluding to, I mean the sad bereavement which we have sustained in the death of Dr. Mackness. He was my sincere friend. No man valued him more highly than myself. But a week before his death he wrote me expressing his congratulations at the thought of reading an address before you in this room, on this day. This question is a very serious matter; it is one calculated to give rise to serious reflection. It is true here is the audience collected, but where is the lecturer? *Sub cespite jacet.* I say this does give us a reason for now doing our duty in that state of life to which we have been called. If we are willing to exert ourselves for the benefit of our fellow-men, and for the great objects of the Association, now is the time that we should do it. Such a painful event also naturally awakens in the mind other feelings of a far more important nature to which it would be inopportune in me, at this meeting, to allude. The words of Dr. Young occur to my mind as most applicable:—

> "Whose grave prescribes the best? A friend's.
> And yet, from a friend's grave how soon we disengage!
> E'en to the dearest, as his marble cold.
> Why are friends ravished from us?—'Tis
> To bind, by soft affection's ties, the human heart
> To thoughts of death, which reason, too supine,
> Or misemployed, ne'er fastens there.
> And yet nor reason, nor affection, nor both combined,
> Can break us from the witchcrafts of this world!
> The inexorable hour,—how near at hand!
> The inexorable hour,—how soon forgot!
> Nay, to forget it, the chief aim of life,
> Tho' well to ponder it, is life's dire end."

We have now specific duties before us; and whether I look at the magnificent arrangements which have been made for you, or whether I look to the high character of our medical friends at Brighton, or whether I look at our Association now in all the vigour of its nineteenth year, I am sure I can safely promise you a most happy, and a most prosperous meeting, which I now most cordially wish you.

Dr. JENKS at once proceeded to take the President's chair, and then addressed the meeting as follows:—

GENTLEMEN, —When I look round upon this assembly, composed of members of a learned and scientific profession, many of whom by the force of intellectual zeal and power have risen to distinction in the highest walks of literature and science, as well as in the various branches of medicine and surgery, and, consider, that I have been nominated to preside over so distinguished a body, I feel deeply sensible, I assure you, of the great honour conferred on me; but unaccustomed as I am to fill so high an office, I hardly know in what terms I can make my acknowledgments acceptable. I must entreat you, therefore, to receive my best thanks as kindly and favourably, as I tender them cordially and gratefully.

In entering upon my office, gentlemen, believe me, I have no little mistrust of my ability through inexperience, to fulfil the duties thereof in a manner adequate to my own ideas, much less equal to the expectations of such an audience. I must, therefore, crave a larger share than usual of that indulgence and support which you always readily accord to your Presidents. I know well, on looking at the names and qualifications of those gentlemen who have already filled this chair, that there is no lack of admirable and excellent examples to all who may come after; but this very excellence it is, which augments the difficulties of their successors. In all posts of honour men are excited to do their best. There is a not unbecoming pride in doing more than was expected of us, and not less than others would have done, but with such an array of distinguished predecessors before me, in all humility, and sincerity, I regard the latter hope as unattainable. I must be content to follow, *haud passibus æquis*, those eminent persons who, with so much dignity and ability, have conducted the deliberations of these meetings on former occasions, and shall think myself well rewarded if I succeed in imitating their example to your satisfaction; if not, I feel persuaded you are generous enough to accept the intention favourably, and to think there may be even some merit in the earnestness of my endeavours.

We are now met to celebrate the nineteenth anniversary of the Provincial Medical and Surgical Association, and the numbers assembled here this day abundantly testify to the continued prosperity and importance of the Society. Great have been the benefits conferred on its members in the diffusion of knowledge, in the union of thoughts and interests, in the interchange of kindly offices—and, I think I may add, that faithfully and extensively has the General Association been seconded in this good work by the local branches.

It was happily and wisely determined, by the honoured founder of this Institution, to collect his widely scattered associates, year by year, into one place, where minds overwrought by the cares, anxieties, and Sisyphean labours of a busy harassing profession, might forget awhile their ever-recurring toil, and indulge freely in well-intentioned and dignified sentiments and communion, by which manners are improved, character is exalted, mutual esteem generated, and good fellowship established and strengthened. Besides the cultivation of the social virtues, we gather other fruits from these meetings. We learn the advantage of combination and concert for the advancement of professional objects and for public ends. The difficult and much vexed questions of medical reform, the unrestricted sale of poisons, the state of health of the people, together with the legislative measures needful for their improvement, have occupied your time and been maturely and deliberately considered.

Deputations from the Provincial Medical and Surgical Association have been received by those in authority with marked respect, and listened to with becoming attention. The resolutions formed at your meetings have taken effect, your reports been approved, and your suggestions upon legislative improvements adopted. In proof of these remarks, we may refer with satisfaction to the spirit of conciliation manifested by the Council of the College of Surgeons in their recent concessions; to the Sale of Arsenic Regulation Bill, and to the impulse given to sanitary improvements all over the country.

Furthermore, as an important auxiliary to your proceedings, you have a well-established, most ably conducted, and excellent *Journal*, which registers your deeds, publishes original essays, treasures up valuable facts, and is at once a channel for mutual correspondence, impartial criticism, and useful intelligence. The volume of "Transactions," published yearly, I may say, without fear of contradiction, deserves a place in every medical library in the kingdom.

But neither are social advantages, nor science nor medical polity, exclusively the objects sought for and obtained on these occasions. From the bosom of these meetings there emanated that excellent and charitable idea of a "Benevolent Fund," for the relief of distressed and decayed members of the profession, and the widows and orphans of those deceased. In this beneficent cause, I might be pardoned for addressing you at the length it deserves—but I forbear. At the proper time this subject will come before you, adorned with the moving eloquence and urged with the fervent zeal which have distinguished its able advocate, the Treasurer and Secretary, upon all former occasions. To him belongs the task, *magnum munus atque onus*, of appealing to you in behalf of our poorer brethren, and well persuaded am I that he will not do so in vain. Suffer me merely to remind you, that poverty is an evil bringing in its train so much trouble, peril and misery, that while every man should strive to avoid it, he ought at the same time to help, as far as he is able, those whom the gripe of necessity has reduced to destitution. Indeed this can hardly be considered a duty that we can do or leave undone as we list, for many are they who stand in utmost need of our bounty. And shall the reproach be cast upon us that we do not readily assist one another? Upon us! the members of a profession of whom, it was said by Dr. Johnson, that "every man has found among them great liberality and dignity of sentiment, very prompt effusion of beneficence, and willingness to exert a lucrative art, where there is no hope of lucre."

If we look heedfully at the condition of many of our poorer brethren, especially in the rural districts—overworked, badly remunerated, cruelly oppressed by hard task-masters, or perchance ruined by the reckless competition of interlopers, we shall see abundant necessity for a Benevolent Fund. Much of this evil is to be attributed to the adverse administration of the Poor-Laws. It would have given me great pleasure if I could have announced any improvement in the relative position of medical Union officers and their oppressors—the guardians of the poor as they are called; but I am sorry to say that the Committee of the Convention of Poor-Law Medical Officers have suspended their meetings through want of support. After a statement of

their difficulties and proceedings, they conclude their report by urging "the Poor-Law Medical Officers and the profession in general to consider how much the redress which is sought, and for which so large a sacrifice of money, exertion, and time, has been made by some of their brethren, is within their voluntary grasp; but that it can never be hoped for so long as the degrading and ill-paid appointments are not merely accepted, but made the objects of eager competition."

Alas! how long will this spirit of rashness on the one hand and supineness on the other disturb our counsels and cast reproach upon our very name and calling. Let it be remembered that by this ruinous competition for Poor-Law appointments the real thrift and progress of the profession are seriously injured; that by undertaking more than they can perform medical officers share the guilt of neglecting the poor with the so-called guardians; that by receiving less than a just reward for their services they degrade themselves and damage not only the interests of their fellow-labourers with their own, but indirectly those of every practitioner in the kingdom. A competition, unlimited like this, degenerates into unlicensed selfishness, which can only be checked by judicious combination. These rival principles may both be considered useful when properly balanced. Some degree of honest rivalry or emulation is needful to develop the energies of mankind, and some degree of combination equally so to protect the interests of class or profession. The one is a duty we owe to ourselves, the other to our neighbours. The remedy for this debasing system of Poor-Law competition is chiefly in the hands of the Union Officers themselves; but much might be done by a Government acting upon public principles for the public good, and especially the good of the indigent poor, who in the main are the greatest sufferers by these irregularities.

From this discouraging state of things, however, let us turn to the subject of Medical Reform, which at length affords a better prospect. In the opinion of most thinking and well-informed men, the question of medical reform is now ripe, and probably none the worse for having been hitherto withheld. It has been cast into the crucible of public discussion and has come out purified and separated from much dross. The contending parties are now wiser and better disposed to treat upon equitable terms. Upon this ground, therefore, we may look with more sanguine hopes than heretofore; with hopes, I would fain believe, well and solidly founded, that all parties, seeing the propriety of needful concessions, will concur in a plan of practicable and useful reform, which shall have for its basis the principles contended for by this Association, and on various occasions so ably advocated by the President of the Council and his colleagues. The consummation of these hopes, I am afraid, is not very near at hand; nevertheless, the good already effected is great; the progress though slow is assured. The moral certainty of some efficient reform should console us for its delay, for there is no fear of retrogression.

In the mean time, gentlemen, it behoves us all, and especially the junior members of our noble calling, to persevere steadily and diligently in cultivating the art and science of medicine; neither deterred by the difficulty of the study, which cannot be achieved without much labour and no triffling proficiency in the other sciences; nor discouraged by a degree of uncertainty pertaining to it, in common with many other branches of human knowledge. "Whatever can be said of the uncertainty of the art of physic," writes Sir William Temple, "or the disagreement of its professors, they may, I believe, confidently undertake, that when divines arrive at certainty in their schemes of divinity, or lawyers in those of law, or politicians in those of civil government, the physicians will do it likewise in the methods and practice of physic."

An earnest and truthful endeavour to improve our professional knowledge is the best foundation for public support, and the surest weapon wherewith to defeat the bold pretenders who rise up daily around us. Men of this description, whose maxim is, *ibi fas, ubi maxima merces*, have only themselves to serve, we our country and mankind. In such a cause our efforts are ennobled, and we should rather rejoice in being called to such a service.

Let not any man wonder that quacks and impostors should abound even in these enlightened days. They have abounded in all times and in all professions, and probably will never cease, for there is nothing so irrational or extraordinary that some men will not maintain for truth, feeling sure that the credulous, and ignorant vulgar, rich and poor, will receive it with implicit belief. We live in an age for example, supplying humble followers in great numbers to Mormonism, and educated *gobemouches* in crowds to Mesmerism.

It is not my intention to treat of the fashionable follies of the day—the mystifications and legerdemain of mesmerism, the unreal mockeries and sublimated jargon of homœopathy, nor the more dangerous excesses of hydropathy. All this has been admirably done lately by an accomplished member of this Society. I would observe merely that such aberrations from the path of true medical science should be adjured and repudiated with firm and solemn resolution, while the professors thereof may be left to an avenging Nemesis, which may one day or other overtake them. Let me, however, turn your attention to an evil which has developed itself within our own ranks.

"Iliacos intra muros peccatur et extra."

We have treachery within and war without. Open adversaries we know well how to deal with; but it is another thing when a man's foes are of his own household. I am grieved to hear that some, even of the legitimate sons of physic, are tainted with the leaven of these new doctrines, that others, like the bat in the fable, take either side as it may suit their purpose, while a few have not scrupled from indifference or crooked policy to countenance this defection, or to shield it by a sort of compurgation. Against this laxity of conduct the opinion of the profession should be unmistakably pronounced. To admit seceders, or

doubtful allies, to the privileges of regular practitioners, or to an equality in consultation, is the same sort of treason to the profession as the admission of the wooden horse into the walls of Troy. I trust enough has been said of late to induce those who have extended an ill-timed indulgence to these false brethren to withdraw from further communication with them, for we must never look for peace with quackery in any of its monstrous shapes; and as to the apostates themselves, it would be well that by a self-ostracism they quitted altogether the ranks of a profession which by a half-faced fellowship they dishonour and betray, lest, neglecting such admonition, they find at length "forbearance, no acquittance." Their secession will relieve us from much embarrassment, and their hostility will have no other effect than to strengthen our mutual confidence, improve our discipline, and excite us to increased exertion.

Now "great labour directed by great abilities is never wholly lost," and happily there never was more activity displayed, nor greater progress made than at the present time. The labourers in the field are skilful and numerous, and the harvest abundant. By the aid of chemical analysis, the microscope, and the stethoscope, by careful experiment, by patient and industrious observation, and a system of statistics based on numerical methods and averages, and what is of no slight importance, the co-operation of an active press, the advance in minute anatomy, physiology, pathology, diagnosis, and therapeutics, has been very considerable. In alluding to the press, I am unwilling to allow this opportunity to escape of paying a just tribute of praise to it generally, but to the medical periodical press in particular, which is not simply the channel of much useful knowledge and valuable criticism,—not merely a storehouse of important facts, but it constitutes a kind of censorship within the profession, and presents a formidable bulwark against all assailants from without. The thanks of the profession are due to the Editors of the medical journals generally for their exertions in behalf of the union surgeons, and also of the naval assistant-surgeons, and for their advocacy of the claims of the army and navy medical officers to a share in the honours distributed to their respective services. The meed of praise must be awarded likewise to the Editor of the *Lancet*, for the labours of the Sanitary Commission, which have scared the obscene harpies who defiled the food of the people, from their dishonest frauds and odious impositions. With such allies, therefore, and with resolution to work out our own purpose stedfastly and truly, we cannot doubt of the triumph that awaits us in the cause of true medical science. That cause which numbers among its chief supporters, besides the great names of antiquity, those master spirits of their time, Baglivi and Sydenham, Harvey and Haller, Boerhaave and Hoffmann, Heberden, the two Hunters, Baillie, Jenner, and many more. That cause of true medicine, I repeat, which the boasted wisdom of our forefathers has laboured to bring to perfection for two thousand years or more, but which, in the opinion of some modern sophists, has been overmatched with wondrous ease, in the leisure hours and sober intervals of Hahnemann!!

> "Can such things be,
> And overcome us like a Summer cloud
> Without our special wonder?

But enough of this theme. Let us turn to another subject more in harmony with your feelings. It has been usual, I believe, on these occasions to pass in review the characters and services of those members of the Association who have departed this life during the past year. It is good so to do, that we may derive therefrom matter for useful and solemn reflection. It is likewise natural that we should not allow those to whom we have given the right hand of fellowship to disappear from the scene of their earthly labours without casting one last lingering look of affectionate regard towards them. Time will not permit me to dwell upon the worth and merits of each individual; nor were it otherwise, could I perform that melancholy but grateful office through lack of needful information. But there is one whom I cannot pass over without paying to him the tribute due to a most able and zealous member of this Association; one who, had he been spared, would have been a principal contributor to the proceedings of this day. I do not take upon myself the office of biographer, but a short summary of the principal events in the life of our late lamented associate, Dr. Mackness, may not be unacceptable. In early life he met with some trials, and was beset with difficulties, which to many might have seemed insurmonntable. By dint of patient industry, frugality, and an excellent understanding, wholly unassisted by favour or fortune, he cleared the way at length to eminence, and made good his position. His was no exception, however, to the rule of the poet—

> "Haud facile emergunt, quorum virtutibus obstat Res angusta domi."

It would be foreign to my purpose to follow our late colleague through the difficulties he encountered, and so manfully overcame. I intend only to shew you that he sounded all the depths, and passed through all the tides of medical life. He began his professional career as a general practitioner in a country village, whence he removed to a larger field of practice at Northampton, but being unequal, through ill health, to the numerous and very arduous duties of general practice, he retired. In May, 1840, he went to St. Andrews, where he took the degree of Doctor of Medicine. In the year 1843, he became an extra-licentiate of the Royal College of Physicians, London. Soon after he had obtained his degree at St. Andrews, he settled at Hastings, where he continued to practise as physician till his death.

In private life he was beloved, and deservedly respected; he was a cheerful and instructive companion; his sentiments were solemnly religious, but elevated and liberal; his manners gentle and unassuming; his professional acquirements were of the highest order; to great skill and readiness in detecting and treating disease, he added good sense, urbanity, and benevolence. Though fully occupied in practice, he found time for several publications; he added to the stock of medical literature, (besides minor performances), a work on

"The moral aspects of Medical Life," containing a translation of the "Akesios" of Professor Manx. In this work of our late associate some inexperience in the art of composition is apparent, but it is rich in medical ethics, containing a judicious selection of facts, and abounding in interesting anecdotes. He wrote also a monograph on "Dysphonia Clericorum," a work displaying distinct and accurate views of a disease, not heretofore separately treated of, and manifesting great ability and judgment in the application of those views to practice. He was occupied in preparing a "Report upon the Medical Topography of Sussex," when the hand of death removed him from among us. Dr. Mackness died at the early age of 46, after a life spent in much labour and sickness. It may be said of him, as it has been said of another eminent physician, that "he worked out for himself an education, a profession, a reputation, and a competence."

I make no apology for detaining you awhile upon this subject, because I feel sure you think with me, that so much real merit in an associate now no more deserves honourable mention from the chair of this Association; but lest I trespass upon your valuable time I must be brief in what remains.

I should be much wanting to myself and to that obligation which the presence of so many distinguished persons imposes upon me if I delayed any longer to express the warm feelings which I know animate the hearts of all my colleagues, who, "on hospitable thoughts intent," I fear already reproach me for postponing it so long. Gentlemen, I have the greatest pleasure, in the name of the medical profession of this place, in bidding you a hearty, sincere, and perfect welcome to the town of Brighton. We thank you cordially for the prompt acceptance of our proposal to visit us on this occasion, and assure you it will afford us the highest gratification if the arrangements we have made for your reception should meet your approbation. We are all the more anxious to make your visit agreeable and your reception worthy of you as we cannot depend upon the local attractious of the place for any great help to your entertainment. The town, as you know, is quite modern: it may be said to have been founded by George IV., whose bronze statue, by Chantrey, adorns the centre of the Steine, and whose far-famed marine palace, now the property of the inhabitants, opens its portals to receive you. Though the town be of such recent construction, yet the place itself and the neighbourhood have been the theatre of some remarkable events. On the downs near Lewes—that is, on Plumpton Plain, a spot which, according to Ray, the naturalist, affords one of the most magnificent prospects in Europe—was fought, in 1265, the famous battle of Lewes, in which Henry III. and his gallant son, afterwards Edward I., were defeated by Simon de Montfort, at the head of the Barons. After this battle a Parliament was summoned, when, for the first time, cities and towns were required "each to choose and send two discreet, loyal, and honest men." Hallam observes, that after long controversy almost all judicious inquirers seem to acquiesce in admitting this origin of popular representation. When Brighthelmstone was yet a mere fishing village, Charles II., being hotly pursued after the battle of Worcester, embarked from the beach on board of a merchant vessel, commanded by one Tattersall, and escaped to France. The house is still standing in West Street, where Dr. Johnson visited Mr. Thrale, and recruited a shattered frame and overlaboured mind by a pure air and exercise, and some enlivening recretion. In the old church of the neighbouring village of Preston there is a curious ancient painting of the time of Edward I. on the eastern wall of the nave, the principal subject of which is the murder of Thomas a'Becket. This was discovered on removing some whitewash and plaster.

With the exception of the Pavilion, chiefly designed by Nash, of which you have now an opportunity of forming your own opinions, there are few public edifices upon a grand scale. Of the churches, that of St. Peter, by Barry, is the most to be admired for its correctness and beauty of style, and chasteness of decoration. The old parish church of St. Nicholas is interesting from its antiquity, its curious memorials of sepulture, and from its having been a landmark for mariners, being elevated 150 feet above the level of the sea.

Of the public works executed by the Commissioners, the Town Hall and the Market deserve notice; but the stupendous sea-wall, eastwards, is the greatest, and I trust will be the perpetual monument of their public spirit. Many important works have been projected and carried out by the enterprise of companies and individuals. Of these the Chain Pier is the most admired and frequented by strangers. Then follows the Railway Terminus, with its beautiful curved viaduct. The German Spa also deserves some special notice. The scientific process there employed for making the artificial mineral waters will be briefly explained by the resident Director. The grand reservoir of the Brighton Water Company is another construction of public interest. Near to it, on the Lewes Road, is the new Cemetery for extra-urban interment. On the hill above, called White Hawk Hill, supposed to have been a military station in ancient times, a handsome Race Stand has been recently erected by a few public spirited individuals. Among the public works I must not omit to mention the fountain on the Steine, and I would call the attention of the lovers of the fine arts to a beautiful altar-piece in the Roman Catholic Chapel by that celebrated sculptor, Carew.

The Institutions for charitable purposes are numerous. The Sussex County Hospital is a spacious building, with 120 beds. The original plan, however, having been upon a smaller scale, two wings have been subsequently added, and it is now found necessary to attach to it an additional building, which will contain a Chapel, Museum, and Library, and afford room for dispensing medicines and conducting the whole of the out-patient department. The ground on which the Hospital stands was given by the late Thomas Reade Kemp, Esq., and more has since been added by the Marquis of Bristol,

but the Institution itself was projected and magnificently endowed by the late Earl of Egremont.

"Clarum et venerabile nomen
Gentibus, et multum nostræ quod proderat urbi.

We particularly invite you to visit the hospital, and shall be happy to receive any suggestions for its improvement.

Next in importance, is the General Dispensary, a most useful Institution. The building is large and handsome, one room whereof contains the library of the Medico-Chirurgical Society of this town, and serves for their monthly meetings. This society was founded four years ago; it is in a flourishing state, and is very well supported. The Eye Infirmary is another valuable medical charity. We have, besides a self-supporting Dispensary, a Lying-in Institution; an Asylum for the deaf and dumb, and one also for female orphans. For purposes of education, besides various public establishments, and private schools without number, a College has been erected, the whole design of which has not yet been carried out, but when complete it will be a fine building. Beyond, and not far distant, is St. Mary's Hall, an admirable institution for the education of the daughters of poor clergymen.

At the Royal Literary and Scientific Institution, and at the Brighton Athenæum, lectures are occasionally delivered, and libraries are in the course of formation. At the former institution 360 original papers have been read. The population of Brighton, according to the census of the present year, is 65,000. The town is governed by 120 Commissioners, elected by the inhabitants, being householders of the annual value of £20. Sixteen of this body go out by rotation every year.

Gentlemen, it now only remains for me, in conclusion, to thank you most sincerely for the very indulgent and patient attention yon have vouchsafed me, notwithstanding my inexperience and slender ability; and to assure you, again and again, of the high sense I shall always entertain of the honour conferred on me by having been elected to this chair.

The SECRETARY next read the.—

REPORT OF THE COUNCIL.

In meeting for the first time the members of the Association in the South-Eastern District, the Council think they cannot more properly commence the Report which they are called upon to present to this, the Nineteenth Anniversary Meeting of the Association, than by expressing their great gratification that the establishment of the South-Eastern Branch has led to the gathering of the members together in a locality long celebrated for its attractions; and they at the same time offer their sincere congratulations to the Secretary of this Branch, that his laborious exertions in extending the Society in this portion of the provinces have been so successful. The state of the medical profession is such as imperatively calls for the further extension of the principles and objects for which the Association was founded; and your Council therefore rejoice greatly in every circumstance which has that praiseworthy tendency.

The number of members of the Association remains pretty much the same as at the last Anniversary. There have been many deaths during the year, and some retirements, but these have been more than compensated by the introduction of new members. The carrying out the resolution of last year, relative to the removal from the list of those who had neglected for a given period to pay their subscriptions, has reduced our number of members, with a benefit to the finances of the Society.

Publications.

The Committee appointed at the last Anniversary to consider whether any and what alterations may be advantageously made in the publications of the Society, have not given in any Report to your Council, but they are expected to do so on this occasion. Your Council have not, therefore, thought it prudent to make any alteration in the Editorial department of the *Journal*, and it is but a gracious acknowledgment of the labours of those gentlemen who conduct the periodical *Journal* to say that it has been a source of pleasure to your Council to have received during the year numerous communications from members, stating their satisfaction as to the ability with which the Editorial department is conducted.

"As respects the 'Transactions,' your Council are enabled to report the publication, at the termination of the last year, of the seventeenth volume—a contribution to medical literature of much value, and which will bear comparison with any previous volumes published by the Society. The Council are glad to have it in their power to state that the printing of the eighteenth volume is far advanced, and that as soon as time shall have permitted the papers that may be read at this Anniversary to be printed, another volume will be added to those already published by the Association, which it is hoped will be delivered to the members before the present year terminates.

Finances.

"Your Council have still to regret that many members are backward in paying their subscriptions, a circumstance much to be deplored, as it places your officers in a position of some difficulty, for they are thereby prevented being assured of the exact income of the Society. Notwithstanding this irregularity, your Council can report the finances in a sound state, and they hope that, by careful management of the funds which may come into their possession, the receipts will at all times be sufficient to meet the expenditure. The statement is as follows:—

	£.	s.	d.
Balance in hand, 1850	109	18	6
Receipts	1616	19	7
Expenditure	1632	14	11½
Balance	94	3	1½

Medical Reform.

This difficult question still remains unsettled, but the Council fervently hope that it is approaching a termina-

tion that may ultimately prove satisfactory to all parties. The present year has been distinguished by the Council of the College of Surgeons taking the lead in the adoption of a highly conciliatory course of conduct, for which they deserve, and have received, a meed of praise from all parties in the profession. This concession has very considerably lessened the obstacles which stood in the way of Medical Reform. There are, however, still some difficulties to be overcome, which require calm and careful consideration; but as all parties are now animated by an earnest desire that this long contention should cease, your Council cannot but look forward to the final settlement of the question at no distant day.

As soon as it was known that the Council of the College of Surgeons were prepared to yield so much, your Council communicated with many Members of the Association, and with the accredited societies, who had worked with them to obtain a legislative amelioration of the profession. The result of this consultation was, that it was deemed prudent by all parties to accept the proffered terms of the College, with some slight modifications. Your Council, therefore, thought it right to address the Secretary of State for the Home Department, and at the same time assured him that they felt gratified by the concessions which had been made by the College; they also reiterated the principles on which they considered any safe medical legislation should proceed.

Since the memorial no further step has been taken, as the near approach of the Anniversary rendered any further movement unnecessary. The Council, however. have thought it desirable to seek the opinion of the District Branches on the course they have pursued, and they are happy to say it has received their sanction.

Medical Topography.

The Council grieve to have to announce that the Report of Medical Topography will not be presented by Dr. Mackness. The hand of death has removed him from among us, and the Association has to deplore the loss of one of its most meritorious members. Dr. Mackness had at all times evinced much zeal for the success of the Association; and last year, at Hull, was foremost to take part in the endeavour to revive an interest for medical topography amongst the members. He was devoting much time to the subject, and this meeting, had he been spared, would have reaped the fruit of his labours in the field of Sussex; but, alas! in the midst of his exertions he was cut short in his useful career. Your Council feared that this mournful event would have defeated the object so many had in view; but through the kindness of the Brighton Council, the task of addressing you on the Medical Topography of Sussex has been undertaken by Dr. Mantell—a name too well known to the science of geology to need any commendation here.

Your Council have likewise corresponded with the Manchester Council, respecting a Report on the Medical Topography of that district, to be presented at the Anniversary Meeting in 1852. They have also held communication with Dr. Barham, of Truro, respecting a plan whereby it is proposed to effect a systematic prosecution of the study of Medical Topography,—an object which must be admitted to be deserving of all the assistance which it is in the power of the Members of this Association to afford.

Parochial Medical Relief.

Endeavours are still being made to place on a better footing the system of Poor-law Medical attendance; but your Council cannot on the present occasion announce any decided amendment in this respect.

Sale of Arsenic Bill.

It will be in the recollection of many of the Members, that the manifest evils resulting from the sale of Arsenic were discussed at our two last Anniversaries, and petitions were presented to Parliament, and memorials to the Secretary of State were agreed upon. Your Council are much pleased to state that a Bill, principally founded on the petition presented by this Association, has passed both Houses of Parliament, and received the Royal assent. It is true that the bill does not contain all that was desired, but the Legislature has affirmed that the indiscriminate sale of Arsenic facilitates the commission of crime; and the statute enacts that the particulars of every sale of arsenic are to be entered in a book. No arsenic is to be sold to any person unknown, unless in the presence of a witness, and never except to persons of full age; and it is to be coloured whenever sold in smaller quantities than ten pounds weight. It will be admitted that this is an enactment in the right direction, and whatever may be the defects of the law, it cannot fail to produce good results.

Benevolent Fund.

The Benevolent Fund Committee has pursued its steady course of unwearied charity, and notwithstanding difficulties and discouragement from the want of funds, it has not been obliged to send "empty away" any deserving applicant. A Report will be presented.

District Branches.

A new Branch, called the Dorsetshire Branch, has been added to the Association during the past year; and your Council can continue to speak favourably of the influence of these local reunions on the general prosperity of the Association.

Medical Ethics.

The subject of Medical Ethics is very important, and from the commencement of our Institution has attracted more or less attention. A Committee was appointed at Worcester to report on this subject, but has not hitherto done so, partly because of the death of one of the members, and the ill health of another, and partly in consequence of the great difficulty of carrying on any deliberation where differences of opinion exist, by any means except *vivâ voce* communications. Some progress, however, has been made in the work, and a portion of the rules are in type. At the present juncture it is highly desirable that we should give a calm and judicious attention to Medical Ethics; for it is much to be regretted that many regularly educated members of our profession have connected themselves in doctrine and practice with some of the popular delusions of the day. It will be by the judicious consideration of such important matters that the advantages resulting from this Associa-

tion will become more and more apparent. The inflexible adherence to correct principles and upright conduct, will thus continue to be the rallying point of the members of the Association, and they will evince their determination to maintain amongst them a sound philosophy and unblemished honour.

CHARLES HASTINGS,
President of the Council.
JAMES P. SHEPPARD.
Secretary.

Dr. CORMACK: I have very great pleasure in moving the adoption of this Report, upon which I think it quite unnecessary to make any observation. I am sure it must meet with the approval of all present. I may remark that I, for my part, feel particularly gratified by the concluding paragraph in reference to Medical Ethics.

Dr. FORBES WINSLOW had great pleasure in seconding the resolution.

Dr. CRISP (London) begged, as a member and an old advocate for reform, to move an amendment to the Report. He objected to the plan of reform advocated in that Report. At present they were all in the dark, they knew nothing about it, and, therefore, any advance in the proposed direction might prove of infinite injury to the members of the Association. His reasons for the course he pursued were embodied in the amendment itself, which was as follows:—

"That in the opinion of this meeting the plan of Medical Reform reluctantly conceded by the Council of the College of Surgeons, supported by the College of Physicians, and recommended by the majority of the Council of this Association, should not be adopted, for the following reasons:—

"1. Because the fundamental principles of this Association are a *one* portal or faculty for *all*, uniformity of qualifications, and the representative system of Government; principles that cannot be carried out by the proposed Charters of the Colleges of Surgeons and Physicians.

"2. Because the Colleges have always looked to their own interests—the interests of a class—not to the general good of the profession, as shown by their management of grades, their indifference to quackery, illegal practice of many other evils that affect the advancement of the science, the public welfare, and the good of the profession.

"3. Because the reform advocated by the Council of the Association is not approved of by the majority of the members at large, nor by the generality of the profession in the United Kingdom.

"4. Because the system of grade enforced by the Colleges of Surgeons and Physicians, and sanctioned and supported by the Council, cannot improve the *status* of the general practitioner, who, in the Parliamentary evidence of the President of the College of Physicians, is said 'to treat medical and surgical cases to a certain extent,' who is denied by a late President of the College of Surgeons (Mr. J. H. Green) the rank of a professional man, and who is represented by the Council of this College, in their memorial to Sir G. Grey, July, 1850, '*to have been immemorially designated an apothecary.*'

"5. Because on examination of the qualifications of members of the Council of this Association it is clearly shown that the vast majority of these gentlemen have a direct interest in supporting the proposed charters of the Colleges of Physicians and Surgeons.

"6. Because no plan of Medical Reform short of a Faculty of Medicine in each of the three kingdoms—when all will be properly represented in their respective Universities, Colleges, and Halls—can be durable and permanent."

The PRESIDENT inquired if that motion was seconded?

Mr. STEDMAN (Guildford) felt so much that the general practitioner had not been sufficiently cared for, that though not fully agreeing with Dr. Crisp, and not being fully prepared to second his proposition, he still thought it due to him and the general practitioner, that much of it should be considered by the Council of this Association, therefore he would second it, but he hoped it would be matter for future discussion.

The amendment was put and lost by a large majority.

The reading of the Financial Statement was the next business.

Sir CHARLES HASTINGS said,—the general account of the receipts and expenditure had been already given in the Report, but a more detailed one was expected and would be read. The accounts of the last year had not yet received the sanction of the auditors, and the subject was talked over last night, and it was thought necessary that a Committee should be appointed, consisting of Dr. Horner, Dr. Robertson, Mr. Soden, Mr. Bree, and Mr. Bartrum, to inquire into the financial affairs of the Association, and report thereon before the termination of the meeting. He moved the appointment of such committee.

Dr. RANKING seconded the motion.—Carried.

Mr. CROMPTON observed that the accounts had not been passed for the last two years.

Dr. ROBERTSON (Northampton) had had a resolution put into his hands to this effect, "That the thanks of this meeting be given to Dr. Horner, the retiring President, and that his name be placed (as a matter of course) on the list of Vice-Presidents." Those, who, like himself, had the pleasure of attending the meeting last year, would agree with him, that on no occasion was the chair ever filled by any person with greater dignity, ability, or urbanity. His address was a particularly able and interesting one, and was listened to with general pleasure and satisfaction. He should not trouble them with any further observations, but he was sure the motion would be carried with acclamation.

Mr. WILLIAMS (York) seconded the resolution.

The President said it was scarcely necessary for him to put the resolution, he was sure of the spirit with which it would be carried.

Motion carried.

Dr. HORNER would just in one word return his thanks to the meeting, and especially to Dr. Robertson, for the very kind notice bestowed on him; he would not consume the time which was too valuable to be monopolized by observations of his.

Mr. BOTTOMLEY (Croydon) moved "That the thanks of the meeting be given to the Council, to whom they were indebted for their many services during the year,

and that they be requested to continue them; and that the names of the following gentlemen be added:—

John Muriel, Esq., Ely;
Edwin Morris, M.D., Spalding;
Charles Cotton, Esq., Lynn Regis.

He was sure they were much indebted to them for their labours, which had been performed with so much satisfaction to the Association.

Mr. Smith (Southam) seconded the motion.

The President was sure that motion would be warmly received. The labours of the Council were very great; what they got through was enormous. Motion carried.

Dr. Horner, of Hull, moved that the following gentlemen be appointed Honorary Corresponding Members of the Association:—Dr. Pincoff, of Dresden, late of Manchester, and Dr. Goldie, of Rome, late of York. These gentlemen were very well known. He would propose in addition Mons. Phalari, of Paris.

The motion was seconded by Mr. Newnham, and carried.

Publications of the Association.

Sir Charles Hastings then said,—at the last Anniversary Meeting of the Association, Drs. Robertson, Conolly, Lyon, Mr. Soden, and myself, were appointed a Committe to consider what alterations, if any, could be advantageously made in reference to the publications of the Asssociation. The following is our report, which has received the sanction of all the members. I should say that the consent of the Council was given last night.

Report of the Publications' Committee.

The Committee appointed at the last Anniversary Meeting to consider whether any, and what, improvements can be made in the publications of the Association, have not thought it necessary to make any report until the present meeting. By this means the Committee have had time for mature deliberation, and further experience of the working of the present plan of the publications has been obtained.

It appears to your Committee, that the plan adopted at the Norwich Meeting in 1846 should still be the basis of our publications: that is, the *Journal* should be published once a fortnight, and a volume of *Transactions* annually, biennially, or triennially, according to the accumulation of important Papers, and the discretion of the Central Council at Worcester. The Committee think that the experience of the last five years has shewn that this system will, on the whole, give most satisfaction to the members of the Association.

The conjoint Editorship does not appear to your Committee to have been fraught with any inconvenience. Upon the well known principle of a division of labour, the *Journal* is likely to be better edited when there are two Editors; the one more particularly charged with the foreign department, and the other with our indigenous medical literature.

Your Committee think the Reviews in the *Journal* should be analytical rather than critical. Acrimonious reviews, like acrimonious correspondence, should be excluded. The fittest condemnation to pass upon a work calling for severity of criticism is—not to notice it at all.

The Committee do not recommend the suppression of the Editorial or leading articles. They are always looked for with interest, and, provided the topics are selected so as to steer clear of controversy, are read with pleasure. Your Committee wish particularly to point to medico-legal and medico-ethical questions as occasionally fit subjects for discussion by the Editors. But in the absence of any prominent topic, the Editors need never be at any loss if they will give a brief synoptical view of the medical occurrences of the day; of the cases of special interest that may have appeared in cotemporary journals; of the medical matters, the subject of immediate discussion in London or elsewhere; and of the best reviews that appear from time to time in the Quarterly Journals of Medicine. Interesting articles might be written under the title of "Reviews reviewed." If this should seem too ambitious a title, our Editors might at least call attention to the best written articles in the Reviews as they successively appear. For such as cannot read all the Reviews this kind of help would be very beneficial, as they would then never overlook anything of very decided and superior merit.

The *Journal* has been so well edited for months past, that to a great extent it fulfils what your Committee have been endeavouring to set forth. They think, therefore, there is no cause for complaint, and that the Association should not by undue intermeddling, interfere with the wholesome free agency of the Editors, now that it is so laudably and efficiently directed. At the same time the Committee think it well to take this opportunity to put before the Editors their views as to the scope of their labours, and as to what your Committee think is most likely to satisfy the majority of the Association.

It has been suggested to your Committee, that it would be desirable to appoint individuals or Sub-Committees in the large towns, with a view to collect matter for the *Journal*. The plan, your Committee believe would not work well. We must leave voluntary contributions as heretofore, to the zeal and ability of individual members. It cannot, however, be too strongly impressed on the minds of members, whether resident in towns or rural districts; that whatever diligence and ability may be shown by the Editors in conducting the *Journal*, much of its success must depend upon the assistance they derive from the members of the Association.

Your Committee have given consideration to the question of adjudicating prizes for the best contributions to the *Journal*: they recommend the prizes to be confined to Hospital Reports. Industry might be stimulated and emulation excited by inviting Hospital Reports from the House-Surgeons, or even the Senior Pupils, of our Provincial Hospitals, for publication in the *Journal;* and prizes might be proposed yearly for the best and next best series of Reports published during the year. The Council Fund might, with the consent of the Council, be appropriated to this purpose.

Your Committee would suggest to the Editors whether the reports of the meetings and minor articles of intelligence may not be printed in a smaller type.

Your Committee having said what they think

desirable on the general management of the pulications, beg also to report that they have considered the letter addressed by the President and Secretary of the South-Eastern Branch of the Association to the President of the Council, approving of the general management of the *Journal*, but conveying a censure upon the Editors for a want of candour and fairness in their remarks upon Medical Reform; a subject on which, although there is an agreement on three great cardinal points amongst the members of the Association, yet in detail a difference of opinion exists.

The Committee think that the remarks they have previously made are fully applicable to this case, and they have observed with pleasure for some months past, that the Editors have abstained from controversial writing on these points, and they therefore trust that the members of the South Eastern Branch will feel satisfied that their representations have not been unheeded.

C. Hastings,
A. Robertson,
John Conolly,
E. Lyon,
J. S. Soden.

Dr. Lyon observed that he had dissented in a most material point from this report; but that had since been modified, and he wished to say that he now entirely concurred in the report as read.

Mr. Workman proposed that the report be received and acted upon.

Dr. Conolly seconded.

Mr. Bree believed it was not usual to make objections to the Reports presented at the annual meeting; at the same time, though he did not object to anything in the Report, he hoped he might be permitted to make a suggestion. In the Report of the Committee at the meeting subsequent to the Norwich meeting, held, he believed, at Northampton—("at Derby," was suggested,) at Derby, it was so—a suggestion was made by a very valuable member of this Association, and he (the speaker) did not take any credit for the wording of it in the Report, for it was almost copied from the letter in which it was conveyed by the suggestor, Dr. W. Budd, of Bristol. The suggestion was, "that a prize should be given out of the funds of the Association, which he contended were available for that purpose, an annual prize of not less than £50 for the best treatise on any medical subject which had received the investigation of the writer. He would not specify the nature of the subject, but leave it entirely at the discretion of those who should contend for the prize, and who might thus treat of subjects which they had most closely studied." The suggestion when made by Dr. Budd was, he believed, opposed;—certainly it did not appear in the Report. He did not wish to press the subject now; but he could not resist the opportunity of drawing attention to it.

Sir Charles Hastings observed that the subject had been under discussion, but objections were entertained.

Mr. Bree was aware that scruples were entertained as to its being a proper disposition of the Society's funds, but when they considered that they were 2000 strong, and that their journal was now only published once a fortnight, and that they had only an occasional, instead of an annual volume, surely the funds of the Association should be sufficiently ample to allow of such a prize, one that he believed would raise the character of the Association more than anything that could be suggested, for they should then become the patrons of original investigation in any branch of the science.

The motion was put and carried.

Committee on Irregular Practice.

Dr. Cormack then rose and said, the resolution he held in his hand was one which he considered to be of paramount importance, but he did not consider it necessary to introduce it with a speech upon this occasion. It followed as a corollary to the vote by which the Council's Report had been approved, and an echo of an eloquent passage in the President's Address to which they had listened with so much pleasure and instruction. All he wished was, to bring forward the resolution in general terms, reserving to himself the right of defending or explaining it, in case of opposition, though he hoped the matter would not be gone into to-day, as it would interrupt the order of procedure. The prevalence of illegal practices ought to form one subject for consideration at these annual meetings of the Association, and his motion simply went to this effect, that a Committee of three be appointed to report to-morrow on the course proper to be adopted in reference to that matter.

Dr. Ranking rose with great pleasure to second that resolution, and quite concurred in the desirability of taking the discussion to-morrow when the Committee reported.

A Committee consisting of Drs. Cormack, Tunstall, and Ranking, was then appointed.

The Address in Surgery.

Mr. B. Vallance, of Brighton, proceeded to read the "Address on Surgery." On its conclusion

Mr. Norman (Bath) said he was sure that every gentleman present would agree with him that Mr. Vallance had shown great judgment in selecting the important topics treated of in his paper for their consideration; and he moved that the cordial thanks of this meeting be given to Mr. Vallance, with a request that he would allow the paper to be printed.

Mr. Carden (Worcester) seconded the motion.

The President was sure Mr. Vallance had shown a great deal of judgment in his selection of surgical cases; and the zeal and research he had displayed throughout could not but gain for him the thanks of the meeting.

The motion was carried with much applause.

Mr. Vallance begged to return thanks, in the first place, for the kind hearing they had given him, and in the next for the compliment they were pleased to bestow on his labours. He assured them that but for the

indifferent state of his health, he would have rendered his paper more worthy their attention.

The meeting was then adjourned for an hour.

SECOND GENERAL MEETING.

The Association re-assembled at the same place at two P.M., when

Sir CHARLES HASTINGS begged permission to read a letter he had received from Dr. Babington, the mere mention of whose name would, he was sure, command attention to whatever communication he might have to make; and this letter he was the more induced to read because one of the first objects to which this Association directed its attention was the nature of epidemics, (and it was the first Society that did so), and Dr. Babington was the President of the Epidemiological Society. The letter was as follows:—

"31, George Street, Hanover Square,
July 16, 1851.

"My dear Sir,—Will you do me the favour to comply with the joint request of the Council of the Epidemiological Society and myself, by bringing the objects and proceedings of the Society to the notice of the Provincial Medical and Surgical Association, at their approaching meeting at Brighton. As you are one of our Vice-Presidents, and have kindly attended more than one of the meetings of our Council, I need not enter into any details further than to enclose you our printed laws, our objects, as set forth in an address to the medical profession and the public, and a paper of questions which have been circulated by the Committee formed for investigating the important facts connected with small-pox and vaccination. These papers will give a notion of what we purpose to accomplish; and if you think proper you can present them to the Association. I may mention that we have at present two other Committees actively employed, the one in investigating the epidemic diseases which prevail occasionally in hospitals and other public institutions, such as erysipelas, gangrene, &c., the other in making inquiries respecting the influence which common lodging-houses have in promoting the spread of epidemics. You will have perceived by the public journals that several of the Insurance Offices have afforded us pecuniary aid. Perhaps the Association may deem our objects worthy of support of this kind. At any rate, some of its members may feel disposed to join us; and we trust to your able advocacy for bringing about this desirable end. "Believe me, my dear Sir,

"Yours, very truly,
"B. G. BABINGTON.

"To Sir Charles Hastings, M.D.,
"President of the Council of the Provincial Medical and Surgical Association, &c. &c."

He thought the President and the members would admit that the Epidemiological Society was established on principles which rendered it highly deserving of support, and no doubt those who could support it would be inclined to do so. He was afraid that they could not afford to make any pecuniary grant; but if their finances ever arrived at a state to warrant it, he, for one, should be most happy to advocate such a step. He moved that the letter and papers form part of the proceedings of this meeting.

The proposition was assented to.

INCOME-TAX COMMITTEE.

Dr. SMITH (Cheltenham) said the subject he wished to bring before the attention of the members of the Association was one of very great importance at the present time, and which, he was sure every professional man would agree with him in saying, demanded at their hands the most serious consideration, namely, the taxation imposed upon the medical profession. (Hear.) For a long time the members of the profession had suffered, most iniquitously in his opinion, from that ill-advised measure the income-tax. (Hear.) To the medical man more especially the income-tax had been oppressive, and oftentimes had very seriously affected his future interests; and it had been in its operations most unjust, if not something more, and, as an iustance, he would state a fact. A medical man was taken ill shortly after making a return, which was made at a moment when he was in perfect health. He (Dr. Smith) was not now going into a newspaper narrative, but was stating a particular case. The person was taken ill shortly after making a *bonâ fide* return of his previous year's receipts,—perhaps he had compounded for three years; he was suddenly laid on a bed of sickness, and for some time deprived of the means of making up his income, and yet he had no appeal, and could not prevent the tax collector's receiving that full amount of income derived by Government from the income-tax. The money was not in that case derived from the labours of the medical man; and such an unjust tax ought to be done away with. The matter had been before Government, and the farmer had been allowed to make a claim, and a deduction had been granted to him; but the professional man, stretched upon a bed of sickness, had no appeal. (Applause.) It was a matter which ought to be pressed upon the Chancellor of the Exchequer. For his own part, he was most strenuously and decidedly opposed to the income-tax in any way whatever. It was a most iniquitous and unjust tax; and of all the taxes relative to the medical profession, the income-tax was the most unjust. And with regard to the mode of assessment, it was subject to much abuse. All the clerks were sworn to secrecy; but who would be answerable that a young man of 18 or 19, would, upon leaving his employer, still value and adhere to the oath which he had first taken. He did not say that those young men did break their oaths, but still there was a probability that they might. And as regarded the secrecy of the income-tax, it was almost a complete farce. He (Dr. Smith) had compounded under the impression that his income would be kept perfectly secret. He went before the authorities, and, instead of taking his word, they put his name down at £20 instead of about £7 a year, and he allowed it to remain. He went to pay the money, and in that room where everything ought to have been profoundly secret, he saw some twenty persons, and there was a list there containing the names of all the parties who had compounded under what was called the Special Commissioners' Act, and he could have read the whole of that list if he had thought

proper to do so. That was considered secrecy. So far as professional men were concerned, it was a matter of great importance that the amount of income derived from their business should not be known. He was not satisfied also with the workings of a measure which compelled the medical men of Great Britain to pay a tax from which their brethren in Ireland were exempt. If the medical profession were free in one part of Her Majesty's dominions, it ought to be free in another. (Applause.) And also, as regarded the assessment-tax, their brethren on the other side of the water were exempt, whilst they had to pay, and on these grounds a favourable opportunity existed for the medical profession to bestir itself, and endeavour to influence the Legislature to make a reduction of those taxes which so seriously affected every member of the profession. And with regard to the assessed taxes, there was a movement on foot at the present time, to make the tax upon coach horses more equalized. He knew several parties who were independent, and could ride in their carriage without having to pay that tax, whilst they (the profession) worked hard and laboriously to earn their bread, and yet were compelled to pay that tax. The farmer could now have his horses exempt, but medical men had not the slightest exemption, and Government always imposed taxes upon the profession whatever the effect of the imposition might be. And again, with regard to the house duty, they had to pay 9d. in the pound as professional gentlemen, whilst the merchant, rolling in wealth, had only to pay 6d. He hoped that the meeting would carry his motion and appoint a Committee to inquire into the laws affecting taxation, and more especially with reference to the income-tax. He would have the greatest pleasure in co-operating with any committee which might be appointed. He moved,—"That a Committee be formed for the purpose of investigating the subject of taxation, so injuriously and oppressively affecting the medical profession."

Sir C. Hastings: Will you act as Secretary?

Dr. Smith: I shall be happy to do anything I can.

Mr. Newnham, of Farnham, seconded the motion.

Dr. Malden, of Worcester, said he was sure that all were much obliged to Dr. Smith for bringing the subject forward, and he would render his proposal more complete, if, in naming his Committee, he gave the names of those gentlemen who would be able to attend the Committee's meetings. (Hear.) In this Society there were gentlemen who lived at very remote distances, and if such were appointed they would necessarily be very slow in their work; but if Dr. Smith had any friends belonging to the medical profession residing in the same neighbourhood with himself, and who would cordially co-operate with him and regularly attend the meetings, it would much facilitate the business of the Committee. (Hear.)

Dr. Smith mentioned the names of Mr. Fowler and Dr. Cannon, of Cheltenham.

The names of the following gentlemen were then added to the resolution as a Committee:—Dr. Smith, Dr. Malden, Mr. Fowler, Dr. Cannon, Mr. Colthurst, and Mr. Lowe.

Mr. Lowe said, in order to give some additional impulse to the matter, which he was very glad had been brought forward, he would state a circumstance which occurred to himself at the time when this oppressive tax was first imposed. After about fourteen years' hard practice in his profession, some time between the years 1841 and 1842, his health gave way, and he felt it necessary for a time to give up practice. He was away two years, a portion of one of which was spent in Spain. Whilst there he received official papers having relation to his income for what was called the current year, but which he thought was the previous year. Upon his return from Spain he paid the money due, and found his practice and income, as other medical men had found theirs, after a long absence—ruined. The money claimed by Government was paid into the Exchequer, and he applied again and again to have it refunded; but, although he received promises, the money was never returned to him. There was £15 or £18 lost, independent of the annoyance of having his affairs exposed to the public, and the harshness with which the measure was carried out. It was quite manifest from this that Government was not supposed to give countenance to medical men's wants and requirements; but he thought that if a more just system of taxing medical men were resorted to, and countenance given to them equal to others, they would not require so much aid as had been already shown many members of the profession were receiving. They could not too strongly impress upon the public that expression—"God helps those who help themselves." Feeling the sobriety and propriety of the measure now proposed, he was glad that he had an opportunity o supporting it.

The motion was then put by the President, and carried unanimously.

Financial Statement.

Dr. Horner then read the following Report of the Committee on the Finances of the Association:—

"We, the undersigned, being a Committee appointed by the General Meeting of the Provincial Medical and Surgical Association, report to the meeting, that with the assistance of Sir Charles Hastings, the Treasurer, and Mr. Crompton and Mr. Hatton, the Auditors appointed at the meeting of 1850, we have carefully gone through the Accounts of the Association; and that we find the statements laid before us as under are perfectly correct, and we think the Association is under a debt of obligation to Sir C. Hastings for the time and trouble he has devoted to the pecuniary affairs of the Society.

"We find that the balance in favour of the Association in 1849 was £16 2s. 6d.; in 1850, £109 18s. 6d.; and that the cash balance in favour of the Association up to the 31st July, 1851, is £94 3s. 1½d.; and that it has been reported to us by the Treasurer that the subscriptions due up to this period are £1050.

"F. R. Horner, Chairman.
A. Robertson,
John S. Soden,
C. R. Bree,
John S. Bartrum."

On the motion of Mr. Parker seconded by Mr. Newnham, the report was approved.

Benevolent Fund.

Mr. Newnham read the Report of the Benevolent Fund, which will be published in our next number, together with the cash account, as follows:—

Donation Fund.

Dr.

Amount invested to July, 1850 ...	£2179	10	6
Interest for the year	62	10	0
Donations for the year	188	15	6
	2450	15	6
Per contra	2480	14	6
Balance due to Treasurer ...	29	19	0

Cr.

Amount previously invested	£2179	10	6
Balance due to Treasurer, July 1, 1850	11	9	6
Annuities, November, 1850	37	10	0
Do. May, 1851	37	10	0
Purchase of Bank Stock, July, 1851	214	14	6
	2480	14	6

Value of Bank Stock invested £1200 at 214: £2568.

Subscription Fund.

Dr.

Balance, July 1, 1850	£33	1	1
Subscriptions to June 30, 1851	540	1	4
	673	2	5
Per contra	516	15	0
Balance in Treasurer's hands ...	56	7	5

Cr.

Benevolent aid to June 30	£464	2	6
Nichols, for stationery and printing	20	16	6
Envelopes and stamps	26	15	10
Advertisements and expenses of local Secretaries	5	0	2
	516	15	0

Distribution of Balance.

Donation Fund due to Treasurer ...	£29	19	0
Subscription Fund in Treasurer's hands	56	7	5

Mr. Newnham: This balance existed on the 1st of July; but there has been voted another £35, and when thus reduced, the balance is about £20, and we have a list of claimants for the next Committee meeting, at the end of this month, which will more than absorb all our balance, so that we are not in a very prosperous, though a solvent, condition.

Dr. W. Conolly said,—in rising to move the adoption of the report just read, he could not help congratulating the friends and subscribers on the steady progress—the slow but steady progress—of the Association. There were some circumstances in relation to it peculiar to the past year. It was only during that year that they had held their meetings in London. Hitherto the Committee was at Cheltenham, which place was far less advantageously situated for the administration of the affairs of the Society. And here he would gladly bear testimony to the admirable manner in which the London Committee had been attended. Since the last meeting at Hull there had been fourteen meetings, thirteen, he believed, within the current year, and there had been a tolerably numerous attendance on each occasion, and a vast deal of zeal and assiduity had been displayed. He must also mention that many gentlemen, not members of the Association, but London practitioners, had been very regular in their attendance, and had rendered great assistance. (Hear.) Another event of the past year called for notice. It was at the last meeting that the Secretary and Treasurers of the Benevolent Fund were able to announce that the funds had reached that amount which would justify them in granting annuities; and it was in September or October that they granted annuities for the first time to objects, he believed, of the most deserving character. One circumstance he could not help mentioning, namely, that this was a purely benevolent and purely charitable fund. In this respect it differed from all others with which he was acquainted. He knew of no Society that do not confine their relief to the members and subscribers; but in this case it was different. It was sufficient that an applicant should be a regularly educated medical man, of good moral character, and that himself or family were in distressed circumstances, to entitle him to relief from the fund. The motion in his hand did not confine itself entirely to the reception of the report; it also named their Honorary Secretary. It would be superfluous for him to say one word about him. (Hear.) They were all so well acquainted with his labours—with the zeal he had displayed, and the success which had attended his exertions, that any word of comment was rendered unnecessary. He was sure he should have the concurrence of every gentleman present when he proposed "That the report be adopted; and that the cordial and heartfelt thanks of this Association are pre-eminently due and are hereby given to Mr. Newnham for his great exertions in promoting the interest and increasing the amount of the Benevolent Fund; and that he be requested to continue his services as Honorary Secretary."

Dr. Thompson (Stratford) had great pleasure in seconding the resolution, and in bearing testimony to the assiduity and self-sacrifice of their worthy Secretary, and he had equal pleasure in seconding the request that he continue his services as Honorary Secretary. In the whole range of the Association not another gentleman would be found who would devote so large a portion of his time to the promoting the objects of the Benevolent Fund, as their respected friend, Mr. Newnham. (Applause.)

Mr. Bottomley (Croydon) was a great advocate of benevolent associations. He belonged to one called the Surrey Benevolent Medical Society, established since 1812. He had subscribed to it for many years, and was now a life member of it. They had upwards of £8000, and there were other institutions on the same footing, and it might be presumed, if he did not make the fact known, that the funds of this Association ought to be much larger. He wished gentlemen to understand that there were other institutions, which lessened the amount of the Medical Association Benevo-

lent Fund, and if gentlemen were to subscribe more generally to associations of this kind, which exist in almost every county, there would not be so much distress in the medical profession. (Hear.) Every credit was due to Mr. Newnham for his anxiety and zeal in endeavouring to promote the objects of the Benevolent Fund attached to this Association. He thought that gentlemen ought to be informed of these facts.

The PRESIDENT, in putting the motion, said he was sure it would be quite unnecessary for him to say anything in support of it, as every gentleman in the Association must be well aware of the exertions which Mr. Newnham had made in this particular branch. (Hear, hear.)

The motion was then put and carried with acclamation.

Mr. NEWNHAM having thanked his friends for the very kind manner in which they had acknowledged his services for the past year, could only say that such kindness gave him an additional stimulus in carrying out those exertions for the future, and, while he felt that the shadows of evening were lengthening around him he would endeavour to use increased exertions in doing all that he could to extend the influence and efficiency of the Benevolent Fund. (Applause.) It only happened once in the year that he could have the opportunity of mentioning some facts with regard to the fund, which it was impossible to embody in the report; he should therefore state them now, and in doing so he should refer to certain documents. The speaker then read a letter addressed from Mr. Propert to Mr. Walsh, (secretary to the Widows' and Orphans',) in which he states that he knows of no society which did not require a membership before any application can be entertained, except Mr. Newnham's charity, and he, therefore, advises an applicant to make her case known to the latter. This, continued the speaker, was in itself an answer to Mr. Bottomley's observations. That gentleman had said that he belonged to another benevolent society, and he wished he could make Mr. Bottomley understand the difference between that and their own. He was himself an honorary member of the Surrey Society, and would support it, knowing its object to be good; but it had only twenty members, and what were they as a provident society in the extensive county of Surrey, which, although not large, was, in the upper portion of it, densely populated, and consequently contained a great number of medical men? But it must be also remembered that that was a provident institution. An individual says, "I will lay out a certain portion of my income to receive a greater amount under certain circumstances." And no doubt it was incumbent upon all to provide against emergencies, but still they were not to forget their brethren who were reduced to a state of distress without having had the means of so providing for themselves. (Hear, hear.) The great object was to make a distinction between the two sorts of institutions. Mr. Newnham here read several letters showing that relief (stating the amount and the circumstances under which it was given) had been rendered to certain parties whose names were read, and the gratitude with which it had been received. He had mentioned in the report the fact that, annuities had been granted; they were given to one aged physician, one aged widow, and two other widows with large families; and the amount of comfort which had been derived from them had been very great. (Hear.) He would now mention the fact that such another society as this existed in Ireland, and he must say that when he looked over the report of that Society, he blushed to see that their own efforts were not equal to those of their cotemporary. In respect of that institution, he saw that there were a number of large grants; donations to the extent of some hundreds of pounds; and no doubt the meeting was aware of the large sum left by Dr. Carmichael, which had not got into their hands at present. A large amount of those funds were legacies, and they could not be expected at once, unless they wished their friends to die, and he was sure they did not wish that, but on the contrary, they wished them to live as long as possible. (Hear.) He would now offer one remark with respect to the non-professional subscribers. It occurred to him that a great amount of good might be done in that way if properly set about. Amongst his own personal friends, non-professional gentlemen, twenty guineas had been contributed. He had to-day received from non-professional friends a contribution transmitted through Dr. Jenks, and if the Society only kept this in view, they would find it a very considerable source of revenue. (Hear.) During the last few months a gentleman had made an appeal to the Poor-Law Officers, and that had produced a considerable amonnt. Mr. Cartwright had also got a Committee appointed to consider and aid the Benevolent Fund, and another gentleman had sent him (the speaker) a guinea as a fee for life insurance. Another gentleman had sent a considerable sum arising from what he had taken in midwifery cases he had been called on to attend. These were bright spots which served to cheer his somewhat darkened way, and he now certainly began to feel and hope that a greater amount of interest had been excited in reference to their Benevolent Fund. (Applause.)

COMMUNICATIONS.

Dr. MALDEN (Worcester) said,—owing to the courtesy of the Council, the selection of the subject for my paper was left to myself, therefore I thought that I had better select a stirring one, and I have selected "Empiricism." But as in what I have to say to you I am not to occupy more than half an hour, I must endeavour to do the best I can with it, and if I tire you out in half an hour, I shall be vastly astonished. (Applause.)

The paper was received with applause, and will be published hereafter.

Dr. CONOLLY then read a valuable paper on the "Prognosis of Insanity."

The meeting then adjourned.

At six o'clock the members again assembled at the Pavilion, in compliance with the invitation of Dr. Jenks and the other medical gentlemen of Brighton, and partook of a splendid cold collation which awaited them.

Dr. Mantell's Address.

After dinner Dr. Mantell delivered a lecture upon "The Medical Topography of Sussex," of which the following is an outline:—"When Washington Irving returned to his native country, after having acquired a European reputation, and was received by his countrymen with warm congratulations, he observed, that he who goes abroad in the world and reaps a full harvest of worldly favour, will find no applause so sweet to the soul as that which awaits him in his native province. That feeling was most fully impressed on the lecturer's mind on this occasion, while he was expressing his gratitude to the committee for having thought of him while he was absent from Brighton, and given him the privilege and pleasure of addressing his medical friends in it. In the good old times, when there were but four elements, earth, air, fire and water, there would have been but little difficulty about a lecture on medical topography; but now, when we are surrounded by a thousand occult influences, those least obvious to our senses producing the greatest effects on the human constitution, for, as his friend Faraday had said, the most important operations of nature, are the most imperceptible—the action of causes which we cannot well appreciate—it was quite different. We all knew that changes from heat to cold, drought to moisture, will produce influences in the human constitution, and the general effects of such changes are well known, but circumstances are continually arising to baffle all attempts to explain the phenomena that arise in reference to such physical conditions. Now, the superficial soil produces the most visible effects on the constitution, yet the influences promoting the greatest effect have a deep hidden source. It would be his object to point out the geological character of the country and the superficial detritus which covers the surface, and which might be supposed to influence objects upon it, as well as to offer general observations which might seem to bear on the matter which was the immediate object of their inquiry. He proceeded to a geological survey of this part of the country. Beginning at London, he showed that the metropolis was geologically situated over a basin exactly similar to that of Paris, under which the water from the surrounding country flowed, and that London was as favourably placed for the formation of an artesian well as Grenville, near Paris, where a magnificent example existed of the triumphs of geological knowledge, the fact that water would be obtained by boring not only being predicted, but also the temperature at which it would be received when spouting from the bowels of the earth into the air. Geologically journeying to Brighton, the Doctor showed that after meeting the red sand formation, we arrived at the chalk of Merstham, after which we came again to the red sand formation extremely impervious to water, first, there being a stiff argillaceous clay, often requiring six horses instead of two to draw the plough through it, and then Red Hill, so called from the ferruginous colour of the clay there. Leith Hill, Surrey, seen looking westward, was in this range. Next we met with the Wealden formation. Up to the Balcombe range of hills, the strata all dipped towards London. Journeying still southward we met, only the dip was in the opposite direction, a repetition, in an inverse direction, all of these strata, the last being the chalk, and ending in Brighton. But beyond the chalk at Brighton occurred the stratum which he had called the elephant bed, bones of the elephant, hippopotamus, horse, and other animals, being found there. This succession of strata extended in both directions. The chalk appeared at Hertford, Merstham, Brighton, Dieppe (across the Channel), and near Paris on this side, and again beyond; and at Beauvois, the Wealden formation was visible with beds of Sussex marble composed of fresh-water shells. Doubtless, the chalk once covered the entire surface; and the present condition of the surface, arose from upheavings in one place being accompanied by depression and displacements in others. Years ago, the Wealden was regarded as an uninteresting salt-water formation; now it possessed great geological interest, and was known to be, he having first suggested the fact, a fresh water formation, being in fact the delta of a mighty river. The Doctor here stopped short, lest he said he should "get into geology" (laughter), and then he went into geology again. Beyond Kemp Town, just above the beach, there was a little terrace of chalk; but upon this there was a layer of beach, the elephant bed, containing granite and other boulders, bones of animals, &c., evidently brought from distant countries by icebergs, which on arriving in a warmer climate melted, and deposited the burden which had been frozen in their masses, everything, as would be the case under such circumstances, being in a high state of preservation. "Drift" was now the term applied to these ice-borne materials, which were formally called "Diluvium," from a notion that they were caused by Noah's Deluge—a mode of covering ignorance analogous to that resorted to in days gone by, when every disease unknown to the faculty was denominated "nervous." The Doctor proceeded to express an opinion that ague, typhus fever, &c., depended not altogether on dampness, but upon something generated in a locality. Years ago he was surgeon at Ringmer and the surrounding parishes, and so distinctly did he find fevers confined to a district where the blue clay succeeded the chalk, that at his representation, the healthy chalk site of the old barracks was retained by Government for use in the event of another war breaking out. In fact, a geological map, denoting the locality of the blue clay, would denote peculiarly the region of fever. Dr. Mantell then mentioned that ague, typhus, &c., used to prevail on the low grounds contiguous to the river at Lewes, but not on the chalk; and an instance of the periodical attack of fever in the autumn, of a family living on the top of the chalk hill, which was got rid

of by the removal of an accumulation of dung from a large stable. Some cases of cholera in the neighbourhood of a large uncovered sewer at Chelsea, were also mentioned as showing the local origin of disease; as also the theory of a French doctor, whose name we could not catch, who came to England in the last time of cholera, that cholera depended on the galvanic condition of the rocks of the district. He conceived that alternations of sand and clay gave rise to galvanic action; and, with his theory in mind, he traced the progress of the cholera in France and England. He said he had been to the Registrar-General, who told him that "cholera was owing to de poverty of de peple, to de dirt, to de stink;" but, he added, "You have always de poverty, and de dirt, and de stink, but not always the cholera." Both in France aud England they found no cholera on the chalk, except in one place. "*Mais*," said the Frenchman, "*ce n'est pas une exception;*" a great quantity of detritus, brought down by the rivers had been left on the spot. In conclusion, the Doctor suggested that disease might arise from infinitesimal forms of animal life—the cholera from a new creation of animalcules; and with much energy, and we thought with much success, he combatted the assertion that this theory was either a cause or a consequence of the holding of materialist opinions.

At the conclusion of this address the applause was most enthusiastic. A gentleman then rose and expressed a desire to hear the remarks which he presumed the lecturer had intended to indulge in, illustrative of certain diagrams which he had caused to be suspended in the room. The Doctor accordingly consented to enlarge on the topic they suggested, and after a short interval he entertained the audience with an account of the discovery by himself in the weald of the *debris* of the iguanodon, an extinct reptile. In connection with this he introduced much pleasant gossip relative to the reptile world of the past days, drawing especial attention to the pelorosaurus, probably a reptile of eighty or ninety feet in length, one of the bones of which was represented in a diagram before them.

The meeting broke up about ten o'clock.

THIRD GENERAL MEETING.

THURSDAY, AUGUST 14.

THIS morning the members of the Association and friends breakfasted together in the Banqueting Room of the Royal Pavilion, after which they separated to view the Sussex County Hospital, and various subjects of interest in the town. At twelve they re-assembled in the Music Room, when Dr. Jenks again took the chair, and called on Dr. Cormack to bring up the report of the Committee which had been appointed on the previous day "to consider the course which the Association ought to adopt with reference to the prevalence of irregular and unprofessional practices."

Dr. CORMACK said,—I have the honour, Sir, to be commissioned to offer for the acceptance of this great meeting, the Report of your Committee on irregular practice. Although the terms of our appointment might have justified a more general notice of the prevailing delusions and impostures of the day, we have thought it best to direct your attention solely to what is called homœopathy, as, along with it, is almost invariably associated the practice of other systems of charlatanry. I am anxious to state at the outset, that we have not thought it necessary to adopt the language of controversy, and we have endeavoured principally to mark out the necessity of excluding from this Association three classes of practitioners; first, those who really (and many of them honestly) practise homœopathy; second, those of a mixed, or bastard kind, who practise homœopathy in combination with mesmerism, hydropathy, allopathy, or *any pathy* which the patient most may fancy; and, third, those who, under various pretences, hold professional intercourse with homœopathic practitioners. It is not necessary in this assembly to prove that homœopathy is a mere chimera—a system opposed to reason, common sense, and all medical experience; but I may in a few words give you a brief synopsis of what Hahnemannism is. Dr. Cormack then stated that there were three leading doctrines, or rather dogmas, promulgated by the German dreamer:—1st, that all diseases depended upon three inherent taints, the principal one being the itch, or psoric, as he called it; 2nd, that like cures like—*similia similibus curanter;* and, third, the giving of infinitessimal doses. With regard to all of these chimeras, Dr. Cormack averred that they had no scientific basis, no facts to rest upon, and the statements made about medicines acting when divided into the decillioneth of a grain, are so transcendantly nonsensical as to be entertained even as a subject of consideration for an instant, only by an unhealthy mind. The simple fact is this, that Hahnemann's doses cannot be demonstrated to exist, and are so small, that the mind of man can form no conception of their minuteness. Some homœopaths repudiate in a sort of half-and-half way the small doses, but the public who feed homœopaths generally conceive that their medicines are given to them in the attenuations of Hahnemann, in quantities ranging from a millioneth to a decillioneth of a grain. Small doses were lauded at the meeting in Hanover Square Rooms, but these laudations were, perhaps, applauded by men who give more freely than many of us would dare to do, strychnia and aconite, and other such like drugs, the most terrible doses of which are drops and fractions of a grain. Large doses of more common medicines, as I well know, are also every day prescribed by men who come forward as candidates for homœopathic practice among the wealthy and the noble. I have said enough to show you how vain it is to define what is meant by homœopathic practice, when I mention that at a recent meeting of the annual congress of homœopathists, there was present as a large participator in the business, Dr. William Mac Donald, who, besides being a homœopathic practitioner, is a leading man as a believer in, or lecturer on, the highest degrees of mesmerism. Then Dr. Macleod, (whose autobiography I hold in my hand,) the keeper of a water cure inn at Bewrydding, in Yorkshire, is a

chosen champion of homœopathy, a man whom the *Homœopathic Times* delights to honour, and who treats his patients by globules and wet sheets. But besides the legitimate and the bastard homœopaths, there is another class of men who have no right to sit with us as brethren on these benches, nor be associated with us in this Society. Regarding this class, I would wish to say a little; but that little must be plain, and it is this, that we must not—not one member of this Association must hold professional intercourse with those traitorous men who meet at the bed-side with those whose medical creed and character I have, though perhaps too mildly, depicted. A broad line of demarcation must be drawn, and it must be done this day. (Applause.) Private friendships have perhaps made some of us too long in adopting the painful but only right course. To error or imposture there never can be made an honourable exception. After adverting to various other subjects in the report, Dr. Cormack said that he approached the next topic with feelings of the deepest pain and sorrow. He continued:—I will not yield to any man in my respect for the sacred office of the ministry; myself, the son of a Clergyman, I have always felt that the only other calling more noble than our own is that of preaching the everlasting Gospel, but, when Clergymen assail us from the pulpit and injure our influence with our patients by their zeal in converting proselytes to Hahnemann, neither delicacy nor duty exact from us silence. Numerous facts have been laid before your Committee, from which we have ascertained that in some districts of the country the zeal with which the Clergy have taken up homœopathy knows no bounds, and many of our brethren have had their patients wiled away. I would not have ventured however to bring this prominently before you did I not hold in my hand a sermon preached by a Rev. Vice-President of the Hahnemann Hospital, in Bloomsbury Square, from which it is necessary that I should read to you some extracts. The preacher was the Rev. Thomas R. Everest, Rector of Wickwar. He selected his text from the Gospel of St. Matthew:—"And as ye go, preach! saying, the Kingdom of Heaven is at hand. Heal the sick, cleanse the lepers, raise the dead, cast out devils: freely ye have received, freely give"—ch. x., 7 and 8 v.

In this text the reverend gentleman finds revealed the doctrine of Hahnemann, but I will give you his own explanation of the words of the Evangelist "Heal the sick and cleanse the lepers! CLEANSE the LEPERS! Why pick out disease at all from amongst the ills of man? And if so, why that particular one? Why not blindness or madness, the stone or dropsy, rheumatism or the gout?" Thus you see that the leprosy of St. Matthew and the psora of Hahnemann are the same thing. That in fact is the grand idea of the sermon, but the great redemption was not complete, or at least not available, till fallen man—till Hahnemann appeared. I almost feel, Sir, that the passage is too awful to recite before you, but I must do it to save myself from the charge of misrepresentation.

"At the fall of man sin entered into the soul and disorder into the physical frame (with which that soul is connected) at the same moment. God sent his Son to repair the mischief, and He bade His ministers preach the Gospel, and heal the sick;' that is, cure the moral disorder and the physical disorder together; and for 1,900 years that precious wisdom has cried in the streets unheard. The preacher of the Gospel, not aware that that Gospel could never have free course until the physical leprosy of man was cleansed and his chronic tendencies cured, has handed over to a separate profession the business with which his Lord entrusted him. And that profession, unconscious of its privileges, its duties, its powers, has, so to speak, ignored the whole question. It leaves those mad whom it might have cured, or it maddens men by large doses of powerful medicines; and then we wonder at the crimes and folly that mark the career of man. Let us be assured, brethren, that there is in the Gospel of Jesus a life, a power, a spirit, which is so much in harmony with man's happiness and brings with it so much good, that if it had been understood by those who teach it and had had fair play, it would long ago have altered the whole face of society. But in spite of Moses, in spite of Jesus, in spite of the law of nature, alike deaf to God's voice and blind to facts, the medical profession has left the leprosy of the flesh to entwine itself with the leprosy of the soul. Between the two, man's tendencies to sin are increased by the disorder of his reason, caused by the abnormal working of his machinery; and the Gospel finds in whom God intended that all should be normal, but with whom it can only communicate by means of nerves in a chronic state of irritation and a brain in discordant working, not a gentle convert but a hardened criminal, a perverse unbeliever, a furious fanatic, or an eccentric, unreasoning lunatic. But old things are passed away, behold all things are new made unto us. Let us now see what the new system proposes to do for the human race." That is to say, let us see what homœopathy can do to complete the Christian system. The next extract which I shall read is an appeal to the pockets.

"Mothers! do you wish to see your children washed clear of that leprous tendency to disease which fills our grave-yards with sweet young flowers, cut off untimely, and which to those who survive, transmits a legacy of pain, sin, and sorrow? THEN AID US!"

"Fathers! do you wish to see your sons grow up faithful Christians, and sensible men, with a normal allowance of health, able to use calmly the reason which God has given to man for his comfort here, far from all extravagance, and all eccentricity, holding a course of life steady, reasonable, religious—such a course as man, healed, God-fearing, and intellectual, should hold? THEN AID US!"

"Governors of God's heritage, monarchs, Parliaments, magistrates! There is a gloomy thunder-cloud collecting on the horizon, rolling its deep masses over the face of day, threatening, lurid, portentous; but no man knows exactly of what. It is called socialism, communism, the rights of man, the rights of labour, the red republic. It is earnest, dark, sombre, avenging. It

has been lashed up by hunger, low wages, glaring inequality, wicked passions of psoric origin, roused by alcohol and medicines, maddened by burning eloquence. It has no strain of gentleness in it. It is arrested by neither ridicule nor menace. There is not one smile, or one jest hidden beneath its fantastic twirls. The sword has cleft it, but it re-unites more baleful. The cannon has poured its hail against it, but it rolls on as dense and as red as ever. The priest has cursed it; soicety trembles to hear of it; but there it hangs, in the calm that precedes the earthquake; baffled, perhaps, but biding its time till the "hour come, and the man." Shall I teach you to draw the lightning quietly from it ere it bursts upon your throne and your altar, and piles all your institutious into one heap? AID US!" I must inflict one more extract upon you. It is the preacher's account of the medicine of love.

"The medicine of love has prepared the soul for the Gospel of love. The seed of the word will soon strike root in such a soil, and bring forth much fruit; not the fruit of thievery and crime, afflicting folly and snarling religion, that exists at present, but a wholesome crop of sensible actions and sound opinions ripened by the steady rays of reason and religion. Growing up thus amidst calm, and sunshine, and love, and harmony, induced by the medicine of harmony, the education of the young candidate for heaven commences. The first care of the parents is, by proper dynamic medicines, (for medicines in a brute, material state, having a totally different action on the human organism, are perfectly useless, or rather merely injurious), to eradicate all those psoric tendencies which cause or increase all our aches, pains, ill tempers, obstinacies, rebellions, cachexies, and all chronic diseases. Life in the beginning does so long for harmony, that if thus gently aided, it soon overrules all discordant tendencies. The molecular attraction proceeds normally. The infant developes into a normal child of the normal type, in whom all tendencies to irregularity, whether of body or mind, growth or disposition, are much weakened and simplified. It has never been exacerbated by frantic doses of powerful medicines, never been excited by poisonous diet, never been beaten into obstinacy, never imitated the quarrels of its elders, never been spoiled into selfishness, never indulged into evil tempers; continuing the physical education, and watching carefully the cries which life utters for assistance, in order to relieve her just where and when she wants aid—never by mere palliatives, but always by dynamic remedies, whose energumenic power, akin to life itself, has been subtilly awakened and called forth from the brute mass in which it lay slumbering, and, if well chosen, will, by its unfailing elective attraction, restore to life at the very spot, by the very nerve wherein it labours, the very FORCE in which it is deficient—you commence the moral and religious training of the child. Plain, simple, easy, and charming, is THE GOOD NEWS OF GREAT JOY."

So much for the medicine of love. Let us now hear what the preacher says of our system of medicine. "There was once a marriage made in Heaven; but you put asunder those whom God joined together in heaven when you separated the healing of the sick from the preaching of the gospel, and made two professions out of that which Jesus made one; and therefore it is that the art of cure separated from the holy principles of love has lost its way, and fallen into foul company, and consorted with all unloveable things—cathartics, moxa, the lancet, emetics and blisters." Now, Sir, this sermon was preached in aid of the Hahnemann Hospital and under the patronage of much of the wealth and aristocracy of this country. Emblazoned on its title page we find the names of his Excellency Chevalier Bunsen, his Grace the Duke of Hamilton, the Earl of Walton, the Earl of Shrewsbury, Lord Robt. Grosvenor, M.P., and many other noblemen and Members of Parliament. To such lists we are generally referred triumphantly, but I would only say that it would not be difficult to add to the list hundreds of names of equal note, comprising noblemen, clergymen, and gentlemen who also support this quackery. But, Sir, I have yet to learn that these men are fit guides for the physician, and I would say that not all the coronets and mitres in England can convert a lie into the truth, and, layman though I be, I hesitate not to proclaim in this public assembly that the sermon from which I have quoted is replete with quackery, heresy, and impious doctrine. (Prolonged applause.) Dr. Cormack then read the following

Report on Irregular Practice.

"Brighton, 14th August, 1851.

"Your Committee have, after consultation with numerous members of the Association, maturely considered the subject referred to them, and beg respectfully to suggest the adoption of the following resolutions:—

"1. That it is the opinion of this Association that homœopathy, as propounded by Hahnemann and practised by his followers, is so utterly opposed to science and common sense, as well as so completely at variance with the experience of the medical profession, that it ought to be in no way or degree practised or countenanced by any regularly educated medical practitioner.

"2. That homœopathic practitioners, through the press, the platform, and the pulpit, have endeavoured to heap contempt upon the practice of medicine and surgery as followed by members of this Association and by the profession at large.

"3. That for these reasons it is derogatory to the honour of members of this Association to hold any kind of professional intercourse with homœopathic practitioners.

"4. That there are three classes of practitioners who ought not to be members of this Association, viz., 1st, real homœopathic practitioners; 2nd, those who practise homœopathy in combination with other systems of treatment; and 3rd, those who, under various pretences, meet in consultation, or hold professional intercourse with, those who practise homœopathy.

"5. That a Committee of seven be appointed to frame laws in accordance with these resolutions, to be submitted to the next annual meeting of the Association.

"6. That the thanks of the Association are eminently due and are hereby given to the Presidents and Fellows of the Royal Colleges of Physicians and Surgeons of

Edinburgh for their determined stand against homœopathic delusions and impostures.

"7. That the thanks of the Association are also due and are hereby given to the Universities of Edinburgh and St. Andrew's, for their resolution to refuse their diplomas to practitioners of homœopathy; but the Association feels imperatively called on to express its disapproval of any school of medicine which retains among its teachers any one who holds homœopathic opinions.

"8. That these resolutions be printed, and transmitted to all the medical licensing bodies and medical schools in the United Kingdom; and that they likewise be inserted in the *Times* newspaper, the *Morning Post*, the *North British Advertiser*, *Saunders's News Letter*, all the British and Irish medical periodicals, and in such other journals as the Council may sanction upon the recommendation of the Branch Associations.

"In proposing these resolutions for the adoption of the Association, your Committee are anxious to state that they are actuated by a strong sense of the importance of the subject in its relation both to humanity and morals. They most conscientiously believe that the countenance afforded to the form of charlatanry herein alluded to is detrimental to the true interests of the public, as it is subversive of that strict integrity which ought to characterize practitioners of medicine, and which has ever distinguished the profession in these kingdoms.

"John Rose Cormack, M.D., Edin., Fellow Royal Coll. Phys. Edin., (Putney).
"James Tunstall, M.D., Edin., (Bath).
"W. H. Ranking, M.D., Cantab., (Norwich).

Such, then, continued Dr. Cormack, is the Report of your Committee; and we now ask you to adopt it as an expression of the sentiments of this Association. Let us say our own mind plainly and calmly. Silence would be far better than the giving forth a feeble and uncertain sound.

(Dr. Cormack resumed his seat amid prolonged cheering.)

Dr. Malden (Worcester) moved that the report be adopted. After what he stated yesterday, this Association could not doubt his sincerity, and it would therefore be needless to detain them by any further comment.

Dr. Williams (London) begged to second the resolution. In doing so he would offer a very few remarks, for as far as he could judge from the demonstration of feeling which had greeted the report, the Association was pretty nearly unanimous on the subject. (Hear, hear.) It might be a question whether it was within the province of a body of this kind to take up and express opinions so decidedly on matters of this kind; but he only asked the meeting if such an Association did not take it up, where could they look for an expression of the voice of the provinces? (Hear, hear.) We found that homœopathy, and various kinds of quackery were rampant in the land; that they were deluding the great, the learned, the powerful, and, worse than all, the poor (hear, hear); that not only were riches placed at the command of these impostors, but what was far more precious and far more terrible to contemplate, the lives of our fellow-creatures. There was at this moment a wholesale traffic in body and soul; for who would say, where persons were hurried to the grave by improper treatment, or by neglected treatment, who would say that there was not a perishing of body and soul together? (Hear.) It was altogether an awful consideration, and he really trembled when he looked back on the number of terrible cases which had come to his knowledge, where, at the eleventh hour, the regular practitioner had been called in, and it was too late;—when the precious time during which medicine might have availed to save life had fled, and there was nought to be done but shake their head and exclaim—"alas! the folly," and, I fear I must add—"alas! the knavery of people, too." Then the question was:—"Who should take the question up?" The College of Physicians at Edinburgh had shown a good example, and he could now wish that the College of Surgeons, and other bodies would follow it. (Hear, hear.) The medical profession should stand forward boldly and determinedly; and if they did not pass laws, let them express their entire disapprobation of such proceedings. The public were continually making this confusion: they said it was only a difference of system,—that the homœopathists had their system, the regular practitioners theirs; that doctors were always differing; that the homœopathic practitioners were doctors as well as the others, and that they were entitled thus to differ. They refused to make the distinction between that which was sanctioned by the experience of ages,—that which was generally received by the whole profession; and any infatuated motion that might be brought up by any designing or fanciful person, and adopted by a number of fashionable lords and ladies, and thus made prevalent in the land. If the College,—if the licensing boards and Colleges did not stir, then was it incumbent on bodies of men, however collected together, to express their opinion definitely and decidedly; and he thought it incumbent on this Association, assembled as they now were, to adopt the report which Dr. Cormack had brought forward, which had been carefully considered, which might undergo further consideration in committee, and then be adopted as the opinion of this Association. (Hear, hear.) One word before he sat down, by way of warning to his professional brethren. They had heard enough to laugh at, to pity, and to ridicule, in the extracts read by Dr. Cormack; but he would really wish that the members of his profession, who had time, would provide themselves with the proper materials for discussion, by making themselves well acquainted with the Hahnemannic doctrines; they would then be more entirely convinced of their absurdity than they could be without being in full possession of the facts. He separated homœopathy, honestly practised, from homœopathy mixed up with hydropathy. In the latter case, it was little more than deceit and swindling, professing one thing and practising another, it was getting into practice by a side-wind, which was disgraceful. It was quite certain that neither the profession, nor the public, were fully acquainted with homœopathic doctrines. If they could only understand the absurdly nonsensical quantities that were given as efficient means of counteraction to diseases,

they would see the utter absurdity of the thing. In the report, in the *Times* of yesterday, of the proceedings of the Homœopathic Association, the reporter made some attempt to throw cold water on homœopathy. He said, by way of ridicule, that some of the ancestors of the good gentlemen present probably took in a dose three times as much medicine as would have doctored all the homœopathic patients in Golden Square. But this fell far short of what homœopathy is; of the real proportion between homœopathic doses and ordinary doses—doses which had been determined by long, careful, and laborious experience, followed out in a scientific manner. The difference between the one and the other was about this: the dose for an individual on the allopathic plan would be enough for 10,000—he was speaking much within limit—would be enough for 10,000 (ten thousand) times all the inhabitants of this globe. These were the absurdities of homœopathy. It was very well to talk of the billionth and trillionth part of a grain. We could not comprehend the words. The human mind could not grasp the ideas; and he would appeal to any chemist or natural philosopher who was in the habit of considering numbers, on the subject. One of the most delicate chemical tests would, he believe, detect the 100,000th part of a grain. Sulphuric acid would detect lead in that extreme proportion; and he believed that a similar assertion was true with regard to chlorine. But the 100,000th part of a grain would have to be diluted twice, that is to a million of times, before it would reach the homœopathic tenuity. And homœopathy taught that when the human body was under disease—under a terrible disease, capable of destroying all the vital functions, that disease was to be counteracted by something a million times less than could be detected by the finest chemical test that was ever discovered! The thing was so preposterous to any one in the habit of considering the minute division of objects, the molecular division of matter, so out of all reason, that it only required to be put a little before the public for the delusion to be seen. He thought, then, that it was the duty of the profession to show that they were determined and decided in the matter. (Hear. One word more relative to one of the resolutions. It had been said again and again that although it was wrong to practise homœopathy, there might be no harm in giving an opinion to the homœopathist as to the cause of disease. That was the way in which the homœopathists built up their edifice. They said they cured such a case and such a case that was declared by Dr. So-and-so to be incurable. In this way many persons had been entrapped. Again and again did instances of this occur; and therefore there must be no compromise. The profession were bound to protect themselves and to protect the public;—(Hear, hear)—and it was due to the dignity of the science of medicine that a decided opinion should be expressed, and resolutions carried with regard to this awful—this increasing heresy. (Loud applause.)

Dr. Crisp went to the full extent with the gentlemen who had drawn up the Report, and he regretted exceedingly that they had not gone farther. He believed they had not gone to the root of the mischief; they had omitted the most important question connected with the subject. In the first place, the Government ought to be blamed for the encouragement which they gave to quackery in every shape. The regular practitioners paid stamps on their diplomas; and some who had taken several degrees had paid £30 or £40 in that way. The same Government, for a trifle, made the medicine of the quack legitimate. We had a President of the College of Surgeons—a professed Mesmerist—selected to deliver the Hunterian Address, and to examine quack medicines; we had Dr. South, in his "Household Surgery," telling the public that each surgeon ought to have an apothecary's shop, the key being kept by a clear-headed person. With regard to the University of Edinburgh, there was a professor of homœopathy there, and no objection was made to his holding the chair. The College of Physicians at Edinburgh had been, by the pressure from without, forced into a different course. As to the propriety of discussing the question of Homœopathy in these meetings, or in any other meetings, he thought they might as well try to bottle a sun-beam or pocket a shadow. It defied reason—it was absurd—it was ridiculous; and, as a member of the Association, he must express doubts as to the propriety of gentlemen corresponding, and publishing the correspondence, with any unprofessional person. If the public chose to adopt this foolish and dangerous system, it was the duty of the regular practitioner to warn his patients against it; but he did not think a professional man consulted his dignity who went beyond the warning. (Hear, hear.) He was not quite satisfied with the terms used by Dr. Williams, who thought a practitioner was justified in meeting a homœopathic practitioner. (Cries of "No," and "He did not say so.")

Dr. Horner: I should be sorry if anything went from such an Association as this, that was not in accordance with the fact. I think I can contradict Dr. Crisp when he states that the University of Edinburgh permits a gentleman to hold a professor's chair, who professes and practises homœopathic doctrines. If I recollect rightly, the College at Edinburgh expelled from that chair a physician, Dr. Henderson. (Cries of "No, no.") I beg pardon, is that not so?

A Voice: They wished to do so.

Dr. Crisp: It is notorious that Dr. Henderson practised homœopathy.

Dr. Horner: I am very sorry for my own alma mater that it is so.

Dr. Cormack said the University had no power to expel. All the power they had, they exercised. He was clinical professor there, and had clinical wards in the infirmary, and they prevented him from teaching. Unfortunately, he still held the chair of pathology; but he had never dared to teach homœopothy from that chair. The College of Physicians and the University, were two distinct bodies. In the College they acted decisively; in the University nothing could be done without the sanction of the patrons. By passing the

resolutions before the meeting, the Association would aid in ridding the University of its present incumbrances.

Dr. COWAN was not quite a new comer in the anti-quackery ranks. He had laboured against the various delusions which had prevailed in medicine, especially those relating to our own noble science; and he must express his gratification that the present opportunity was taken advantage of to make an associated expression of opinion go forth with regard to the increase of homœopathy amongst them. He regarded it with a very grave view; he looked at it as one of the moral phenomena which were rolling over the age. It was not the practice of medicine that was at stake, but the practice of sound thinking. Directly we advanced beyond the practice of admitting for truths only those things which had long occupied the minds of men, and been verified by the experience of ages, and attempted to bring into existence new notions, and new phases of the human mind, and gave them the outward formality of facts, we departed from stability of judgment and soundness of thinking. A homœopathist was a mystic, without sound judgment on any subject; he was to be distrusted in every form of his thoughts; he had lost the ballast of his reasoning faculties, and set at defiance all those means by which the human mind were regulated and directed. We live in an age in which soundness of thinking was most essential; in which moral and intellectual divergencies of every kind were taking place; and the man who looked forward for truth, instead of backwards, was not to be trusted, for his mind might run in every conceivable direction; believing to-morrow what to-day he disbelieved, and reducing all medical practice to confusion. This was not a matter of etiquette, but it was a matter of absolute fundamental truth; because if these things were true, medical men were practising a delusion,—a lie, and the world before them had believed a lie; all wisdom had perished in the world; and now, like a mushroom, now to start into maturity, in this nineteenth century. Features like homœopathy were not isolated. The age in which we lived had a religious feature. There were men who assumed one form of doctrine, while they were pledged to the reverse. In the medical profession, men assumed the titles of those who had been educated in the Universities; they adopted avowedly a dishonest conduct, putting themselves in the irreconcilable position of combatting those whose titles they assumed, at variance with honesty, though apparently consistent with private interest for the moment. They, the public, attacking and subverting a truth by which they had attained their position. No morally-consistent man could hold such a position. Unless the homœopathist could support the diploma he had gained, he ought to leave the profession and stand alone, unassociated with any practice of honest and legitimate profession. The profession ought to feel strongly on this point, and in discussing the question he did not go into it as one in detail. He maintained that it was utterly false, root and branch; utterly beneath the investigation of any honest and scientific man; it was waste of time to dispute as data, that which bade defiance to all experience,—to all physical or metaphysical science. If a man said to him, "two and two make five," he did not speak to that man twice. He felt that that man was gone. (Applause.) And if a homœopathist declared his belief, he and the speaker were apart for ever. The homœopathist admitted things at variance with every conceivable opinion of rational experience; and under these circumstances they must stand aloof. He (the speaker) could not acknowledge, in any form or shape, principles at variance with a respectable and conscientious, and a reasonable profession. (Loud applause.)

Dr. TUNSTALL moved that a report of the proceedings connected with homœopathy should be circulated by the Council at Worcester, among the members of the Association.

Sir C. HASTINGS: Pass the other resolution first.

The PRESIDENT: After the eloquent speeches we have heard on the subject, I think there will be very little disagreement as to the resolution being carried. (Cheers.)

The motion was then carried unanimously.

Dr. CORMACK: One of the resolutions says, a committee shall be appointed to frame laws. Perhaps you will now name the committee.

Sir C. HASTINGS suggested the three gentlemen who drew up the report, with the mover and seconder.

A MEMBER: Some one suggested that Dr. Cowan be added. (Cheers.)

Sir C. HASTINGS: I think we should have power to add to their number.

Dr. TUNSTALL: Then we will add you, if you please, Sir Charles. (Laughter.)

And the Committee was so constituted, consisting of Sir C. Hastings, Dr. Cormack, Dr. Tunstall, Dr. Ranking, Dr. Malden, and Dr. Cowan.

Dr. TUNSTALL then repeated his motion for the immediate publication of the proceedings relative to homœopathy.

Dr. HORNER: I beg to second that; and I do it as a physician who has seen the fatal effects of homœopathy. I have in my own town seen the fatal and distressing effects of it; and I should be glad of such a document to put into the hands of the good folks of Hull.—Carried unanimously.

SALE OF ARSENIC BILL.

Dr. SIBSON read the following report for Dr. Toogood and himself, detailing the successful operations of the Poisons Committee in getting their recommendations with regard to the sale of arsenic, adopted by Lord Carlisle, and since passed into a law.

Report of Arsenic Committee.

Dr. Toogood and Dr. Sibson, two of the members of the Committee on the Sale of Poisons, reappointed at the meeting in Hull, beg to report that they, in their individual capacity, and in conjunction with Mr. Jacob Bell, M.P., a member of the Committee on the Sale of Poisons, appointed by the Pharmaceutical Society, obtained an interview with Lord Carlisle on Saturday, the 22nd day of March.

As the Bill regulating the sale of arsenic, was to be

read a third time in the House of Lords on the succeeding Monday, there was no time for Dr. Toogood, Mr. Bell, and Dr. Sibson to consult their respective colleagues, they therefore thought no other course was left for them at that late period, than at once to communicate to Lord Carlisle the views of the two Committees, as embodied in their already published reports and petitions. In submitting those reports to Lord Carlisle, they impressed upon his Lordship the importance of supplying some omissions in his Bill. These were :—

That none but an adult male ought to be allowed to purchase arsenic.

That no person unknown to the vendor should be permitted to purchase arsenic, unless accompanied by a witness known to the vendor.

Lord Carlisle paid close attention to the representations made to him and to the reports of the Committees, which reports were left in his Lordship's hands.

The Bill which passed the House of Lords on the succeeding Monday, embodied the suggested provisions; but before the Bill was passed by the House of Commons, the provision limiting the power of purchase to males was struck out, owing to the indignant remonstrances of ladies.

With the valuable assistance of Mr. Hastings, barrister-at-law, the son of Sir Charles Hastings, and through the medium of Mr. Bell, Dr. Toogood, and Dr. Sibson attempted to have a clause introduced into the Bill enacting that if death from arsenic should ensue from the carelessness of any person having arsenic in their possession, such person should, on conviction, be liable to a penalty.

They were, however, unsuccessful in their efforts to obtain the insertion of such provision.

Dr. Theophilus Thompson mentioned that he was a short time since applied to for a quarter of an ounce of quinine, to poison a mountain grouse. He refused; but the applicant obtained it in another quarter.

President: The subject of poisons is a very important one, which will, doubtless, be again taken up with regard to other poisons.

Mr. Bree read a paper on "Sumbul," a new medicine used as an antispasmodic and stimulant.

The Address in Medicine.

Dr. King then read the "Address in Medicine," which was warmly applauded.

Dr. Malden was placed in the very enviable position of being requested to move "that the cordial thanks of the meeting be given to Dr. King, for his able and talented paper, and that he be requested to allow it to be printed." The comprehensive views, the warm heart, the cordial feeling, displayed in that Address,—the noble voice with which it was delivered, his splendid action, and his friendly manner, he was quite certain must not only be appreciated by their heads, but have warmed all their hearts. It was impossible to listen to eloquence like that—to wisdom like that—without having our hearts warmed by cordiality like that, without our feeling, under the influence of such "thoughts that breathe and words that burn," that they were becoming better and wiser men. There was one very large and expansive view taken of what was truth and what was falsehood in the eloquent speech of Dr. Cowan, of Reading. The same expansive view had been again taken by Dr. King. That was what enobled our minds. It was a view which had been beautifully summed up in Hooker's "Ecclesiastical Polity."

Dr. Hodgkin seconded the motion. He would be taking up the time of the meeting improperly if he were to attempt to add to what had been said; yet he would not be doing justice to himself if he merely, without observation, sat down. There were one or two points in the address which struck him. He was much interested in what Dr. King had remarked about the theory of waves, as applicable to parts of Brighton, in regard to the wind. Brighton, although exposed to winds, was not exposed boisterously, owing to the neutralization caused by the meeting of currents. He believed, however, that it was not merely quiet air that was to be looked to; the kind of air was an important consideration when sending patients away for change. Another point was the comprehensive view which Dr. King had taken of the requisites of a moral medical man. Observations had been made with regard to empiricism of various kinds. In the spirit of the resolution which had been passed he entirely concurred, but he felt a little hesitation as to their efficacy. To him it appeared that if medical men were to endeavour to carry out the views of Dr. King, and make themselves what Dr. King had shewn they ought to be, and let this be understood by the public, that would be the true safeguard of the profession. Various "isms" were springing up and deluding the public; but if physiology was better understood he believed that few would be willing to trust themselves and their families to homœopathists or hydropathists or anything involving a single idea. (Applause.) No man would trust his chronometers to a locksmith; and if human physiology were understood no one would trust himself or his family to those who pretended to do every thing by carrying out a single idea. (Applause.)

The President feared to say anything on the subject, after the truly eloquent address from Dr. Malden on the eloquent paper of Dr. King. To his colleagues in Brighton, there was nothing in it to surprise them, because they knew his excellent character, his goodness of heart (hear, hear); but he hailed it with delight, that such a paper should have been read to the meeting of this Association by a physician of Brighton.

The vote of thanks was carried by warm acclamation.

Anniversary Meeting, 1852.

Sir C. Hastings said it was understood that the next meeting of the Association would be held at Manchester, the metropolis, he might almost say, of that part of the kingdom. From the commencement of this Association to the present time Manchester had been one of their most important localities, and one from which the Association had received more support than from any other part of Her Majesty's dominions. It was therefore highly desirable that the Association should next meet there. With regard to 1853, he held in his hand a requisition from the Ipswich Committee

for the meeting to be held there. It was not necessary that the Association should now make any positive arrangement for 1853; still it was desirable that they should give some consideration to their future progress, because no doubt much of the success which had attended, and would attend the Association, depended on the places of meeting being judiciously chosen, and in their going to the right place at the right time. The success of this meeting at Brighton was owing to their coming at a most auspicious moment. With respect to the meeting at Ipswich, in 1853, Mr. Bree, the Local Secretary, informed him that the desire was, not so much that the meeting should be held at Ipswich, but that it should be held somewhere in the eastern counties. Under these circumstances, one of the Universities being situate in that district, and the Association having previously visited Oxford, he thought it would be desirable that the meeting of 1853 should be held at Cambridge. There had existed difficulties with regard to holding a meeting there, but he had reason to believe from communications received from gentlemen who were graduates of Cambridge, and were connected by close ties with the University, that the time was coming when the Association would be able to visit Cambridge with advantage. He now proposed that the meeting in 1852 be held in Manchester; and that W. J. Wilson, Esq., of Manchester, be President-Elect.

Mr. Hatton (Secretary at Manchester,) said it would, in 1853, be 16 years since a meeting of the Association was held in Manchester. Since that time the place had much increased; and this increase would enable the local branch to give the Association a more hearty welcome.

The motion was then agreed to.

This concluded the formal business of the Anniversary.

Communications, &c.

Several hours were then devoted to cases.

Mr. Caleb Williams (York) read a paper on the change, during the last thirty years, in the types of disease.

Dr. R. Hall read a paper entitled "Observations with Hutchinson's Spirometer."

Dr. Sibson exhibited an improved form of his "Chest Measurer."

Mr. Smith (Southam) read a curious paper, tending to show that the diminution of the age of man since the creation, had been not *gradually*, but by jumps; and that in each case, some great sin, such as pride, lust, idolatry, hardness of heart, had been precedents of those changes He enforced the importance of our adopting the opposites of these, which might have the effect of diminishing disease, and prolonging life.

Mr. Lord of Hampstead, now rose on behalf of Mr. Propert, who was, unfortunately, hastily summoned to London, and enforced on the Association the importance of supporting the benevolent idea of Mr. Propert, for forming a Benevolent Medical College, for the support of the widows, and the education of the orphans of deceased members of the profession; and a resolution in support of the plan was then moved, and carried unanimously.

Mr. Bottomley read a paper, detailing the successful treatment of a curious case of gangrene in the foot and leg.

Mr. Domville read a paper on the causes of deafness.

Dr. Crisp read a paper, the object of which was to show that kousso was not a specific for tape-worm.

Dr. Hunt read a paper on the skin, as a diagnostic of health.

Dr. Oldham read a paper descriptive of a successful Cæsarean section under chloroform. He recommended an opening from below, as small as possible, to be afterwards enlarged according to necessity, instead of resorting at first to the major operation, so as to avoid excessive hæmorrhage.

Dr. Tunstall moved the thanks of the Association to those gentlemen who had read cases and made communications to the meeting.

Mr. Crang seconded the motion, which was carried unanimously.

Dr. Conolly said there was one duty which the meeting would have great pleasure in discharging. It would be manifestly wrong to separate without giving some form of expression to the feelings which the excessively kind reception given to the distant members by Dr. Jenks, and those associated with him, had called forth. To himself it was an especial pleasure to again meet a gentleman whom he had had the honour of knowing for some years, and of knowing from report before how much he was respected by his townsmen. As his kindness, urbanity, excessive patience, and the many other good qualities which he had displayed in the chair, it was unnecessary to dilate. He would, therefore, at once gratify himself, and he was sure he should gratify all present, by proposing their best thanks to Dr. Jenks, for his reception of strangers, and for his conduct in the chair.

The motion having been seconded by Dr. Hodgson, was carried by acclamation,

The President returned thanks, merely remarking that their kind expression of feeling towards him would be always a gratifying recollection.

An adjournment now took place, at five o'clock, to afford an opportunity for the members to prepare for

THE DINNER,

Which took place in the Royal Banqueting Room, recently converted by the Brighton Town Commissioners into a splendid mansion, slightly differing from, but scarcely less gorgeous than when used for the reception of Royal guests in the time of George IV., under whose immediate direction it was designed, built, and decorated.

Dr. Jenks was again in the Chair. There were about 250 present, including in addition to the members of the medical profession, the Bishop of Chichester, the Rev. H. M. Wagner, Vicar of Brighton, the Rev. T. Ccoke, the Rev. S. R. Drummond, Rev. J. Nelson Goulty, Montague Scott, Esq., High Constable of Brighton and Magistrate, W. Furner, Esq.,

Magistrate and Judge of the County Courts of Sussex, Eardly N. Hall, Esq., Banker, Lewis Slight, Esq., Clerk to the Brighton Commissioners, P. R. Wilkinson, Esq., &c. &c.

The band of the 1st Dragoons (Royals) played before and during dinner; and some professional singers, local and metropolitan, had been engaged for the occasion.

The dinner, provided by Mr. Shaw, of the Steyne, was aldermanic.

The PRESIDENT gave "the Queen," that illustrious lady whose dominions extend over the seventh part of the earth's inhabitants, and more than a seventh of its surface, but whose kingdom at home was the little island in which we lived,—this little pearl set in the silver sea. The toast was drunk with three times three, the "honours" being subsequently tacit and imagined.

"God save the Queen" was sung by Mr. Hobbs, from London, the whole company joining in the chorus.

The PRESIDENT then gave "Prince Albert and the Royal Family." The Prince Albert had been an ardent promoter of scientific institutions, and patron of the fine arts, and he had this year immortalized himself by proposing and carrying out the Exhibition of the Industry of all Nations. In nothing has he shown his discrimination more than in adopting Mr. Paxton's design for the Crystal Palace, a wonder which surpassed all the wonders of this our day. (Cheers.)

The PRESIDENT then said the next toast he had to propose was one which he was sure would receive the full assent of those present. There was no body of men who could better appreciate the services of the clergy than members of the medical profession. The two professions, though not equal in dignity and importance, were often associated in the same work, actuated by the same noble feeling, that of benefitting mankind. What physic was to the body so much and more was the sovereign balm of religion to the stricken conscience and the troubled spirit. (Hear.) On this memorable occasion the respected and venerated Bishop of Chichester—(cheers)—had done them the honour to partake of their hospitality. He was well known in his diocese for his uniform piety, his loving and peaceful bearing, and his paternal and Christian-like government of those committed to his spiritual care. He had singular pleasure in seeing so many of our Brighton clergy present at this feast. (Hear.) Whatever view they were regarded in,—whether we looked to their duties as faithful teachers, or their assiduous labours among the sick, or their invaluable services as promoting the charitable institutions of the town, it was but common justice they should render them thanks in the toast he proposed,—"The health of the Bishop and Clergy of the Diocese."

The BISHOP OF CHICHESTER, in reply, expressed the satisfaction he felt at being enabled, contrary to his expectation, to accept the invitation which he had received, through Mr. Cordy Burrows, to attend the present festivity. He felt most fully the bond that should ever unite the Clergy to the honourable and useful profession which was adorned by so many persons of eminence now in this room; for if, on the one hand, the medical men were pleased to say that in their visits to the sick chamber they found traces of the advantages reaped by society from the labours of the clergy, on the other hand, no clergyman could, in a place like Brighton, so abounding in hospitals and other institutions for the benefit of our poorer brethren, fail to have forced on his attention, by facts speaking for themselves, constant traces and noble instances of the desire of the profession to make their skill and science available for those for whom the clergy were bound to be assiduously interested,—our poorer brethren. And when God's providence visited us or our families with sickness we uniformly found that not only did members of that honourable profession bring the advantages of their skill and experience to relieve our maladies, but they were always ready and anxious to add a soothing and kind exhortation to the temporal blessings which they conferred. We did, then, all gratefully acknowledge that, whether we looked to the labours of the medical profession among the poor, given gratuitously and most liberally, or whether we looked to them as we saw them in our own families, giving their skill and science in a manner which enhanced their value, their services were most valuable. Although, perhaps, not fully, he could in some degree, enter into the enjoyment which the profession must have had in meeting from all parts of the island, in this town, gentlemen perhaps engaged in their earlier days under the same lecturer, walking the same hospital;—(hear, hear)—and who, perhaps, owing to circumstances, had since been separated north and south, east and west, being once again brought together. And the respected founder of this institution would perhaps allow him to say that not the least of the benefits he had conferred on the profession was connecting it with anniversary meetings, when friends might meet after long intervals to compare their success through life, improve each other by confiding the discoveries and the advances in knowledge made in their common profession, and, lastly, by joining hands together in that friendship which began in early years. These constituted one of the greatest charms of the meeting. (Cheers.)

The PRESIDENT said the next toast he had to propose was,—"The Army and Navy." It was quite unnecessary to say anything in recommendation of this toast. The achievements of our soldiers and sailors had become "familiar in our mouths as household words." But there was one body connected with both services of which, in a company chiefly composed of medical men, he might be allowed to speak—the medical officers of the army and navy. (Cheers.) They knew that of old, Homer thought one medical officer was worth a good many fighting men, as Butler had translated it,—

> "A skilful leech is better far
> Than half-a-hundred men of war."

It was impossible to pass too high an encomium on those devoted men. The whole world, all climates from the equator to the poles, had been the scene of their labours. He was informed that the records of the Directors-General of the Army and Navy contain numerous reports on the diseases and medical peculiarities of all the known races of men, upon the medical topography and natural history of every climate. Some day he hoped a digest of these valuable documents would be made, for the use of the profession, and the benefit of mankind generally.

"Rule Britannia" by the company.

The PRESIDENT would next propose "The Provincial Medical and Surgical Association." (Prolonged cheers.) He was sure that would be received with acclamation. He wished only that he could do full justice to it in the few words he should have the honour of saying. After the nineteen years' experience it had enjoyed, it would be superfluous for him to enter upon the important benefits connected with this noble Association, especially as everything that could be said in praise of it had been said already over and over again, and said with eloquence and ability far beyond his reach. But it was sometimes desirable, and always pleasing, when trials and difficulties were passed, to reflect on what we had gone through, and compute our gains. Many there present would recollect what twenty or twenty-five years ago the state of the profession in the provinces was. There was no bond of union between professional men, they were, indeed, seldom known to each other. There was much contention about rights and privileges which a little friendly intercourse would have cleared up, but for want of which medical practitioners indulged in enmi-

ties, dissent, and jealousies, which made them the theme of ridicule of all the shallow wits and solemn babblers of the day. This was "the winter of our discontent," but all this, while there was a deal of good among them, much benevolence, great aptitude for good-fellowship and kindly feeling, much learning and industry, great store of valuable truths, rich treasuries of knowledge;—all this was scattered widely upon a stormy sea, and all in great danger of being lost for want of a helping hand. At this juncture there arose, like old Neptune, a master spirit, the clouds and darkness were quickly dispelled, and the cheerful light of day restored. He who brought about all this, the man whom they should delight to honour, was Sir Charles Hastings. (Cheers.) He founded the medical profession in the provinces, the chaos of disturbed and conflicting elements united about him, were fused together, and resulted in an institution, which from the commencement to the present day had enjoyed one uninterrupted career of prosperity. What was disunion, through him became united; what was a weak and defenceless body had now attained power and influence. (Hear.) Power and influence had "grown with its growth, and strengthened with its strength." They owed a deep debt of gratitude to their worthy founder—a debt they were in no hurry to wipe off, had no anxiety to forget, but one they were content, nay, willing and happy to pay yearly interest for, in the shape of grateful thanks, affectionate remembrance, and all the honour they could bestow,—(hear)—long might he live so honoured and so loved. (Hear.) He should propose, "Prosperity to the Association, and health and prosperity to its founder, Sir Charles Hastings." (Cheers.)

Sir Charles Hastings could not remain silent, although he feared that any endeavour on his part adequatety to thank them would fall far short of his desire, but he begged the Association to accept his imperfect attempt to embody in language his feelings of respect and gratitude to all. It was now touching upon twenty years since he was first associated with many friends whom he saw around him in commencing this institution, and since in carrying forward its objects and purposes, and it was a feeling constantly present to his mind—a feeling of pride and joy, that he should be considered the founder of an Association which promised to be of much importance not only to medical science but to mankind at large. (Great applause.) At their Anniversary Meetings he had had the pleasure of renewing many old friendships, and of making many new ones, so that he could but regard this Association with the deepest feelings of affection, and he supported it with his weak powers to the utmost. The objects which the Association contemplated and wished to carry out were of the utmost importance to their science. When years ago they unfurled their banner, what did they inscribe on it? what was their motto? Maintenance of the honour of the profession; union and good-will among all the members of legitimate medicine—(cheers);—succour to the widow and afflicted—(hear, hear);—improvement of medical polity; advancement of medical science. This was their banner, and under that banner they had manfully fought,—they had fought a good fight. In the battle-field the cry was—

"Charge, Chester, charge; on, Stanley, on;"

in their field, the field of science, "ride on" should be their watchword. This hitherto had been the principle which had guided them; this it was which had enabled them to accomplish the object which they originally contemplated, this it was which had enabled them to place on their records a memorial of their existence, a memorial which would long remain after they were silent in their graves. He trusted that a feeling of gratitude towards them for having supported his humble efforts would be ever present to his mind. He felt that these anniversary meetings were the bright spots in his life, and he trusted that whatever might be the imperfections which they yearly and daily must perceive in his acts, they would ever consider him their devoted servant, their faithful friend, their attached brother. Let them endeavour to inscribe on this Association the motto *esto perpetua*, and then they might say to those who came after them, "There was a time when the profession in the provinces was disjoined, was dissevered, but by the founding of this Association anew era in the history of medicine arose, a body of men were collected together for the best purposes, peace and harmony being their polar star. They associated together, and handed down to those who succeeded them an Association which had for its object the advancement of mankind—the advancement of medical skill, but still more the common benefit of the whole human race." (Cheers.) At that late hour (nearly midnight) he would trouble them no further. These few remarks would, he trusted, give expression to the feelings which animated him, and he hoped that in future years they would continue to go on conquering and to conquer, and that each advancing year a periodical benefit as great as that which they had seen at the present would occur. To pass from himself and his own doings, and call the attention of the meeting to their duty at this anniversary, in this marine palace, surrounded by circumstances calculated to please the fancy, and to act in every way on the best feelings of our nature, he begged to call attention to their worthy President—(hear, hear)—who had at this present anniversary won for himself golden opinions from all parties. Whatever might be the names of those who preceded him in his high office, he would hand over to his successor this chair not at all damaged, but on the contrary, dignified by the manner in which he had at this anniversary carried out the objects and purposes of this noble Association. (Cheers.) The health of "Dr. Jenks, and thanks to him for the important benefits which he had conferred on this Association by presiding over it." (Loud applause.)

The President, in rising to return thanks for the honour done him, found he had arrived at the most difficult part of the duties of his office. He was most grateful to the meeting for the kind manner in which they had responded to the toast, and to the members for the honour they had conferred on him in electing him to the post he filled. He should ever regard it as the culminating point in his medical life. To his friend Dr.—he begged pardon, Sir Charles—Hastings, he was deeply indebted for his kindness in proposing this toast, and for the flattering encomiums he had been pleased to pronounce on him. *Laudari a laudalo* was a truth to which he was feelingly alive. He was only sorry that he could not realize to himself that he had done sufficient to deserve the thanks so freely bestowed.

After a brief interval:

The President rose and said,—the medical faculty were represented at that board by the President of the Royal College of Physicians, Dr. Paris. All who had had any transactions with that gentleman were aware of his unvarying kindness and urbanity, and the dignity with which he presided over the learned body he represented. He had much pleasure in proposing "Dr. Paris and the Royal College of Physicians."

Dr. Paris, in reply, thanked the President for the handsome manner in which he had proposed, and the meeting for the cordiality with which they had received and responded to the last toast. He was fully aware of the honour done him. He came for the purpose of expressing in the name of the College of Physicians the satisfaction felt by that body at the assembling together of so much talent as is united in this Association, as such gatherings, it was felt, could not fail to conduce to the best interests of the profession. He looked forward with the warmest anticipations to the progress of that intelligent body of men; it was for them and them

only to determine what should be the future state of the medical profession. (Hear.) They were aware that when the College of Physicians was informed that it was the desire—the general desire of the profession, that there should be a third body or College, their answer was simply this,—"If it is the desire of the profession at large to have a third College, we see no objection. We have our private opinions; we don't think it would advance the interests of science or the dignity of the profession, but we have nothing to say against it." For more than six nights they sat from nine till twelve, recieving delegates from all quarters, and the only question with them was,—Did the general profession desire it—did they think it would conduce to their advantage, and to that of the public also? If so, the College of Physicians was perfectly ready—he stated this officially—the College was perfectly ready to follow and carry out any design which the general body of the profession desired. (Prolonged cheers.) He would only, in addition, thank them and drink their very good healths. (Cheers.)

The PRESIDENT said it would ever be memorable in the annals of this Association that, besides the President of the College of Physicians, there was present on this occasion the President of the College of Surgeons also. (Cheers.) He trusted this might prove a happy omen; he hoped that this evening would prove that they had the right spirit among them, while it tended to promote good fellowship. Mr. South was well known to a great part of them, both in his literary character, and as an excellent surgeon. He begged to propose Mr. South and the College of Surgeons.

Mr. SOUTH begged to express his great gratification at the opportunity of meeting the Association that day, and he felt the gratification especially, because he was the first President of the College of Surgeons who had ever met the Association. (Cheers.) He felt still greater pleasure, because he could come among them, and not, as his worthy friend the President of the College of Physicians said, promise what he would do, but tell them what they had done, and remind them that the Government had received favourably the proposals for improving their College and obtaining a new charter. (Cheers.) He was not a very old man, if he was a very young President, but there were among the members of the Association a great number of persons with whom he had been long acquainted, many fellow students and pupils of his own, and it gave him extreme satisfaction to meet them at Brighton, and he felt assured that he was only expressing most honestly and sincerely the feeling of gratification of the Council of his College at receiving the invitation of the Provincial Association to be present on this occasion. It was truly said by the President of the College of Physicians, that upon the profession itself depended what the profession should be. The College of Surgeons could make laws, but had no power to enforce their observance. If the profession liked them, they could come among them; and if they did so come, it must be because they considered it an honour to themselves to be enrolled in the College. (Hear.)

The BISHOP proposed "Prosperity to the town of Brighton,"—a place which contained one-sixth of the population of his diocese—a place which, from the absence of decaying vegetable matter and the salubrity of its air, was a most valuable adjunct to the efforts of the medical profession in the restoration of health. Connected with this toast the Bishop proposed the High Constable of the Hundred, "Montague Scott, Esq.,"—a Magistrate of the county, and son of the late Sir David Scott, whose family had always stood high in the estimation of all sections of the inhabitants of the town.

The toast was received most enthusiastically.

Mr. SCOTT, on behalf of the inhabitants of Brighton, had the honour of returning thanks for the compliment so kindly acknowledged. The town of Brighton owed much to the medical profession, for it was a gentleman of that profession, Dr. Russell, a man of acknowledged ability, who, having devoted his attention to the cure of diseases by sea-water, first drew the attention of the fashionable world to Brighton, and raised it from a mere fishing village to an extehsive town.

The Rev. Mr. WAGNER, (Vicar of Brighton), after a few complimentary remarks directed to the medical profession of Brighton, who, he said, were second to none in the kingdom, proposed the "County Magistrates, and Mr. Furner, Judge of the Sussex County Courts"

Mr. FURNER briefly returned thanks.

Dr. CONOLLY proposed "Mr. Newnham, the Treasurer of the Benevolent Fund."

Mr. NEWNHAM's reply was scarce audible, but it was devoted to a kindly acknowledgment of the services of those gentlemen who aided his labours, and so rendered the Fund available throughout the country.

Dr. CONOLLY gave the health of those gentlemen who, not belonging to the Association, were present as visitors. In relation to the foreign visitors in England at present, he said, Dr. King had in his address told us, there were certain currents of air, which, meeting, produced a calm. They were now in a time when currents were coming from all quarters of the globe, and he trusted to God they might produce a calm that might last for ever. (Applause.)

M. BATELLE, from Paris, returned thanks in French.

Dr. MALDEN proposed the health of Mr. Cordy Burrows, to whose zeal and unremitting labours they owed their admirable reception in Brighton. On the conduct of Mr. Burrows in his "labour of love" in conducting the meeting, and also as acting in the capacity of Hon. Secretary, he passed some very high encomiums.

Mr. BURROWS assured the meeting that the Local Committee had, individually and collectively, had but one motive, and that was that this, the nineteenth meeting of the Association—an Association approaching to manhood—should show the vigour of manhood; that year by year as the Association increased in age it should increase in importance. If the Committee had, by their exertions, assisted in promoting the interests of the Association, he was quite sure they would be amply recompensed. When the Association determined on visiting Brighton he was requested to act as Secretary. He assented, for he believed that the interest of every one was bound up in the prosperity of the medical profession. He had had great pleasure in attending the meeting, and, at this late hour, he would only say that he hoped to live long enough to see the Association again in Brighton.

The meeting, a most delightful one from beginning to end, came to a close soon after midnight.

Medical Intelligence.

THE COLLEGE OF SURGEONS AND THE MANCHESTER MEMORIAL.

To the Right Honourable Sir George Grey, Baronet, Her Majesty's Secretary of State for the Home Department, the humble memorial of the undersigned Members of the Royal College of Surgeons of England practising in Manchester and its vicinity showeth, That while your memorialists express their pleasure at the concessions recently made by the Council of the College to its members, they cannot allow the opportunity to pass without testifying their dissatisfaction at the position in which your memorialists will be placed by the carrying out of the Charter of 1843, as at present proposed. That the denying to your memorialists the

privilege of being admitted to the Fellowship after the proposed term of membership, without examination, while it is granted to all gentlemen who have been 15 years members of the College, and whose diplomas dated as such previous to the granting of the Charter of 1843, will operate upon your memorialists with manifest injustice, since your memorialists, for several years previously to that time, entered upon a much more extensive curriculum of surgical education, in the hope of holding a guaranteed position in the College, and of which position your memorialists will be unjustly deprived by being placed in a lower grade in the profession. That this retrospective operation of the Charter is contrary to the usual practice of the College, since students registered as such, and preparing for examination, have never been made amenable to laws passed after the commencement of their studentship; and your memorialists beg to assure you, Sir, that they have no objection to the examination as a test of merit for the fellowship, simply considered as such; yet, if this distinction is to be granted to any gentleman without examination, after a certain term of membership, your memorialists believe that their claim to that privilege, upon every ground of equity and fairness, is unanswerable. Your memorialists, therefore, respectfully beg you, Sir, in any measure you may be pleased to propose on behalf of Her Majesty's Government, to allow all gentlemen who commenced their surgical studies before the grant of the Charter of 1843, and who have subsequently been admitted Members of the College, to be admitted to the Fellowship upon the same terms as those gentlemen who were Members of the College at the period of the promulgation of the Charter. Your memorialists also beg to state, that they will have no objection to pay such fee as the Council of the College may think necessary; and your memorialists further desire to assure you of their continued attachment to the College, and of their wish for its prosperity and dignity, and to manifest their repugnance to the establishment of any rival body; yet at the same time, with every feeling of respect, to express, that your memorialists can never rest satisfied that justice has been awarded to your memorialists, unless their prayer be approved and granted. And your memorialists will ever pray. Peter Royle, 21, Lever Street, Manchester; John Walsh, 36, Oldham Road; Joseph M'Neand, 107, Grosvenor Street; George Morley Harrison, 59, Dale Street; George M. Burton, 83, Grosvenor Street, Chorlton-on-Medlock; R. Bellhouse Midwood, Grosvenor Square; James Rhodes, 61, Dale Street; James Ogden Fletcher, 24, Dale Street; George Vause Birks, Grosvenor Square; Joseph Edmund Roystran Nadin, 14, Vine Grove, Hulme; John Wells Wainwright, Burlington Street; Robert Manners Mann, 9, Tonman Street, Haymarket; Edmund Lund, 22, St. John's Street; John Shepherd Fletcher, 27, Lever Street; William Hall, 7, St. Stephens Steeet, Salford; Thomas Kay Holland, 101, Greengate, Salford; Alexander Somers, 27, St. Stephen's Street, Salford; Henry Winterbottom, 66, Great Ducie Street, Strangeways; Roydon Jackson, 270, Great Union Street, Manchester; Samuel B. Bennett, 182, Oxford Street, Chorlton-on-Medlock; Henry Merrill Williamson, Dispensary, Chorlton-on-Mdlock; James Jodrell Cooke, Hope Street, Piccadilly. (The signatures to the memorials have been restricted to those gentlemen alone who commenced their studies previous to, and who have passed the College on or since November, 1843.)

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on Wednesday, the 30th ult.:—James Andrews, Pershore, Worcestershire; John Dale, Yarm, Yorkshire; James Sherwood, Notttng Hill; Francis Martin, Brighton; John Salusbury, Denbigh, North Wales: Walter Smith, Caistor, Lincolnshire; Charles Joshua Tovell, Hadleigh, Suffolk; John Freeman Wright, Edward's Street, Portman Square.

The following gentlemen were admitted on Thursday, the 31st ult.:—Robert Howarth Blake, Birmingham; Charles Edward Buckoli, Brighton, Sussex; William B. Chavasse, Birmingham; James Richard Alexander Douglas, Arundel, Sussex; Edward D'Arcy Evezaid, York Buildings, Regent's Park; Key Hardey, Great Carter Lane, Doctors' Commons; David Jones, Liverpool; Watkin Rhys, Aberdare, Glamorganshire; Julius Wiles, Hitchin Herts.

The following gentlemen were admitted members on Tuesday, the 5th instant:—James Alsop, Bolsover, Derbyshire; Robert Hannay Cunningham, Lima, South America; Thomas William Fox, Leicester; Francis Goodwin, Newtown Butler, county Fermanagh; John Robert Hughes, Rhyl, Flintshire; William Thomas Irvin, Omagh, county Tyrone; John Ker, Tipton, Staffordshire; John Jones, Dyffryn, Merionethshire; James Nowell, Bradford, Yorkshire; Samuel Bowen Partridge, Newport, Monmouthshire; James Speak, Newcastle, Staffordshire; Henry Benjamin Wood, New Romney, Kent.

The following gentlemen were admitted on Friday, the 8th inst.:—Walter Alexis Bridge, Nicaragua, Central America; John Ansell Brown, Surrey Square, Old Kent Road; Cornelius William Dennehy, Cork; James Dickson, Charlestown, South America; Henry George, Kirton Lindsey, Lincolnshire; Henry Spry Leverton, Truro, Cornwall; Maurice James O'Connor, Morpeth, Northumberland; John Bredin Posnett, Belfast; Charles Rothwell, Bolton-le-Moors, Lancashire.

The following gentlemen were admitted on Monday, the 11th instant:—Francis Ayrton, Liverpool; Frederick William Hart Bayes, Stiffkey, Norfolk; William Henry Borham, Edgware Road; George Crosland, Wakefield, Yorkshire; George Dixon Drury, Emsworth, Hants; Richard Ridge Dyer, Taunton, Somerset; William John Alexander Orr, Dublin; Andrew Spearing, Cork; Arthur Stretton, Wandsworth, Surrey.

SOCIETY OF APOTHECARIES.

The following gentlemen were admitted on Thursday the 31st ult.:—Alexander Fraser Bayne, Reading; Frank James Wilson Packman, Puckeridge, Herts; Henry Seatle, Ulverstone, Lancashire; Julius Wiles, Hitchin, Herts.

The following gentlemen were admitted on Thursday the 7th ult.:—Sidney Haynes, Sandwich, Kent; William Henry Pearce, Launceston, Cornwall; Alonzo Henry Stocker, Sloane Street, Chelsea; Charles Henry Tovey, William Williams, Birmingham.

A COURSE OF LECTURES ON SURGERY,

DELIVERED IN THE

MEDICAL SCHOOL OF CAMBRIDGE

By GEORGE MURRAY HUMPHRY, Esq.,

Downing College, Surgeon to Addenbrooke's Hospital.

Lecture XXXI.—Epithelial Cancer.

The points of difference and resemblance between it and the other varieties of cancer; cancer of the lip; its progress and treatment: cancer of the penis and scrotum; the relation of cutaneous cancer to simple cutaneous wart, and the probability that the latter sometimes degenerates into the former, considered and illustrated by cases. The degree in which the structure of cutaneous cancer differs from the natural structure of the skin, is usually proportionate to the malignancy of the disease. Epithelial cancer of the mucous membrane of the mouth and tongue; its malignancy greater in this situation than when it affects the skin. Epithelial cancer of the bladder, urethra, and stomach.

The several varieties of cancer may be conveniently grouped into four species, viz.:—1, epithelial cancer; 2, scirrhous and encephaloid cancer; 3, melanic cancer; 4, alveolar or gelatiniform cancer. All these present some differences in their general appearance, their microscopical characters and their progress, sufficient to require a separate description; at the same time it must be observed that their distinctive peculiarities are not always well marked; two or more of them are occasionally found in the same person; and they all agree in presenting that power of assimilating and destroying the neighbouring tissues, and that tendency to spontaneous decay which I have described to be characteristic of cancer.

The epithelial cancer affects usually the skin or a mucous surface in the first instance. It differs from the other forms of cancer in being composed almost entirely of cells more or less flattened out and closely resembling those of ordinary epithelium; it does not present the malignant qualities in so marked a degree; it is more tardy in its progress, sometimes remaining for months or years in a quiescent state, or growing very slowly; it generally appears at some part of the skin or mucous membrane which has been exposed to a long-continued irritation, and its ravages are confined to the vicinity of that spot and to the adjacent absorbent glands; that is to say, it does not often make its appearance in any other organ, being, in a greater measure than the other forms of cancer, a local affection, less associated with any particular diathesis and much less likely to return after extirpation.

For these reasons some pathologists are inclined to exclude the epithelial species from the family of cancer; mistaking, as it appears to me, differences in degree for differences in kind, inasmuch as the epithelial disease does really present all the leading features of cancer, though it may do so in a less decided and less active manner than the other members of the class. It is attended with the destruction of the original tissues wherever it occurs; it possesses the quality of spreading from point to point, assimilating the adjacent tissues of every kind and in every direction, and reducing them all to one homogeneous structure; it affects the neighbouring absorbent glands, converting them also into a substance like the parent mass; and it is prone to decay and ulceration: moreover, it is unceasingly destructive; it yields to no treatment and pursues its relentless course till death puts a stop to its ravages.

Watch the progress of the disease when it affects the lip, by far its most frequent seat. It usually begins on the edge of the lower lip a little to one side of the middle line, probably at the spot where the pipe is habitually rested. I have seen it in the middle of the lip, originating in one of those cracks which are often so troublesome in that situation, and in two or three cases have met with it in the upper lip; in one of the latter it originated in the cicatrix of a wound inflicted several years previously. A slight thickening or wart-like elevation of the skin is generally the first symptom; the cuticle is also thickened at the part, and in course of time becomes rubbed or scratched off, leaving the surface a little abraded or cracked, or superficially ulcerated. Upon this a succession of scabs are formed and detached, while an increasing lump is produced underneath them and the ulceration proceeds deeper; so that in the course of time a considerable ulcer is engendered with an indurated basis, an excavated, or deeply fissured, or warty surface, covered with white dirty secretion, or perhaps with pale firm granulations, and having a sinuous, raised, everted margin. The discharge from these ulcers is thin and pale, like serum; occasionally it is mixed with blood. They are not painful or tender, and the patients often think little of them. However, they gradually increase extending along the margin of the lip and towards the chin, the thickening and induration preceding, the ulceration following, till the whole lip and part of the cheek may be involved in the disease. Before such extensive ravages have been effected the absorbent glands under the jaw are generally found to be enlarged and hard, the skin over them becomes adherent and inflamed, and ultimately giving way, an ulcer is formed which extends deeply, presents the usual cancerous aspect, and leads to the like fatal termination. If a section be made through the ulcer in the lip, even in an early stage, its indurated basis is found to consist of a compact, opaque white, pearly substance, of uniform appearance, or speckled, it may be, with small yellowish spots, which are softer than the rest of the mass and which are generally situated in greatest numbers near the ulcerated surface. In this substance all the natural tissues of the lip are blended and lost. Not only are the skin, the mucous membrane, and the labial glands transformed, or assimilated by the new structure, but the muscular fibres of the orbicularis as well as the areolar and fibrous tissues are traceable into the mass and are lost

in it. When examined under the microscope the new substance is found to be composed almost entirely of flattened cells, like those of epithelium, compressed together and arranged in laminæ superimposed upon one another. Some of those which are newly formed or which are swollen by the imbibition of moisture are round, oval, or fusiform, and present nearly the characters of the ordinary cancer cell. It is an interesting fact, first announced, I believe, by Mr. Paget, that the microscopical characters of the diseased absorbent glands correspond with those of the primary disease in the skin; the glands, like the tissues of the lip, being converted into masses of flattened and closely compressed scales, intermixed with cells in various stages of transformation. This fact, taken in conjunction with the acknowledged success that attends the removal of epithelial cancer of the skin, makes us somewhat bold to extend our incisions for the purpose of extirpating also the morbidly affected glands.

The disease is most commonly seen in elderly men, though middle-aged and even younger men are sometimes affected by it. The patient's health generally appears to be good till it becomes impaired by the distress, discharge, and inability to masticate, occasioned by the extensive destruction of parts about the mouth. A complete and permanent cure in most instances follows the entire removal of the mass by the knife, which should be done at an early period; before the absorbent glands are involved, if possible, because they are sure to enlarge and lead to the results just described when they have begun to participate in the disease. Occasionally we find this to be the case after the operation, although there was at the time no evidence of their being in a morbid condition. In three or four cases, after the removal of the mass from the lip, and when the cicatrix remained perfectly sound, I have known the disease spring up in the periosteum, make its way through the jaw, and destroy the patient. Even the complete excision of the portion of the jaw thus involved does not always save the patient.

In the cancer of the penis and of the scrotum the progress of the disease is very much the same as in the lip; the ulcer originating in a pimple, a wart, or a little thickening of the skin, has the same foul or coarsely granulating surface, everted edge, and indurated base, goes on increasing with equal or even greater virulence, involves the inguinal glands, and destroys the patient in a shorter space of time than the corresponding affection of the lip. I have seen the disease at the anus, on the extremities, the trunk, the face, and head, and believe it may attack the integuments at any part of the body. It presents very much the same characters and runs the same course in whatever situation it occurs; exhibiting the qualities of malignancy in a sufficiently marked manner; quite as strongly, indeed, as we could expect, considering that it is very generally the result of some local irritation.

Nevertheless it must be admittted, and this is one of the most interesting features in their pathology, that these cutaneous growths vary a good deal in their malignancy; so much as to constitute, it would seem, a very instructive link between simple hypertrophy and genuine cancer—between an ordinary wart and well-marked scirrhus, proving that these diseases must be studied in their relation to one another no less than in their points of difference, if we would attain a correct idea of their real nature. There is good reason to think that the neglect of this mode of considering the subject, together with the too great stress which is usually laid upon the distinctive features of cancer, has been the source of many narrow views, if not of much misconception, upon this very important class of diseases. Any information upon the subject which the cutaneous growths may afford is peculiarly valuable, because they are directly under our observation; and if there be any relation between simple and malignant disease we may expect to find some evidence of it in them.

Now, there are numerous instances of warts occurring upon the skin in elderly persons, respecting which we have a difficulty in deciding whether they be cancerous or not, and which we are in the habit of extirpating, because we know that if they be allowed to remain they will go on increasing, will in the long run ulcerate, affect the adjacent glands, and terminate fatally. For example, a healthy man, aged 63, was in John's ward a year ago with a broad, flat, warty growth on the right temple; it overhung the surrounding integuments, which were purplish and a little pimply. The surface of the growth was covered by a soft white secretion, and when this was washed away it was seen to be granular and warty, with superficial ulceration at places. There was no induration about its base, and no enlargement of the adjacent absorbent glands. It had commenced a year and a half previously. About the nose were several small pimply or warty elevations of the cutis, which he said had existed for a longer time than that on the temple, though the latter at its commencement resembled one of them. I removed the growth, completely dissecting it away from the temporal fascia, to which it was loosely connected by cellular tissue. After the wound had healed there was a return of the disease at one spot in the edge of the cicatrix, requiring a second operation, which left him quite well. A short time ago the part was sound, and the warts on the nose remained unaltered. A section of the mass showed it to be composed of pale, blunt, thick fibres, parallel to one another, and at right angles to the surface of the body, doubtless enlarged and elongated papillæ, together with epithelial sheaths of papillæ. This appearance is often seen in cases of the like kind, and is probably the result of a change analogous to that which causes the thickened striated condition of the intestinal muscular coat accompanying cancer of the bowel. The association of an actively increasing warty growth with a number of others of similar appearance which remain in a quiescent state is very common. I remember a chimney-sweep, the subject of cancerous ulcer of the scrotum, whose skin was covered in many parts of the body with little warty elevations, attributed by him to the same cause as the more malignant disease

in the scrotum, viz., the irritation of the soot. They were in a quiescent state, and hardly attracted attention.

In the following case a disease precisely similar in appearance to that just described, but more slow in its progress, was neglected, and proceeded to a fatal termination. A healthy-looking man, aged 65, presented himself at the hospital, several years ago, with an extensive warty growth, affecting the whole of the lower lip, the angles of the mouth, and a portion of the upper lip. It extended to the chin, and was adherent to the mental portion of the jaw, the mucous membrane of the gum being involved in it. It had a cauliflower-like appearance, was of considerable thickness, and overhung the surrounding skin, terminating on all sides in a well-defined edge. On one side its level had been reduced a good deal by ulceration, and there was some enlargement and induration of the absorbent glands under the chin. The affection commenced with a small pimple on the margin of the lip ten years previously; this increased slowly at first, but latterly with greater rapidity. He had made up his mind not to submit to any operation, returned home, and died.

A hale man, a shepherd, aged 72, was in the hospital, in November, 1849, with a prominent warty or cauliflower-like growth at the upper and inner part of the left thigh. It was deeply fissured and ulcerated, but quite moveable upon the fascia beneath, and could, therefore, easily have been extirpated; but the femoral and inguinal glands were enlarged and indurated, some of them in close contact with the femoral artery. It was judged useless to remove the growth and leave the diseased glands; and the man not being willing to submit to such an operation, went home. I heard subsequently that the cutaneous growth had been removed, but that the disease was proceeding to a fatal issue in the groin. The patient said that this growth had commenced at least twenty years previously, in the form of a small wart, which had increased gradually; latterly its progress had been more rapid. At the time we saw it there was little doubt of the malignant nature of the disease in the affected glands, as well as in the cutaneous growth, and of its incurability by any proceeding short of complete extirpation. Yet it had existed for many years as an indolent harmless growth, causing no discomfort to the patient, and exciting no apprehension of its ultimate termination. In such a case it would seem most probable, not that, according to common parlance, cancer had been engrafted upon a simple wart, as if they were altogether distinct diseases, but that the tissue of the wart had gradually degenerated in such a manner as, in course of time, to become liable to spontaneous decay and ulceration; and that the degeneration, and the destructive processes connected therewith, had a tendency to spread among the surrounding structures, and was associated with a general increase of activity in the disease, in consequence of which the absorbent glands participating in the morbid process exhibited a similar malignant disposition. If this view of the matter be correct it would follow that in the preceding, and in other cases of the like kind, there was a gradual transition from simple to malignant disease, instead of the sudden accession of a new and different kind of morbid action.

These warty growths, which exhibit the stubbornness and are apt to assume the destructiveness of malignant disease, are almost always met with in elderly persons. It is the best plan to extirpate them at once, where that can be done, and not to waste time in the application of caustic and other remedies, which are more likely to excite than to repress the growth, and which often hasten the enlargement of the absorbent glands. I remember regretting that I had treated with nitrate of silver a warty growth of this kind on the labium, in a woman, aged 60; for though the growth was without induration, presented the appearance of a simple affection, and was diminished in size for a time, yet it subsequently advanced more rapidly, the inguinal glands participated in the disease, ulceration took place, and proceeded as in ordinary cancer, and the patient died.

Perhaps it may be stated, as a general rule in these and in other affections of a similar kind, that the degree in which the natural structure of the part is altered, will be found to be proportionate to the malignancy of the disease. Thus, where the change consists simply in an outgrowth of the papillæ, with a thickening of their epithelial coats, after the manner of a wart, there the mass is slow in its increase, slow to extend to the stratum of tissue under the skin, slow to ulcerate, slow to make any impression upon the absorbent glands, and may be removed with great prospect of a complete cure. Secondly, where the warty disposition is less manifest, the alteration of structure being attended, rather with a destruction of the papillæ than their hypertrophy, and with the substitution of flattened cells, like those of epithelium, for the natural tissue of the cutis; there the malignant qualities are more evidently displayed, the mass increases more quickly, extending beneath the skin, involving the subcutaneous areolar tissue, muscular fibres, and even the bones; it ulcerates at an earlier period, the absorbent glands are more quickly affected, and we are not quite so free from apprehension of a return after removal. Still the disease is generally local, unattended with any constitutional indisposition, and is not likely to appear in distant parts. In the third class of cases, which comprises the scirrhous or encephaloid cancer of the skin, the morbid elements have still less relation to those naturally existing, the tissues are replaced, not by epithelial, but by cancer cells, or nuclei—that is to say, the new products do not exhibit a tendency to liken themselves to any one of the components of the skin, but assume the form, and are endowed with the endogenous productive qualities of cancer-cells; they breed others in their interior, instead of being themselves transformed into any kind of tissue. In these cases the disease commences, not with a wart, but with a tubercle, spreads quickly in all directions, ulcerates, attacks the absorbent glands, and is commonly associated, either as a primary or secondary affection, with cancer of some other organ; its removal, therefore, is attended with comparatively little hope of a permanent cure.

In May, 1846, I saw a cancerous affection of the

skin, of greater malignancy than we commonly witness when the disease originates in that situation. The patient was a light-complexioned, not unhealthy-looking woman, aged 30, suckling twins of two months old. On the right side of the scalp, over the tuber parietale, was a slightly excavated circular ulcer, an inch in diameter, with pale, granular surface, everted edge, and thin discharge. Its base was indurated, and somewhat adherent to the bone. Below the mastoid process was an indurated mass, as large as an orange, fixed to the surrounding parts, with an ulcerated excavation, extending nearly two inches into it. Both places were the seat of much darting pain. She said that the disease of the scalp had commenced three years previously, with a lump in the skin, which increased slowly; its advance, the ulceration, and the growth of the mass behind the ear, having been very rapid since her confinement. In May, 1850, the disease had progressed to a fearful extent; there was one great ulcerated cancerous mass, extending from the scapula to the vertex. The surface, flattended by pressure, for she generally lay with it upon a pillow, was pale red, coarsely granular, with fissures extending deeply into it. The discharge was copious, foul, and thin; the edge raised and everted. Near the vertex were two tubercles in the skin, cone-shaped and smooth, separate from the large ulcer, and from one another. She said that the disease had commenced in this way. I learnt that she died not long after.

The warty growths described by Mr. Cæsar Hawkins and others as cicatrices, more particularly in the cicatrices of burns, partake, I suppose, in a greater or less degree, of the nature of epithelial cancer, being for the most part intractable by ordinary means, and requiring extirpation for their cure. I have not happened to meet with any cases of this kind.*

Epithelial cancer attacks mucous surfaces, no less than the skin; sometimes commencing under the tongue, about the orifices of the salivary ducts, in the form of an indurated elevation of the membrane; it extends upon the jaw, and the under surface of the tongue, as in the case of the woman from whom I lately removed the mental portion of the jaw, the anterior and under surface of the tongue, and the parts intervening between the two. The patient recovered, and has not at present (six months after the operation) suffered any relapse.* In another woman the disease, commencing at the same spot, had involved the submental and submaxillary absorbent glands to too great an extent to admit of extirpation, and proved fatal within two years from its commencement. More commonly it attacks the tongue, beginning on one side, opposite the molar teeth, with a little thickening and induration of the part; the papillæ being sometimes prominent, so as to give it a warty appearance, ulceration soon follows, and extends into the substance of the organ. The pain or inconvenience attendant on the early stage of the disease not being great, we frequently do not see the patient till an excavated ulcer of considerable size has been formed, with a raised indurated base which extends probably to the side of the fauces, and involves the mucous membrane between the tongue and the jaw. The ulcer has a foul, greyish surface; and the induration is caused, as in other cases of the like kind, by the infiltration of a new product in the structure of the organ, and its substitution for the natural tissue. Examined microscopically, this new product is found to consist of epithelial cells, compressed and matted together, perhaps concentrically arranged, or elongated, and showing some tendency to split into fibres. In the further progress of the disease the palate and lower jaw, and submaxillary glands become involved, the movements of the tongue and jaw are impeded, deglutition is difficult, the flow of saliva increased, the breath fœtid, and the patient's condition is altogether very miserable during the short period of life which remains.

On the whole, there can be no doubt that, although it often is excited by a local source of irritation, such as a decayed tooth or stump, the epithelial cancer of the mucous membrane of the tongue and mouth, is far more actively malignant in its progress than when it affects the skin. Indeed, I think it exhibits in this situation as rapid and as determined destructiveness, with, perhaps, as great disposition to return after extirpation, as do the scirrhous and encephaloid cancers in other parts of the body; though it is not so likely to affect distant organs. Our hopes, therefore, of ultimate success from operative interference, are far less than in the treatment of the corresponding affection of the skin. Nevertheless, we may give the patient the benefit of the chance, when there is a fair probability of our being able to remove the entire mass. One woman from whom I excised a cancerous ulcer of the tongue returned to the hospital some months afterwards perfectly well, but I have not since heard of her. In another patient the disease reappeared soon after he left the hospital, and proceeded to a fatal termination. Before commencing the incision in such cases, it is necessary to pass a strong thread through the tip of the tongue, by means of which the organ can be drawn out of the mouth, and its movements controlled; then, if the part to be excised be seized with a vulsellum, the operation is

* I am indebted to my friend Mr. Reid, of Canterbury, for the following notes of a "Case of Warty Condition of the Cicatrix of a Burn," recently under his care:—E. A., aged 33, tall, and of spare habit, was admitted into the Kent and Canterbury Hospital, in August, 1849. During her childhood she had been burnt on the right arm, and side of the face and neck. The angle of the mouth was drawn down by the cicatrix of the neck and face, which was quite free from disease. The fore-arm was fixed at a very acute angle with the upper-arm, and a strong web of cicatrix-tissue extended between them as high as the middle of the arm; the hand was prone and flexed. The whole surface of the fore-arm, from the wrist to the elbow, indeed nearly the entire limit of the cicatrix, was covered with warty growths, closely set together, and having deep fissures and cracks between them, from which issued a very offensive, thin, ichorous discharge. Some of these warts were vascular, and were covered with the secretion, whilst others had a grey colour, and presented a more loosely fibrous texture; some few of these were partly detached. The patient said that occasionally masses of warty growth had loosened and fallen off. She suffered severely, and dreaded to have the arm uncovered. The arm bled at times when disturbed. Ten years before her admission she had noticed a wart on the scar of the fore-arm, which gradually increased and became ulcerated, yielding a thin discharge. The arm was amputated, and the stump healed by first intention, excepting at one point, and that to a doubtful degree: the disease did not extend beyond the integument of the arm.

* I have seen this patient since writing the above, and am fearful that there is some return of disease under the jaw; though the whole of the morbid mass was removed by the operation, and the wound healed kindly.

easily completed with a bistoury passed fairly behind the edge of the mass, and carried forwards through the substance of the tongue. Brisk hæmorrhage ensues from numerous vessels, some of which should be tied with the assistance of Assilini's forceps. The smaller vessels generally cease bleeding after a time if the patient be kept quiet in bed in a cool room, with the head raised and the mouth open. It is a good precaution to leave the thread in the tip of the tongue for two or three days.

Here are two specimens which present the ordinary characters of epithelial cancer of the bladder so closely that we may safely assume them to be of that nature, though they have not been submitted to the test of microscopical examination. In this one a large loose flocculent growth is seen sprouting into the bladder from the mucous membrane about the entrance of the left ureter; and there are several smaller growths of similar character upon the mucous membrane at the fundus. In the other specimen a soft vascular growth, as large as a hen's egg, is connected with the mucous membrane near the entrance of the left ureter. At the base it is associated with, and seems to be in great measure composed of, a prolongation of the membrane. At the free end it branches out into long loose flocculi, of a yellowish-white colour and soft structure, which were, in the recent state, besmeared with a substance like cream or soft cheese. The muscular coat of the bladder is much thickened. Both the muscular and mucous coats are extensively destroyed by ulceration at the fundus; and the peritoneum, and other coverings of the bladder, have yielded in this situation, so as to form a swelling, which was perceptible above the pubes during life. The patient, a gentleman, aged 55, had long suffered from frequent and painful micturition, with bloody urine, and had been sounded by several surgeons, his symptoms resembling those of calculus in many respects. He became pale and emaciated, suffering very greatly, and died exhausted. The most constant and characteristic symptom of this malignant disease of the bladder is the passage of blood by the urethra; the blood being not only intermixed with the urine, but being observed to pass in a small quantity, undiluted, or nearly so, after the urine has been evacuated. The patient will tell you that he has occasion to make water frequently; that the act is attended with pain at the end of the penis, about the perineum, and over the pubes; that the pain is most severe when the bladder is nearly empty; that the urine, generally turbid from admixture of mucus, pus, or blood, is sometimes nearly clear; and that, during the straining efforts which he is compelled to make after the bladder is empty, some pure blood often flows down the urethra, sometimes in very considerable quantities. There is scarcely any other disease in which this symptom occurs in a decided manner for any length of time; and when it is associated with a general cachectic condition the nature of the affection is tolerably certain. In cases of long-continued inflammation of the bladder in women you will now and then meet with soft vascular processes of the lining membrane projecting through the meatus, which bleed easily. These must not be mistaken for the disease in question. They are soft and smooth like common polypi, may be drawn out with a pair of forceps, and removed with safety by scissors or ligature; indeed, much benefit is sometimes experienced from their removal.

I cannot say whether the following case should be regarded as one of epithelial cancer. The growth presented many practical resemblances to that disease, though the subject was young:—A healthy-looking girl, aged 8, was brought to the hospital in August, 1844, with a red vascular excrescence, firm in structure, and granular or finely warty on the surface, projecting between the labia. It measured about an inch in diameter, and was attached by a pedicle as large as a goose-quill to the left side and lower part of the urethra, quite within the meatus. It had been observed for about a year, and had been removed by ligature, but had returned. Having drawn out the growth I passed a ligature round its neck as far back as possible. It sloughed away, and a little red warty growth sprung up at the situation of the ligature. To this I applied nitrate of silver, with some apparent benefit at first; but the growth soon increased in spite of that treatment, and the child ceased to attend at the hospital. I learnt afterwards from the mother that the growth attained a great size, bled frequently, and caused the death of the child about six months after she left the hospital.

This specimen affords an example of what appears to be epithelial cancer of the stomach. It is a large polypous tumour sprouting into the stomach near the cardiac orifice, which was almost blocked up by it. The surface is lobulated and granulated, like a cauliflower, and there is an ulcerated spot on the summit, leading to a cavity in the interior. The central part of the mass is firm, of grey colour, and striated. It is said to have been taken from a woman who had frequent discharges of blood by stool and by vomiting, with difficulty of swallowing.

LECTURE

ON THE

DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

BY DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE V.

Urine; Spinal Cord; Extremities; Anus; Skin.

URINE.—As it is difficult to collect the urine of little children, this liquid is less attended to in them than in adults. I will direct your attention only to a few of its *physical* qualities which I have observed it to

possess in the earliest infancy. In the first weeks and months after birth we find the urine of a healthy infant nearly colourless, and this quality persists nearly as long as they do not take substantial food. I observed, however, that the derangement of the health of an infant causes its urine to stain the linen in different ways, and after the spot is dry we perceive a colour more or less distinct. A *dirty whitish stain*, and a a little *stiffness* of that part of the linen, denoting the increased density of the urine, is frequently present in gastric disorders. A light *reddish* stain occurs in acute inflammations and inflammatory fevers, including the cruptives. A *reddish-brown* stain I observed sometimes in high degrees of acidity, which can be still better ascertained by litmus paper. A *yellow*, or *yellowish-green* stain is proportionally very rare at this age, as this colouration is proper to bilious derangement, particularly in icterus, *hematury*, and *pyury*, which are very rare in infants.

The urine of infants is in general superabundant of acid, consequently a moderate red colouration of the litmus paper by it is not significant. The lithic acid forms sometimes a *red gravel*, which is in general without bad consequence. The plurality of calculi of children are formed by lithate of ammonia. The evacuation of urine is sometimes impeded by, or accompanied with, *spasm of the neck of the bladder*—dysury. In this case the child cries most violently, the urine commences to flow drop by drop, then it runs freely, and the child ceases to cry. In this case we inquire if the urine stains the linen; as in the case that this liquid is quite colourless, we infer the spasm to be purely nervous. If there is some coloured or dirty stain, the spasm probably depends upon gastric derangement, and a consequent irritative quality of the urine. Dysury from stone does not occur in the earliest period of infancy; and if a child presents its probable symptoms, we ascertain the case by sounding.

The spine.—The osseous canal of the spine is frequently altered by disease in children, but with the exception of spina bifida, the affections of the vertebræ seldom do occur in the first year of life.

Spina bifida is soon detected after birth, by a round, oval, or pyriform tumour, covered with a very thin sheath of skin, which sometimes is even more or less deficient, most commonly on the lower half of the spine. A certain degree of paralysis of the lower extremities, rectum, and bladder, is generally connected with this deficient formation.

Most of these patients die very soon. A boy, 13 years old, was the eldest which I saw with this imperfection of organic development. Mr. Whitehead, of Manchester, had lately a case in a lady above 20 years old, and he succeeded in curing it by the double ligature.

The *adynamic*, the *rachitic*, and the *carious* curvatures of the spine, seldom commence before the fifteenth month. I call the lateral curvature (which by others is termed the sigmoid) adynamic, as there is no affection of the texture of the bones, but simple deviation from the normal line, from disproportional development of the muscles which are acting upon the spine, or by long-continued asymmetric positions, occurring in both instances, as a matter of preference in weak or delicate constitutions. This curvature in general extends over a considerable length of the spine, in a gradual line, laterally. The rachitic is connected with an alteration and swelling of the spongious part of the vertebræ, and forms commonly a curve backwards, sometimes anteriorly, that is, into the chest; this curve is more sudden and salient than the former, but still extends over a good length of the spine, easily recognizable by the general habit of the child. The caries of vertebræ is the most insidious of all, and the most dangerous to life. It develops itself in some cases, internally, to a certain extent, before we are struck by external symptoms. Caries is almost always limited to the spongy part of one or two, seldom of three vertebræ; consequently, if these parts are destroyed, the next vertebræ approach each other, whilst the corresponding spinous processes necessarily protrude in a more or less angular form backwards; consequently the line of this curve is not so gradual as that of both the former, and much more limited to a small extent of the spine. In this case we observe also paralysis, as the consequence of pressure exerted by the altered bones and the purulent liquid upon the cord. This symptom is frequently the first, before even the appearance of an external deviation, and we must be aware of this.

Slight degrees of lateral curvature we detect by close inspection, giving to the child an upright position on the arm of its mother; if then we cause the trunk to be anteriorly bent, this curvature will disappear by the extension which, by this posture, acts upon the spine, and will reappear if again the child sits upright; but if the curvature is more severe, or connected with an organic change of vertebral texture, then it does not disappear by bending the trunk. On the contrary, slight degrees of curvature, caused by caries, will just be the more perceptible if we bend the trunk anteriorly.

Affections of the spinal cord and its envelopes.—Hæmorrhage or inflammation are very rare in little children. There is only one *local* symptom in cases of spinal inflammation, this is the constant straight dorsal position observed by the child, and expressions of pain, if we move it, or bend the spine; fever, vomiting, stiffness of the limbs at first, and paralysis after transudation has taken place; but as these are not local symptoms, but the result of troubled innervation, they do not belong to our present task. I seldom could perceive, or even suspect, spinal meningitis, before the stage of transudation, which, if acute and considerable, almost always, and very soon, causes death to tender children.

The *extremities*, we consider in their proportional development and muscular strength. Thin and flabby limbs, with a large skull and large abdomen, is a scrofulous or rachitic symptom. Habitual strength or weakness of the legs, in proportion to the age of the child, show a good or a weak constitution. Constant disorders in the mobility, without local changes in the joints, refer to affections of the brain or of the spinal cord.

But these affections may possibly be only functionally nervous; they are not always connected with organic changes in the nervous centres. *Contracture* is sometimes congenital, but more commonly consecutive to nervous diseases, either with organic alteration, or purely nervous. This latter kind, which I have ascertained, as well as French physicians, by dissection, is termed by the latter (Rilliet and Barthez,) the *essential contracture,* which I have seen as the consequence of convulsions, purely nervous. Most commonly we see this state of permanent contracture of the flexors, connected with only a degree of paralytic weakness of the affected extremity or extremities. Complete paralysis, on the contrary, of the flexors as well as extensors, is almost always the result of transudation or softening. If this takes place in one hemisphere of the brain, then the paralysis extends over the whole length of the opposite half of the body, from the muscles of the face to those of the foot.

The *anus,* soon after birth, offers an abnormity which we call *atresia ani*, or imperforate anus, sometimes without the least opening, at other times there is a small opening, leading to the rectum. I have seen no more than eight similar cases in the whole extent of my practice. The *prolapsus ani*, a frequent consequence of dysentery in children, shows us a part of the mucous membrane of the rectum. As there is always a degree of strangulation caused by the sphincter, a considerable passive congestion is necessarily present in the prolapsed mucous membrane; but sometimes we perceive a swollen surface, with much granulous appearance, the follicles swollen or ulcerated, which are all symptoms of inflammation. On the contrary, redness at the *orificium ani*, with erosions or ulceration, is most commonly the consequence of the irritating quality of discharge, or of uncleanness, and is seldom dependent on pure intestinal inflammation. I have been satisfied that the latter circumstances gives sometimes rise even to luxuriations like flat tubercles, independent of syphilis; and these luxuriations at the *orificium* are frequently surrounded by eczematous eruptions and ulcerations, extending over the contiguous parts of the thighs; this is in particular the case in scrofulous children abandoned to uncleanness. I have succeeded in curing hundreds of similar cases without antiphlogistic means.

The skin.—You need not to be referred in this place to the various chronic and acute eruptions of the skin; these, and ulcerations, or any other local affections of the derma, are easily recognizable, and have their more or less clear signification, local and constitutional. The *red* fœtal colouration of the skin sometimes persists for some weeks after birth; and I remember a case where a practitioner took it for erysipelas. *Cyanosis*, if the consequence of the abnormal persistence of the fœtal blood-communications, gets its full signification by auscultating, in which case a bellows murmur will never fail. But I have seen cases of cyanosis in children dependent upon gastric disorder, or rather derangement in the portal system. *Yellow* colouration, if primary, denotes bilious derangement, but frequently after erysipelas or erythema follows a degree of icterus during the course of recovery, which yellowness is without signification. *Paleness* of the skin, with proportional want of redness of the mucous membrane of the eyelids, the tongue, and lips, signifies chlorosis, which I met with in some cases even about the second year of age, and ascertained it by auscultation and the presence of the carotid *souffle.*

The *temperature* of the skin, dryness, or perspiring state, heat or coolness of it, are of the same signification as in adults, only that there is more variability of temperature in children. The high degree of dry and burning skin, proper to typhoid or putrid fevers, I never met with in the first years of childhood.

Next we shall speak of the pulse and then of some other symptoms.

CASES IN MIDWIFERY,

WITH REMARKS.*

By THOMAS RADFORD, M.D., F.R.C.P., Edin., &c., &c., &c.

Consulting Physician to the Manchester and Salford Lying-in Hospital.

The following case was most kindly and liberally given to me by James Braid, Esq., M.R.C.S., Edin., C.M.W.S., &c. &c., for the purpose of publication:—

Case VI.

Cæsarean Section.—(*Unsuccessful.*)

"About one o'clock, P.M., on the 15th of June, 1847, I was requested to go to Wilmslow, in Cheshire, to perform the Cæsarean section in the case of a poor woman named Mrs. Toft, who had been in labour since early on the morning of the 12th, that was three days and a half, and for whom the surgeons in attendance considered there was no hope of relief otherwise than by such operation. I consequently started by the first railway train, accompanied by my son, and arrived at the house of the patient about half-past two o'clock. The patient was said to be about 30 years of age, and had been married twenty-one months. She became pregnant shortly after marriage, but aborted at the third month. On the present occasion she had arrived at the full term of utero-gestation *before calling for professional aid*, which indeed she did only *after* labour had commenced, which was early on the morning of the 12th. Mr. Mayson, surgeon, of Wilmslow, had attended her alone from Saturday morning till Monday morning, when he had Mr. Dean, surgeon, of the same place, associated with him, who continued his attendance, along with Mr. Mayson, up to the period when Mr. Dean came to request my aid. The patient had always been of a feeble constitution, with fair complexion, but now she was excessively pale and exhausted, and was much disfigured by a large bronchocele. Her

* Continued from page 428.

pulse was very rapid and feeble. On examination, the first object which attracted attention was the arm of a well-developed child protruding from the vagina, proving it to be a case of shoulder presentation. The bones of the outlet of the pelvis were so crushed together that there was scarcely room for one finger to pass by the side of the protruding arm, so as to make an examination. The arm being pushed up, I ascertained that the rami of the pubes were so closely approximated that a finger placed edgeways could not reach the symphysis pubis; and the tubera ischii were only about an inch apart, for there was no point where two fingers placed side by side could pass when directed transversely. Indeed, owing to the close approximation of the rami pubis, tubera ischii, and os coccygis, there was barely room sufficient to permit two fingers to pass the outlet of the pelvis in the antero-posterior direction. Owing to the shallowness of the pelvis, however, which must have been originally of small dimensions, I was the more readily enabled to reach and determine the dimensions of the brim. I ascertained that there was not as much available space in the antero-posterior direction as to permit the points of two fingers, laid side by side, to pass the brim of the pelvis, excepting about half an inch exactly opposite the symphysis pubis, and there the fingers had barely room to pass. Beyond this, on either side, there appeared to be little more than an inch of available space in the antero-posterior direction. The transverse diameter might exceed three inches, but then it was crescentic in form, which, of course, made it completely unavailable for delivery. My son having also made an examination of the patient, and made a similar estimate of the relative position of the bones of the pelvis at the brim and outlet, which were, moreover, firm and unyielding, we had no difficulty, in consultation with the other two surgeons, Mr. Mayson and Mr. Dean, in arriving at the conclusion that the woman must die, undelivered, if we did not instantly resort to the Cæsarean section. With such deformity as existed here in the pelvic bones it must have been all but impossible to have broken down and extracted a fully-developed child, (which from the protruding arm this evidently was), even in a vigorous patient; but in a feeble woman like the one in question, exhausted to the last degree by the length of time she had been in labour, and the violence and acute suffering which she experienced from the pains, even up to the period when we were with her, it would have been perfectly futile and absurd to have made any attempt of the sort. The extreme violence and excruciating agony which the patient was suffering from the pains rendered it the more desirable that the operation should not be unnecessarily delayed; and we, therefore, stated our views of the whole bearings of the case fully and fairly to the friends, and obtained their consent, and subsequently the patient's also, when I proceeded to perform the operation in the usual manner, at three o'clock. I deem it quite unnecessary to occupy your time by giving any details of the operation, for, although a formidable and a most important one, and one which ought only to be performed from the necessity of the case, still, *quasi* a surgical operation, it involves comparatively little difficulty to those who are well acquainted with the anatomy of the parts, and are in the frequent habit of operating. A very few minutes sufficed to make the necessary incisions and to extract the child, the placenta and the coagula were found in the uterus. All this and the stitching, dressing, and replacing the patient in bed, certainly did not exceed ten minutes; and the whole pain sustained by the patient in consequence of the operation, did not appear much to exceed a single pain, such as she had in our presence, from the throes of nature, before we proposed the operation.

"The infant was large, and well developed, but was dead, obviously from *previous detachment of the placenta*, for it was found quite detached, and surrounded by coagula, which at once accounted for the exsanguine appearance of the mother, as well as for the death of the child. There had been very little coloured discharge *per vaginam*, the egress having been completely closed by the shoulder of the child being impacted into the brim of the pelvis. Very little blood was lost by the incisions made during the operation, and very little passed *per vaginam*, subsequently. After the operation the patient seemed to suffer no more pain, but she passed quietly away, from exhaustion, five hours and a half after the operation.

"On the 17th I went over, accompanied by my son and another medical friend, for the purpose of having a *post-mortem*. Mr. Dean was also with us. We had almost been too late, as the company had assembled before our arrival for the purpose of interring the body; they consented to postpone it a very short time, to allow us to make an inspection, but we were necessarily compelled to be very circumspect, as we were closely watched, and were thus prevented the opportunity of possessing ourselves of the pelvis; however, I had used the precaution of taking some plaster of Paris with us, and thus we were enabled to take an accurate model of the inlet of the pelvis; from this it was satisfactory to find that the estimate made of the brim of the pelvis previous to undertaking the operation had been very correct, as the following measurements of the cast prove:—The diameter of the brim of the pelvis, from the symphysis pubis to the lumbar vertebra, was one inch and three-eighths, and beyond that on the left side it abruptly diminished to nine-eighths of an inch and from that to half an inch, and on the right side from an inch and a quarter to an inch. The transverse diameter from right to left was three inches and a half, but of this there were not more than two inches, which would admit a ball to pass which exceeded an inch in diameter. But, as already stated, the brim had assumed a crescentic form, so that when two straight parallel lines were drawn across the pelvis, they only showed two inches by one inch as the largest available space. Under these circumstances, therefore, it is quite obvious that delivery, by mutilation of the infant, could not have been undertaken with an hope of success, at any stage of the labour, however vigorous the patient might have been; how much less so, then, with such a con-

stitution as we had here to encounter, and with a shoulder presentation, too? The cavity of the pelvis was so small as not to admit a body greater than a lemon. At the left side and anterior part of the fundus uteri the walls of the uterus were fully an inch and a half in thickness, whilst a considerable portion on the posterior and right side was attenuated in an extreme degree, so that from this circumstance, and the violent and cutting character of the pains witnessed by us, had she been left a short time longer untouched, in all probability rupture of the uterus, and death, would have been the result. Very little blood had escaped *per vaginam* subsequently to the operation, and there was only a small clot found within the cavity of the uterus. Here, then, is a case which, I think, fully justifies the Cæsarean section, for no medical man had been consulted until the woman *was in labour at the full term of utero-gestation*, and with physical attributes which rendered it impossible for her to be delivered in any other manner than by the Cæsarean section. The only cause of regret is, that this had not been undertaken immediately after labour commenced, for in that case there is every reason to believe that the life of the infant would have been spared, with a tolerable chance of safety for the mother also. This alternative had been proposed to the patient before I was sent for, but she obstinately held out against submitting to any such operation. I consider it but an act of justice to Mr. Dean and Mr. Mayson to record this fact, and that it took some management on my own part to obtain her consent at last. Although the operation failed to save the life of mother or child, still it relieved her of suffering for the last five hours and a half of her life, and her friends the pain of hearing her piercing screams, and witnessing the agonizing throes which accompanied the unavailing efforts of nature to relieve her from her perilous condition."

Dr. Radford's Remarks.

Malacosteon doubtless was the disease which caused the distortion of the pelvis of this poor creature. There are no data whereby to judge when its ravages on the bones were commenced. Some of the contingent circumstances which happened, clearly prove the truth of those statements I made a short time ago (*vide Provincial Medical and Surgical Journal*, No. 7, April, 1851, page 175. It was her *first labour*; and we have no evidence to show that any symptoms existed either *before or during her pregnancy*, to induce her to place herself under medical treatment. The obstetrician was *completely ignorant of the physical and organic* condition of the *pelvis* until *after labour* had commenced. It is, then, indisputably true, that no other operation but the Cæsarean could possibly or safely be performed for her delivery. The great mischief of procrastinating the operation is emphatically proved by the result. Several serious evils arising from the protracted labour are noticed by Mr. Braid. The death of the infant was undoubtedly produced by it, and most likely that of the mother. The internal flooding, the complete separation of the placenta, and the attenuated state of one portion of the structure of the uterus—which no doubt would have ended in its rupture—are solely to be attributed to delay.

In Cases I. and V. I have mentioned that violent irregular uterine contraction happened during the extraction of the infant, which I stated depended on the partial or complete detachment of the placenta. In the foregoing case, however, nothing of the kind took place, although this organ was lying loose in the uterus. Did the internal bleeding (which was so great as to bleach the general surface) act on the uterine tissue, and so influence its contractility? Was the absence of this spasm (when its supposed cause was present) owing to the extreme degree of attenuation of the uterine tissue ?

CASES IN MIDWIFERY.

By J. KENWORTHY, M.R.C.S., Manchester.

Read at the Nineteenth Anniversary Meeting, held at Brighton, August 13, 1851.

The following extracts from my midwifery notes being cases of uterine hæmorrhage, in connection with placenta prævia, may possibly be interesting to some of the members of the Association; some of them occurred many years since, and the *minutiæ* are not all recorded, for eighteen years of the time in which the earliest cases happened I was a good deal occupied in the hospital wards of the workhouse, but did not meet with any case of importance of this description in that class of practice.

Case 1.—March 7th, 1819.—Mrs. B. One edge of the placenta presented. Pressure of the fœtal head lessened the hæmorrhage, and the labour terminated in the natural way. She was faint after it was over, and seventy drops of laudanum, with a little brandy, were administered, in tea. The mother and child both did well.

Case 2.—January 30th, 1821.—Mrs. W. Was seven months advanced; there was hæmorrhage a week previously, which subsided under the use of acids; quiet, horizontal position, and cold externally applied. At ten P.M. on the 29th hæmorrhage returned. I found the placenta presenting, but the cervix uteri would not admit my finger through it, being thick and unyielding. The same means as before, with the addition of ten drops of tincture of opium every hour There was no uterine action. I enjoined perfect quiet, a free admission of air, and to drink cold lemonade. At five o'clock on the morning of the 30th no natural change; the hæmorrhage was less. At 10 A.M. the bleeding was much increased, and she was faint. The cervix was more yielding, and partly dilated. I thought it wrong to delay, and introduced my hand very quietly round the placenta, broke the membranes, and delivered by the feet. There was very little uterine action throughout. She was much

overjoyed, and the hæmorrhage ceased. An hour after delivery faintness came on, and gradually increased, and in a quarter of an hour more she died. On inspection all was found natural. No accident had happened to the cervix. The child was living.

Case 3.—October 26th, 1823.—Mrs. L. Seven months advanced. Hæmorrhage large. I introduced my hand round the placenta, when the cervix was dilated the size of half a crown. The child was dead. The mother safe.

Case 4.—June 27th, 1826.—Mrs. B. I found her swimming in blood and water, without uterine action. It was evidently wrong to delay. I passed my hand quietly round the placenta, and found the child lying across the pelvis, with the left arm presenting. I delivered it, and the flooding ceased. The placenta was expelled by the succeeding pain. The mother and child have both done well.

Case 5.—July 23rd, 1834.—Mrs. S. One half the placenta presented towards the right ilium. She had hæmorrhage two months before, which subsided under the use of ergot. She was nearly eight months advanced; hæmorrhage in gushes, very rapid; uterus lax, and its action feeble; the cervix nearly obliterated. I gave the ergot, and immediately delivered the child (the eighth); repeated the ergot every fifteen minutes after delivering the fœtus, and the hæmorrhage abated. There was a fold of the funis before the child's head; the circulation through it was interrupted perhaps a quarter of an hour, and life appeared extinct; the warm bath, inflation of the chest, friction, &c., were used, and the vital spark was roused in about half an hour. The mother remained faint several hours, and required powerful stimulants to rouse her. Both have since done well.

Case 6.—April 11th, 1841.—Mrs. W. This case was four months advanced. The placenta presented wholely, and the hæmorrhage was rapid; the cervix dilated, so that I could pass my hand, and I delivered the fœtus without delay; separated the placenta, and left it. Gave Tinct. Opii., m. lxxx., and the next pain it came away. She was a little faintish. Tinct. Opii., m. xl., were again administered, and in an hour or a little more all was well.

Case 7.—September 3rd, 1842.—Mrs. T. This case was nearly matured, and the placenta was completely over the cervix. The hæmorrhage was very rapid; dilatation the size of half a crown. I passed my hand slowly round the placenta, brought down the feet, and waited an hour or more. She was faint and debilitated by repeated floodings during the pregnancy. My arm was a plug. Gave her brandy in tea, and immediately before taking away the fœtus, half a drachm of ergot was given in substance. The child possessed but little vitality, and I did not divide the funis for more than an hour, during which time the circulation was maternal. The ergot was repeated after the birth of the child, and I left them both pretty well in two hours and a half.

Case 8.—December 11th, 1850.—Mrs. O. Was 36 years old; her fifth child. One half the placenta presented towards the left ilium; saw her first at 11 A.M.; hæmorrhage rapid, without pain; no dilatation of the cervix. She was seven months advanced. I gave her Opium and Tinct. Ferri Sesquichloridi once an hour, and applied cold wet cloths to the vulva and pubes. At three P.M. I was summoned in haste. Hæmorrhage had been less, but had returned rapidly; fainting; incoherent in her expressions; hardly conscious; moaning; pulse fluttering, and almost imperceptible; scarcely any uterine action; dilatation of the cervix now the size of a penny, perhaps the effect of excessive hæmorrhage. I thought it unsafe to delay, and introduced my hand very slowly round the placenta, grasped the child's feet, and after waiting an hour, got some brandy and opium into her stomach in tea. She took four drachms of laudanum during the first twenty minutes. A feeble rallying of the pulse was now apparent, and I drew away the child very quietly a little after five P.M. I separated the placenta immediately, and left it. Friction was used to the extremities; and by grasping and irritating the external parietes of the abdomen in half an hour or more there was a slight uterine effort manifested, during which I took away the placenta. She had tea, with brandy and opium, given to her repeatedly; and I left her in a promising way a little after six o'clock. The hæmorrhage ceased immediately after the separation of the placenta; but whether from the effect of separation, or from its acting as a plug, is to me a question; I am inclined to think the latter. The child had been dead a week, and there was scarcely any uterine action throughout the case. She took five drachms of tincture of opium during two hours. I saw her in the evening; she was sensible, and somewhat rallied, and eventually recovered, but remained long debilitated.

Case 9.—February 18th, 1851.—Mrs. B. Was 38 years old, and her sixth child. One edge of the placenta presented towards the left ilium. There had been occasional hæmorrhage during two months or more; the last ten or twelve days there were several gushes. I advised the recumbent posture, gave her digitalis and sulphuric acid in infusion of roses, applying cold cloths occasionally. No uterine action until the 18th. At three A.M. the cervix was dilated to the size of a crown; coagula passing, and some evidence of alarm in her countenance. The liquor amnii was discharged, and the child's head presented, squeezing the placenta to the left ilium, and moderating the bleeding. The uterine effort was feeble. I turned the child, and delivered it slowly a little before five A.M., immediately before which she took Tinct. Opii, m. xl. The pressure now being taken off the placenta there was a rapid hæmorrhage. I separated it from its attachment, left it as a plug, and the hæmorrhage ceased. All has since proceeded favourably.

This case was six months and a half advanced. The child was living, and died in 28 hours.

We have means now within our power, with which in former years we were unacquainted,—the ergot for instance; but perhaps there may have been unfortunate results from incautious use of it; and very satisfactory effects in many cases may, I think, be obtained more safely from opium. Mrs. O., in December last, is an example.

June 25, 1851.

A CASE OF

NON-UNION OF FRACTURE OF BOTH BONES OF THE LEG, OF EIGHTEEN WEEKS' STANDING, SUCCESSFULLY TREATED BY MERCURY.

By R. THURSFIELD, Esq., M.R.C.S., Broseley.
SENIOR-SURGEON TO IRONBRIDGE DISPENSARY.

In the month of August, 1847, I was asked to see an old patient of mine, aged 42, who had twice suffered severely from acute rheumatism. I learnt from her that about eighteen weeks before, she had, on returning from an evening visit to her sister, slipped in crossing a rough road, and fractured both bones of the leg just above the ankle. She was not far from her sister's house, and a surgeon was soon in attendance. Her leg was placed on a pillow and the usual means employed; but in about six weeks after the accident it was ascertained that no bony union had taken place. Upon further advice starch bandages were applied; but no benefit resulted. On examining the leg I found it greatly swollen, shorter by an inch at least than the other, with a good deal of deformity, greatly increased by any attempt at standing upon it, and the least motion at the point of fracture. She had greatly increased in bulk during the confinement she had undergone, but considered herself in good health.

I was a good deal puzzled what plan to pursue with the best chance of successfully relieving her, for I had never had to treat such a case before, and the uncertain results in the experience of others were anything but encouraging. In thinking over the case I remembered that the late Mr. Tyrrell had said mercury in his hands had proved at least as efficacious as any other plan he had tried; and I made up my mind to use it, because the peculiarly irritable state of the patient put sawing off the ends of the bone, seton, or any other surgical means quite out of the question, and most others seemed to have been fairly tried. I therefore procured two very strong gutta percha splints, which reached from rather above the knee to the bottom of the foot, and having, on the 18th, soaked them in boiling water, I made a complete cast of the leg by passing a tight roller over them and allowing them to cool. Having brought the ends of the bones as nearly into apposition as I could, and covered the parts with mercurial ointment, &c., after the plan recommended by Mr. John Scott, I applied the splint, and bound all together with a long elastic bandage. I confined her to bed, and tied the leg on a pillow, giving her five grains of blue pill night and morning. No perceptible effect from the mercury took place until she had taken sixteen pills, when suddenly violent ptyalism set in, which lasted a fortnight. On the 7th of October the bandages, &c., were removed, as they had become loose from the reduced size of the leg, and a great improvement was found to have taken place The leg was longer, the deformity less, and the motion at the fracture scarcely perceptible. Greatly encouraged by such a state of things, I renewed the applications exactly as at first, and allowed her to use a sofa during the day. In about three weeks I again tightened the roller, and in another month removed everything from the leg, and found the fracture perfectly united and firm. For a month after this time she had the leg well rubbed night and morning with camphorated oil, to get rid of the remaining œdema, wearing a roller and one splint during the day, to protect the leg if she should chance to slip in walking. In six months she could walk well two or three miles, and is now as active as most women of her age, the broken leg being as useful as the other.

CASES IN PRIVATE PRACTICE.

By JAMES KITSELL, Esq., Droitwich.

Read at the Nineteenth Anniversary Meeting, held at Brighton, August, 1851.

Case I.—Case of Retention of Urine, with False Passage, and Paralysis of Bladder.

In March, 1850, I was requested to attend J. P., a farmer of independent means, who had laboured under retention of urine at intervals for nearly a week. On my arrival, the medical man in attendance, "although not qualified," had made numerous attempts, unsuccessfully, to introduce the catheter; a medical gentleman from Birmingham having also visited the case twice, and succeeded in introducing the catheter, though not without great loss of blood, owing in some measure to the unskilful use of the instrument, before his arrival, and the formation of a false passage, which, considering the age of the patient, (69,) who was of impaired constitution, rendered the case very serious. On my arrival I learnt from the patient that he had long been subject to dribbling of urine, frequent inclination to void it, and other symptoms indicative, at his period of life, of prostatic enlargement, of which I satisfied myself on examination *per rectum*. On introducing the catheter it readily entered the false passages, and no little manœuvring was required to conduct it into the bladder. The instrument being of No. 5 size, passed with difficulty through the constricted prostatic portion of the urethra, when about two pints of urine were

drawn off, the size of the catheter being gradually increased until No. 12 could be passed with little difficulty. Owing to the over-distended state of the bladder at the onset of the case, when more than three pints of urine were removed, this viscus became so paralyzed, that nearly seven weeks elapsed before it evinced any symptoms of resuming its tone, during which time the patient felt not the slightest inclination to void his urine, although a pint or more would occasionally be collected, owing to the patient's residence being a distance of nearly five miles, and my having to visit him twice daily. The treatment consisted in the internal and external use of strychnia, iodide of potassium, with Plummer's pill and conium at bed-time, and keeping the catheter occasionally in the bladder through the night.

Suffice it to state that the patient recovered, and voided his urine better than he had done for some years, until he experienced a slight return about fifteen months after, owing, as I suspect, to some excitement of the genital organs, from causes which I need not here attempt to explain, which was easily relieved by timely aid.

I have merely reported this case to show how much relief can be afforded in a case which appeared for some time nearly hopeless, since there was great reason to fear that the tone of the bladder should be irrecoverably lost.

Case II.—Extensive Fracture of the Ribs, with Emphysema.

A porter, employed at the Droitwich station of the railway, was proceeding to fasten the connecting chain of a luggage train, which contained thirty-six tons behind and sixteen in front of him, when, on the train being suddenly moved, in his endeavour to escape, he became pinned between the beam ends, (if I may so term them,) there being no spring buffers as in passenger trains. Being frightfully crushed, he was brought to Droitwich, (a distance of a mile and a half,) in the omnibus, in a state of collapse, which lasted for some time, and from which it was not expected that he would rally; however, under the cautious use of diffusible stimuli, he slowly rallied, a quantity of blood and frothy saliva issuing from his mouth. As reaction proceeded, acute inflammation of the lung succeeded, the 2nd, 3rd, 4th, 5th, and 6th ribs on the left side being sadly fractured in their sternal and dorsal aspects. As the power of respiration increased, a tumour, larger than a distended sheep's bladder, occupied the seat of injury over the lung, the laceration in which must have been considerable, since this tumour appeared to become directly inflated at each respiration, alternately rising and falling with remarkable impulse, until more than one-half the body was inflated; several punctures having been made into the over-distended cellular membrane, and a bandage applied as soon as practicable, with copious depletion, the patient being of stout robust constitution, considerable difficulty was experienced with the rising end of the 2nd rib, which from its position could not be readily compressed with a bandage, to obviate which difficulty I employed a spring truss, on Salmon and Ody's principle, which, passing over the shoulder, the requisite compression was effected by the anterior pad, and the fractured ends thus kept in apposition. Considerable quantities of pus streaked with blood were expectorated from this extensive wound in the lung, but fortunately the patient recovered, and at the end of six weeks resumed his employment, which he has continued for very many months, apparently as well as before the accident. The crepitus during the act of respiration was audible at a considerable distance from the patient.

Case III.—Instantaneous Relief in a Case of Croup from Fright.

M. D., aged 9 years, was suddenly attacked with symptoms of acute croup, the peculiar cough, difficult respiration, with the head thrown back, and threatening symptoms of suffocation being apparent, it was deemed advisable to abstract blood as usual, when the child's great objection to the application of leeches threw her into a regular paroxysm of rage and fright, which, producing a regular and copious perspiration, all the symptoms immediately vanished, no return being experienced. An equal objection or dread of the lancet was evinced on an attempt being made to open the jugular vein. This case merely shows what good can be effected through the medium of the skin under peculiar circumstances; the shock given to the system, in addition to the copious perspiration, must have had its share in reducing the vascular and nervous influence, and thus removing a complaint which, under ordinary treatment, might have proved dangerous or fatal.

Case IV.—Diabetes in an Infant.

It will appear strange that after the case of hydrocephalus in one of my own children another still more peculiar and interesting—nay unparalleled, should occur in my own domestic circle, viz., diabetes; the subject being a male child now nearly eight months old, who, although born plump and apparently healthy, began to manifest, "a few days after birth," symptoms of diabetes, the quantity of urine voided being enormous, and truly characterized as *diabetes mellitus*, the *smell and colour of honey* being so strong as first of all to attract the attention of the mother and nurse, who, without any idea of the complaint, observed to me that the napkins smelt fragrant like honey, which remark, in fact, led me to the case, the nature of which was now (about a fortnight after birth) too evident to be mistaken; the usual concomitant symptoms being strongly developed, viz.,—a hot dry skin, voracious appetite, constipation of the bowels, extreme emaciation; in fact, the little patient may be termed a living skeleton. It is really wonderful that he should have survived so long in this state, having been almost in *statu quo* for nearly six months; the cranial bones being nearly as moveable as when first born. Although troubled with cough, apparently the result of repeated catarrhal attacks, there is no decided pulmonic disease,

as he cries remarkably strong, nor is there any hectic tendency apparent in the countenance by night or day, the catarrhal attacks being induced, most probably, by the change of temperature to which the body is exposed, consequent on the frequent change of napkins by night and day, (which average about one per hour,) completely soaked. It is remarkable that not the slightest acidity has been traceable in this case, as connected with the stomach.

The food consists partly of the breast-milk and partly of panada, or bread boiled in water to the consistence of thick custard, sucked from the glass feeding-bottle with India-rubber teat, which food the child unfortunately refuses unless sweetened. As regards the treatment in so young a subject, great disadvantage prevails, inasmuch as anything in the form of medicine is speedily rejected, and occasionally the food, apparently from over-distension, the result of that insatiable desire on the part of the stomach to become over-loaded; and when not satisfied in this way his cries are distressing. Milk food, beef-tea, and such like, are also rejected, no attempt having at present been made to convey it by means of enemata. The preparations of iron, the Ferri Sesquicarb, and Tinct. Ferri Sesquichloridi, could only be administered at intervals, when diarrhœa occasionally, although rarely, occurred, which medicines in cases of a cachectic tendency, and with an impoverished state of the blood, deprived of its carbonate of iron, I have found from experience most beneficial; an occasional dose of Hydrarg. cum Cretâ, or calomel, being sometimes required, owing to the deficiency of bile in the alvine excretions; opiates being sometimes needed to procure rest. Dover's powders, with diaphoretic doses of Antim. Tartarizatum, appeared most suitable; but the stupefaction consequent on any medicine of this kind, in careful doses, soon prohibited their administration. Cod-liver oil was tried, with a view to its nutrient property, but was soon rejected. As this disease has been considered by authors to depend on a shattered state of the constitution, and peculiar to spirit drinkers, or to an excess of vegetable diet, and in the decline of life, this case becomes at once instructive and interesting, inasmuch as no such cause could have influenced the subject of this report. In conclusion, I may observe that the urine, although not diminished in quantity, has lost, in a great measure, its melliferous property, being now of a more cadaverous or putrescent smell, a similar odour being observable in the alvine excretions. I have not tested the urine with reference to any albuminous property which it may possess, nor have I yet tried the phosphoric acid.

Remarks on the Present Poor-Law.

Mr. Kitsell then called the attention of the meeting to the present inadequate remuneration of the Poor-Law medical staff, who are still not half paid in their annual salary, besides having much to contend with in reference to any claim they may have for extras, which are but partially provided for in the Poor-Law [illegible] for instance, in the scale of allowances for fractures, dislocations, and midwifery, no allowance is made by the guardians for fractures of the clavicle, jaw, ossa nasi, &c. The guardians will not allow for fractures of the clavicle, although strictly a portion of the upper extremity, because the term arm is used in the printed form of allowances. And in fractured ribs, even with emphysema, the fee has been refused, because they are not specified. And in cases of bad wounds, scalds, burns, &c., which must of necessity accasionally fall into the hands of the union surgeon, no provision is made. In cases of midwifery, when the maximum fee of £2 is demanded for the operation of turning in placenta, arm, or other preternatural presentations, as also in forceps and other instrumental cases, the medical officer has, (after inquiries made by the relieving officer of the nurse and patient, anything but pleasant or delicate,) to explain the particulars of his operation and proceeding to the Board, who ultimately decide (for want of knowing better) that such a case is not entitled to the maximum fee, and reduce it to 10s., the medical officer being lucky if he gets occasionally £1 for an operation which rescues his patient from the jaws of death, independently of riding some forty or fifty miles in after-attendance on some of those cases. No allowance at all being made in cases of abortion or premature labour, unless the pregnancy be sufficiently advanced to admit of the child's being born alive. Surely there needs reform in this as in other departments of Poor-Law medical remuneration. In cases of abortion much more trouble, anxiety, and attendance are required than in ordinary cases at the full period, especially when these cases happen in the country. It is much to be regretted that members of an honourable and enlightened profession should be subject to the caprice and decision of Boards of Guardians, who are composed of good, bad, and indifferent, quite incompent to judge of medical matters, or the remuneration connected therewith.

Result of the Case of Hydrocephalus.

Mr. Kitsell also stated that his child, on whom he operated for hydrocephalus, in April, 1849, reported at the Seventeenth Anniversary Meeting, (*Provincial Journal*, August 8th, 1846, page 431) continues to enjoy uninterrupted good health.

DR. THOMSON'S INVALID LIFTER.

Exhibited at the Anniversary Meeting, held at Brighton.

This apparatus, of which the following wood-cut gives an excellent representation, has been constructed for the purpose of raising and removing from bed, and into an adjoining room if required, heavy and unwieldy patients, reduced to a state of helplessness by disease or accident

It is made of wrought iron, and the lifting power is obtained by means of a crane, which is raised or depressed by a screw. The crane is attached to a frame or carriage upon four castors, between two of which it is erected, and projects permanently over the carriage. From the end of the crane is suspended a cradle, by means of a swivel hook, which admits both of rotary motion and of being detached from the crane. The apparatus is moved or drawn by a handle attached to one of the front castors, and these being connected by a rod, attached to a small lever projecting behind each castor, they are brought into parallel action when moved, and the facility of turning greatly increased.

A narrow strong sheet with a broad hem along each side being slipped under the patient, and his pillows adjusted within the upper end of the sheet, a strong wooden rod is passed through each hem, and a leather strap being passed through a hem at the head of the sheet, is buttoned to the ends of the rods. Thus arranged and with such bed-clothes over the patient as may be required, the carriage is run under the bed, with the point of the crane brought over the patient in a line nearly corresponding with the umbilicus. The cradle is then attached to the crane and lowered so as to admit of the rods and sheet being hooked to each side of the cradle.

The patient is then raised from bed by turning the handle of the screw, and when sufficiently elevated may be drawn from it, either in the position in which he is raised, at right angles with the crane, or turned round into any other, more suited to the capacity of the apartment, or to his removal through doors and passages into an adjoining room. The length of the carriage is thirty-nine inches, and the width between the castors twenty-seven inches. It turns in a space seven feet square, is applicable to any size or shape of bed, and one person with a little practice is quite capable of working it,—of raising a patient of any dimensions from bed, and of moving him into an adjoining apartment.

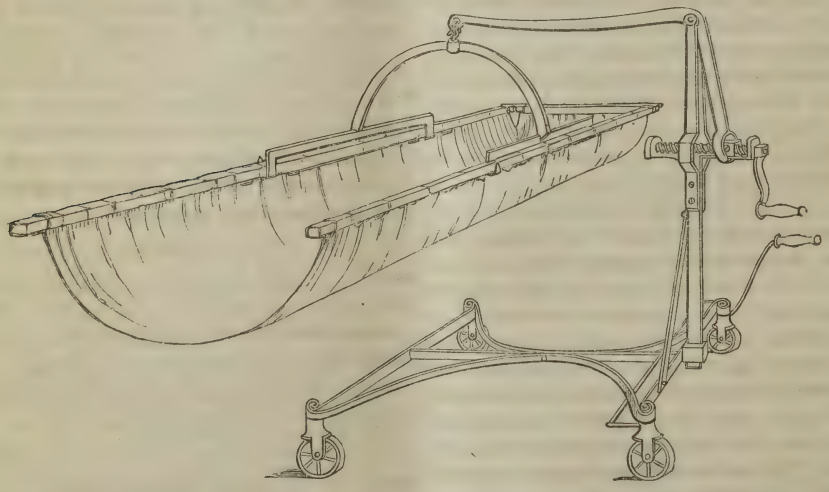
By means of a slit in the sheet, the patient can be readily placed upon a bed pan, and by joints in the wooden rods the legs are let down and he can be placed upon a night chair.

It also may be made available, occasionally, for the relief of patients disabled and confined to bed, but who retain the use of their hands and arms, viz., by attaching a stirrup-shaped handle to the crane instead of the cradle, and adjusting it over the patient in the position most favourable for him to lay hold of it, and thus enable him from time to time to alter and ease his position in bed.

The motion in raising a patient is so smooth and equal, that he can hardly perceive the precise moment at which he his elevated from his bed, and the efficiency of the apparatus altogether for the purposes intended has been satisfactorily tested by the result of several years' experience of its use. The price of each invalid lifter, with one pair of sheets, is £5. 10s.

This admits of a certain amount of profit which is to be devoted to the funds of the Stratford-upon-Avon Infirmary, and, as no personal pecuniary advantage is aimed at, from the sale of the apparatus, and as, in order to keep down the price, it has neither been registered nor patented, it is hoped that the medical profession and the public generally will protect the proposed benefit to the charity by ordering the apparatus through Dr. Thomson, or from Mr. James Ward, Wood Street, Stratford-upon-Avon, whose valuable assistance in the construction of it is here acknowledged, and who is the only person at present authorised to make and sell it.

Stratford-upon-Avon, August, 1851.



Hospital Reports.

BIRMINGHAM GENERAL HOSPITAL.

CASE ADMITTED UNDER THE CARE OF J. HODGSON, ESQ.,

(Reported by ALEX. H. PATERSON, Esq., Altringham)

Arsenical Poisoning.

Lucy H., married, aged 30. A fine healthy woman. Admitted at one o'clock, P.M., on May 26th, 1845. Her husband stated that nearly an hour before she had swallowed nearly a pennyworth of arsenic. She was in a profuse perspiration, her extremities cold, and her pulse small and quick. The stomach pump was at once used, and a quantity of clear fluid and white curdy matter removed. This, on being tested, was not found to contain arsenic. The stomach was well washed out with warm water, and a quantity of hydrated peroxyde of iron administered. She walked up stairs to bed. During the evening she vomited several times, and was thirsty. Her pulse rose, but did not increase in quickness.

10 P.M.—Pulse full. No pain in abdomen or at the pit of the stomach, except under severe pressure.

May 27th.—Has vomited and been purged several times during the night, and suffered from great thirst.

9 A.M.—Looked pale and exhausted; complained of slight pain in the lower part of the abdomen, but she had no pain in any other part of the abdomen or stomach, even when very firmly compressed. At half-past nine she left the hospital, at the desire of her friends. The pain in the bowels rapidly increased, was accompanied with vomiting and purging, and continued till her death, at half-past one, P.M.

Post-mortem examination, twenty hours after death.—The body looked pallid; the features were composed; the heart large, and both ventricles filled with black half-coagulated blood. On washing it the carneæ columnæ of both ventricles presented an ecchymosed appearance. Lungs healthy, much gorged with black blood. The stomach, on its lower external and anterior surface, presented a few thin ecchymosed spots, about the size of a split pea each. The great omentum and peritoneal surface of the intestines were of a light pink colour. On opening the stomach it looked dark, and its mucous lining was softened and thickened; on two places, about the size of a sixpence, near the greater curvature, it was abraded. The head of the duodenum was very dark, and its mucous folds extensively ecchymosed. It and the stomach were distended with a fluid of a light brown colour. The rest of the intestinal canal was normal in appearance, except a patch of redness and ecchymosis near the head of the cœcum, and a number of white spots, each the size of a pin's head, in the folds of the mucous membrane of the ilium, the surrounding intestine being very vascular. The uterus and brain were much congested, but otherwise healthy. The white specks in the ilium proved to be arsenic.

Remarks.—Professor Taylor, in his work on "Medical Jurisprudence," mentions that the action of arsenic is uncertain, and sometimes long delayed. In the case I have given I afterwards ascertained that probably half an ounce of white arsenic had been mixed in a cup of tea, and swallowed. She had doubtless been sick before she reached the hospital, some druggist having, I believe, given her an emetic, and no poison was left floating in the stomach, or removed from it by the pump. The *post-mortem* appearances, however, show how much reached the intestines. Still, from noon on May 26th to half-past nine on the morning of the 27th the symptoms were not more serious than might be easily accounted for by the use of the stomach pump and the antidotes administered. Acute inflammation of the contents of the abdomen must at the same time have been going on; yet severe pressure failed to cause pain or detect tenderness, except in a slight degree in one of the iliac regions. I regret that the imperfection of my notes does not allow me to give the exact state of her pulse; but I know that shortly before she left the hospital it was not *very* feeble, that she was perfectly sensible, and that she asked for and partook of some gruel with apparent relish. Her relations took her home contrary to the wishes of the house-surgeon, refusing to believe that she had really taken poison. I need not dilate on the importance of such cases, as from not being aware of their occurrence a surgeon may throw away the patient's chance of life, and injure his own reputation, by giving an opinion that no poison has been taken.

Altringham, July 14, 1851.

Provincial Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 3, 1851.

It is highly gratifying to those who take an interest in the progress of our Association, to find that the recent demonstration against quackery at the Anniversary Meeting has been so generally approved of; it shows that the profession itself is sound to the core, for though there may be, and evidently are, some rotten and defective portions, still the body has vitality enough to lop off the infected members, and we hope and trust to heal the wound necessarily caused by the act of severance. In the present crowded state of the profession there is, no doubt, great temptation held out to leave the beaten path, when the pursuing it in a straightforward and honourable manner has not produced the pecuniary results which every man has a right to expect. But while we pity we must still condemn, and fortunately for society at large, the profession themselves, who are best qualified to form an opinion on the subject, are also entirely unprejudiced, and have no personal interests to serve, for homœopathy is at least as easily practised, and is, most probably, more lucrative, than the prosecution of the doctrines of Hippocrates and his successors. If, therefore, it can be shown, as it easily can, that the profession, as a body, have no reason to oppose homœopathy, except from the knowledge of its utter inutility, there is a strong argument with the public against the delusion which is practised upon them; and this appears to be the only argument they are capable of appreciating. It is quite clear that the possession of the highest intellect does not guard a man against the belief in many impositions, unless the mind of the individual has been educated so as to take in and understand all the bearings of the subject. Thus the possession of the highest university honour does

not guard a senior wrangler against the arts of a nefarious horse-dealer, who may, perhaps, take him in with perfect ease, though unable to pass a "*screw*" off upon an illiterate country bumpkin.

There is no doubt that "a little learning is a dangerous thing," and in nothing is this truth more strongly shown than in the belief which has grown with the present generation, that all have some little knowledge of medicine. We fear this has been fostered by the popular lectures on subjects connected with medicine, which have been so generally delivered, and which have frequently been made so pleasant, and apparently so plain and simple, that ignorant people have gone away with the impression that they have acquired, in a few hours, more than is really obtained by the study of a life. And this, again, has led to apparent differences between medical practitioners, for two opinions may, and to our own knowledge have, often been given on a patient's case, perfectly similar in reality, but in the mind of an incompetent auditor, leading to entirely opposite conclusions, by which the credit of the whole profession has been materially affected. In arguing, therefore, with an unprofessional person, it is useless to combat homœopathy, mesmerism, or any other popular delusion, with the same arguments which we should use if engaged with one of our own body, who had lapsed, or was about to lapse, from the truth. We may often think that we have used unanswerable arguments with such a person, whilst all the while our seed has fallen upon barren ground, and has produced nothing but perhaps the obstinacy of ignorance. We think, therefore, that it will conduce to the interest, as it will certainly comport with the dignity, of the profession, to take our stand as we have done, by purging our own body, but carefully avoiding all discussion with such men as the Rector of Wickwar, alluded to by Dr. Cormack in his eloquent address at Brighton.

Let us only make it clear to the public that *we* have no interest in the matter, except, as we all have, to arrive at the truth, and to do this we have only to show the following propositions:— 1st, that the homœopathists themselves maintain, that when the disease is ascertained the treatment is easy enough; 2nd, that all parties, whether homœopathists or allopathists, can only use the same means to arrive at the knowledge of disease; and, 3rd, that the well-educated medical practitioner can, therefore, have no *difficulty* in practising homœopathy, his only objection to it being its utter want of truth, and by consequence its deficiency of power to combat disease.

We are well aware that fashion is all-powerful with some, and we do not expect to overcome it speedily, though we are confident in the final power of the truth. We think, therefore, that little good will be attained by any efforts, however praiseworthy the intention may be, to coerce public opinion, but that the course which the profession have to take is simply, as we have before stated, to maintain their own purity and dignity, and await with patience the time when the public mind shall be awakened to a sense of the folly and presumption of which so many otherwise clever and well-educated men have been guilty.

It must be evident to the profession that our Association has taken high ground. The President of the Royal College of Physicians attended the recent meeting of the Association, at Brighton, for the purpose of expressing, in the name of his College, the satisfaction felt by that body at the assembling together of so much talent as is united in this Association. "It is for you," said Dr. Paris, "and for you only, to determine what shall be the future state of the medical profession."

The importance of the Provincial Association consists of several elements capable of indefinite expansion. Apart from the high professional attainments which distinguish many of its members, and the combined zeal with which it has conducted its medical inquiries and researches, the Association, partaking of the spirit of its noble-minded founder, possesses a moral dignity which (without disparagement) may be said to grace no other purely medical body. It is pre-eminent in its *honesty* and its *charity*.

Its *honesty* was triumphant at Brighton. The most subtle forms of quackery may not be allowed to pollute any of its members. The resolution which will prove the death blow of homœopathy was passed *unanimously*. Every medical body must assume this tone, or it must perish; no half-measures will suffice. The enemy already quails before our united advance; but, in the prospect of an easy victory, we have not forgotten the sick and wounded in our ranks.

The *charity* of our Association is her glory. The Medical Benevolent Fund was the child of

her youth, it is now the cherished one of her maturer years, and it will be her solace when the wrinkles of age shall have settled on her brow. But other Institutions of a similar character are already growing up around her. The benevolent scheme of Mr. PROPERT, to which we are now anxious to call special attention, will probably find its best supporters among those whom the "fund" has taught the luxury of giving.

The Medical Benevolent College, though projected in London, is intended for the benefit of the provinces as well as of the metropolis, and, therefore, seeks the support of the Provincial Association as a necessary element of success. At the recent meeting, at Brighton, its honoured founder appeared for the purpose of pleading its cause; but he being unfortunately called back to London before an opportunity was offered for him to address the meeting, we were deprived of the privilege of hearing, from his own lips, the claims of the Institution on our attention. And it is to be feared that the eloquent harangue of Mr. LORD, at the close of the meeting, fell but too feebly on the wearied ear of the few members who remained at that advanced hour. But these circumstances do not at all affect our responsibility.

Our charity has begun at home; it is now invited to take a wider range. For many years the Medical Benevolent Fund held its Committee meetings in the country; it now holds them in London. The claims upon it are multiplied and increasing, and it must not be impoverished. But the College is equally necessary, and its claims are equally imperative. Both Institutions are intended for the benefit of the needy members of the profession in all parts of the world. Every branch of the Association should, at its annual meetings, follow the example of the Shropshire Branch at its recent annual meeting. The Medical Benevolent Fund should give rise to many "a long and animated debate." To that fund the members of the Association will probably subscribe before they contribute to Mr. PROPERT'S important scheme. And we would have them to do so, for this, among other reasons, that they will then become awake to the claims of both Institutions. He who has a real sympathy for the *actual* distresses of his brethren will not willingly miss the opportunity of *preventing* that distress. The *school*, by affording cheap and liberal education to our sons, will help us when we most need help. The *asylum* offers a home to those who might otherwise become a burden on the Benevolent Fund. The objects of both Institutions are, therefore, so similar, that we may live to see the day when the sister Societies shall be united in one common fund. But, at present, we are anxious that the claims of both should be clearly understood.

The sum required for the completion of the Medical Benevolent College, in addition to what is already subscribed, is no less than £18,000. It has been suggested that this sum might be raised by each member of the profession in England subscribing the sum of one guinea. But this may be doubted. And it is morally certain that many of our brethren cannot, and that others will not, afford a guinea for such a purpose. Still the sum must be raised: and it may easily be raised by the Association. Let each member, in the first place, subscribe his guinea, or five guineas to the Benevolent Fund; then let each determine that he will, during the month of September, collect from benevolent persons in his neighbourhood a sum not less than five or ten pounds. Let this be forwarded to Mr. PROPERT, or the Bankers to the College, Messrs. GOSLINGS and Co., 19, Fleet Street, before the first of January next; and by the end of that month we shall have to announce that the first stone is laid of one of the noblest Institutions ever founded by the medical profession. Let it be considered that the expense of collecting £18,000 in the usual mode would be great, and the time consumed very considerable. Mr. PROPERT has already collected, single-handed, upwards of £2,000. Mr. PROPERT is engaged very extensively as a general practitioner. He is one of those men whose time and strength are taxed to the utmost. Yet, see what he has done! Is there a member of the Association who will say that he *cannot* collect £10 for such a purpose? In fact there is no doubt that by proper exertion the sum may be easily raised.

We have met with two or three objections to these charities. Some men do not like the word "charity." Some fear that the scheme will encourage idleness or improvidence; others object to the school because a chapel is to be attached; others approve of the school, but dislike the idea of alms-houses, as degrading to the profession.

There is but one reply to these and similar objections. Charity, and alms-giving, and public worship, are all of divine appointment, and have been practised at all times, by all good men, in all nations.

It would be well for the profession if there were fewer of its members in distress. But which is the most degrading of the two positions,—distress alleviated by charity, or distress unalleviated? Is it less disgraceful to see a member of the College of Surgeons begging in the streets than to see him comfortably lodged in an alms-house? Is it more creditable to the profession to see a physician pauperized—actually habited in the "union" costume, than to see him attired as becomes a gentleman, and partaking of his frugal yet sufficient meal in a convenient cottage, surrounded by the society of his equals? The distress and penury of very many respectable members of the profession—nay, of some who, by their discoveries, and researches have been the benefactors of mankind, is a *fact;* an unseemly degrading fact, if you will, but a *fact.* And none of us can tell how soon it may be our lot to suffer under the miseries of disease and want. A graduate in medicine, who once possessed a fortune of thirty thousand pounds and a practice of three thousand a year—a man of excellent character and gentlemanly habits—is now, from the combined influence of disease, misfortune, and advanced age, reduced to absolute want, having been rescued from starvation by a medical charity. And to such sufferers, who, in the days of their prosperity, may possibly have seen in the proposed College, but an undignified confession of professional poverty, Mr. Propert's asylum will offer a welcome refuge, even though they have written volumes against the *principle* of the Institution.

It will be in the recollection of our readers that a review of Dr. Tunstall's book "On the Bath Waters," which appeared in this journal some months ago, gave offence to some members of the Association; this we much regretted at the time, although we did not very clearly see the occasion of it. We received the manuscript of that review from Bath, accompanied by a private note, to the best of our memory, signed, "W. Davies." We entertained no doubt of the article having been written by Dr. Davies, of that city, and as we thought him a competent authority on the subject, we were very glad to insert the review. Subsequent inquiries were made of us as to the name of the author, and as we were not aware of any reason for secrecy, we stated, according to our own belief, that it was written by Dr. Davies. It appears, however, that it was not written by that gentleman, and that he had no knowledge of the article, nor by whom it was written. It is obvious, therefore, either that the signature attached to the note in question was a forgery, or that there is some other person of the same name in Bath by whom it was written. If the former supposition be the true one, it is a disgraceful affair, and one against which no amount of Editorial caution can avail.

We have given the above explanation in justice to Dr. Davies, and not from any desire to shift the responsibility from ourselves, as, of course, we are responsible for whatever reviews are published in this journal.

Proceedings of Societies.

MEDICAL BENEVOLENT FUND.

SIXTEENTH ANNUAL REPORT OF THE MEDICAL BENEVOLENT FUND FOR THE YEAR 1850-51.

Read at the Nineteenth Anniversary Meeting, held at Brighton August 13, 1851.

Another year has passed away; and in again addressing their subscribers, your Committee have cause to congratulate you upon your progress towards maturity, and upon the development of your resources.

Notwithstanding the many unfavourable circumstances which have operated against your enlarged efforts, your Committee have to notice as chief causes of thankfulness, first, the success of their plan in altering their place of meeting to London; next, the harmony and efficiency with which their deliberations have been conducted; thirdly, the amount of misery they have been enabled to relieve; and, fourthly, the enlargement of their income.

Notwithstanding the severe pressure upon professional resources, arising from agricultural distress, and the loss of many of their subscribers from death, or changed private circumstances, your Committee rejoice to announce that their income for the year ending June 30, has been £540. 1s. 4d., exceeding that of last year by nearly £50.

The amount of donations has been lessened; this however was to be expected, as the preceding year had been one of special appeal; yet £188. 15s. 6d. have been received, and the amount invested in bank stock

has been £214. 14s. 6d., thus making your permanent fund £1,200 in bank stock, which at the present price of that stock only produce £2,568.

Your Committee would further congratulate you on the commencement of their annuity scheme. Four annuities have been granted during the last year, and two half-years have been paid, amounting to £75. The extension of this part of their plan must depend upon the zeal with which they are supported; but they hope to be enabled, by your liberality, to enlarge this mode of relief from your fixed or permanent income.

One of the circumstances which has operated against the prosperity of your Institution, has been the activity and zeal with which the British Medical Fund has been advocated, and pressed upon professional attention by the exertions of its valuable Secretary.

Yet your Committee, so far from undervaluing the British Medical Fund, do consider it as an instrument of great usefulness. When it is recollected, that medical men are generally poor, that they marry early upon insufficient incomes, and that the value of their lives is very much below the average value of life in the other professions, *cæteris paribus*, it will follow as a matter of duty, that each individual should lay by him in store, for the event of sickness,—for the contingencies of after life, and for the certainty of death,—that upon the occurrence of this last event, his family may not be dependent upon charitable relief. To such thoughtful individuals, the British Medical Fund offers greater advantages than can be afforded by any ordinary insurance society, and it is restricted to members of the medical profession.

Facts, however, have shown, and have especially shown in the last year, that no providence in the earlier part of life—no primary success—no splendid standing in the profession—no large income—can secure either themselves, or their decendants from the reverses of calamity or from the dire approach of want. Facts have proved, as will be shown by a reference to the list of cases relieved, that no early prosperity can exempt a man or his family from the probability of future distress, and while these facts should warn us of the importance of making provision for the future, and should inculcate upon every one a lesson of humanity and prudence, they should still more deeply awaken the noble and christian sentiment of sympathy and active benevolence towards our brethren in their hour of need; "Let those who have much, give of their abundance; let those who have little, give gladly of that little, and assuredly they shall not lose their reward."

If there be one circumstance more conclusive than another, during the history of the last year, it is this, that the existence of a purely charitable fund is indispensable for the relief of a great mass of professional misery, which is *unrelieved*, and *unrelievable* by all the provident institutions combined; and, therefore, the necessity for the existence of the "Medical Benevolent Fund" becomes every day more and more apparent.

While, then, your Committee would earnestly entreat practitioners everywhere to insure their own lives, as a duty which they owe to their families, to the profession, and to society at large; they would also point out the advantages of your own fund, as offering a measure of relief to those who have been unable to effect or to continue this provision, and they invite your especial attention to the *simplicity of its object* and the *efficiency of its working*.

Its object is simple—the immediate offspring of that christian charity which forms the chief ornament of the character; it originates in the heart, and it seeks its way to the heart of the distressed. A reference to the cases appended to this report will show that it requires not any special qualification, but extends its immediate aid to distress, provided that such has not been the consequence of immoral habits.

But it is also efficient in its working; relief has been afforded during the last year to forty-six applicants, at a cost of £464. 2s. 6d., besides the sum of £75 paid to annuitants, making a total of benevolent aid during the year of £539. 2s. 6d. The relief thus given has not only been efficient, but it has also been discriminating; the cases have been minutely investigated, and those only have been relieved which could bear this minute investigation, and could be proof against this searching ordeal.

But your Committee acknowledge that their relief has been inadequate; they have been obliged to vote £5 or £10, where their judgment and conscience have told them a much larger sum was required: and they have done violence to their own feelings because they had no more *in* their hands, and this brings them to the humiliating acknowledgment that your fund has not been supported by the profession according to its merits; those who are above the risk of needing benevolent aid, have probably thought that others were like themselves, or have been contented with *private charity*, forgetting that a society like yours was the very one to *investigate* cases, and to prevent that imposition to which each one in his private capacity must be subjected. While the coldness of the prosperous is probably thus to be accounted for, the apathy of the great mass of the profession is only to be explained on the plea of wilful self-deception, believing that misery does not exist, because they do not see it.

Your Committee, therefore, entreat all to look to the list of cases relieved; and they appeal to you in favour of the Benevolent Fund by the simplicity of its object, —by the efficiency and discrimination of its working,— and by its high principles and motives, and claims to universal support; or they earnestly entreat each one of their subscribers to obtain *several other contributors* from the immediate circle of their personal friends, and so to present a phalanx of adherents, which shall prove itself invincible in action, as well as unequalled in value.

During the past year, a benevolent lady has had your report reprinted at her own cost, for distribution among her friends. This example of generous devotion to your cause is deserving of imitation, and is only equalled by that undying attachment to your fund which has also been evinced by others of your kind lady friends; to them, individually, and to all others similarly engaged, your Committee beg to offer their especial thanks.

Your Committee have to regret that the working of your Society has been rendered difficult by the want of the early payment of subscriptions, and must have been several times suspended but for the good-humoured advances of their Treasurer; they, therefore, entreat attention to this want "*bis dat qui cito dat.*"

Your Committee beg to express their sympathy to their President, Dr. Baron, whose continued ill-health has prevented his presiding at their meetings, and whilst they have had repeated testimonies of his care for your Society, they request his constant remembrance, and beg to offer their best wishes for his restoration.

To their non-professional donors and subscribers, and particularly to their valued friend and banker, Sir Walter Farquhar, Bart., they beg to tender their best thanks.

To the medical press generally the Committee offer their acknowledgments, and especially to the *Medical Gazette*, for whose *amende honorable*, and ample notice of their proceedings, they are especially obliged.

Your Committee having arrived at the conviction that they required some other means of making their proceedings more widely known, and of exciting a greater interest on their behalf, after much deliberation have resolved in holding a public dinner on your behalf during the next spring; and they beg the kind considerations of their friends to this notice.

In conclusion, your Committee would review the history of the past, and their present position; and to each one of their subscribers, as well as to each member of the profession, they would say,—be just to thyself, and insure against all the emergencies of life; but be charitable to thy brother—"be merciful after thy power," and contribute through the *one only channel* of pure charity—the Benevolent Fund—to the relief of distress, which they pray God *you* may never feel; but should such be your lot in this day of trial, and in this changing world, they equally pray God you may never want the aid of the Benevolent Fund without obtaining it,—a result which can only be insured by its being adequately supported.

Signed on behalf of the Committee,

WILLIAM NEWNHAM,
Chairman.

EPIDEMIOLOGICAL SOCIETY.

The last meeting of the first session of this Society, was held at the house of the Royal Medical and Chirurgical Society, 53, Berners Street, on Monday the 4th of August.

DR. BABINGTON IN THE CHAIR.

After the usual routine of business, the President announced that the Report of the Common Lodging Houses' Committee had been presented to the Council, and received by them, to be made such use of as shall seem best to the President and members of that Committee. During the meeting the President stated, that although there would be no more ordinary meetings held till November, yet the various Committees would remain in active operation, and invited communications from members and others on the subject of epidemics in general, especially that of small-pox and vaccination, to be forwarded to the Honorary Secretaries, 38, Berners Street, Oxford Street.

The paper announced to be read at the first meeting of the Society in November, is "On Epidemic Diseases in Ireland," by Dr. Robert Gordan Latham.

At the usual period of the meeting, Dr. Mc William, one of the Honorary Secretaries of the Society, was called upon by the President to read Mr. Grove's paper "On the Nature of Epidemics."

Mr. Grove commenced his paper by quoting a saying of the Rev. Sidney Smith, that "words are an amazing barrier to the reception of truth;" which he applied to miasmata, mephitic vapours, morbid poisons and their synonyms, remarking that they were words in common use, but that they conveyed no definite meaning to the mind. He then said that the object of his communication was to elucidate that view which held that the poisons inducing epidemic, endemic, and infectious diseases must be ranked among the things endowed with life. He argued that the faculty of reproduction was a distinctive mark between animation and mechanism, or between living and inanimate matter. That it was during the reproductive period of existence that the most energetic operations of the vital force were manifested, and that it was during the reproduction of the poison germs within the body, that the force of diseased action called for our special attention. He called attention to the fact that, whether we examine an epidemic or infectious disease of plants, animals, or of man, we find that the essence of the affection is a something which has the power of reproducing its species. Taking, then, this faculty of reproduction as indicative of the existence of a germ, the author classed the agents of disease among living things, and regarded reproduction as the primary law. He then argued, that if this were a correct interpretation of nature, the germs of disease ought to acknowledge obedience to the same subsidiary laws which regulate or influence animate existences. He divided these laws into the objective and subjective; the former referring to faculties or properties inherent in the germ; the latter referring to the action of external agents and influences upon them. The laws named, ten in number, are not intended as absolutely definite expressions of a comprehensive idea, but merely as the readiest approximations.

Objective Laws.	*Subjective Laws.*
1. The diffusion or dispersion of germs.	1. Seasons of activity.
2. Their static existence.	2. Climatic influence.
3. Duration of active existence.	3. Relation to latitude.
4. Period of development.	4. Subjection to physical forces.
5. Intermittent reproduction.	5. Influence of locality.

The application of these laws to the agents of disease, was demonstrated, and their analogies traced in the vegetable and animal kingdom. He further showed that upon this mode of explaining the phenomena of infectious diseases, little else was required to solve some of the most difficult problems connected with them. Having shown the impossibility of accounting for epidemics and infection upon the chemical basis, seeing that in no purely chemical process was there any multiplication of the agents, and that as far as the physical

forces were concerned, one always increased at the expense of the other, as heat increases by the chemical change taking place in combustible bodies; the author concluded by drawing attention to the Registrar General's Return of Deaths for the year 1847, by which it might be seen that, as 97,924 deaths were due to epidemic, endemic, and infectious diseases, nearly one-fourth of the total mortality was attributable to causes especially demanding the attention of this Society; and if we were allowed to include consumption, considerably more than one-third; the numbers being of the diseases mentioned 151,241, and the total mortality for the year, 453,723.

An animated discussion followed the reading of Mr. Grove's paper, in which Dr. Babington, Dr. Silvester, Dr. Snow, Mr. Charles Cochrane, and Dr. Mc William, took part.

A vote of thanks was awarded to Mr. Grove, in his absence from the meeting, for his interesting paper.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

THE debates at this Academy during the past month have been comparatively uninteresting, the following communications only being worthy of record:—

M. ROBERT reported on a case of enormous *hypertrophy of the mammæ*, in which extirpation of both breasts was performed. The enlargement commenced at the age of 18, as a consequence of suppression of the menses. The shape was pyriform; the colour a deep purplish red, interspersed with numerous blue lines, indicating the course of enlarged veins. They were soft externally, but deep pressure discovered a number of hard nodules, the size of filberts. In 1842 one was punctured, but a little blood only escaped. In 1844, three years after the commencement of the affection, both breasts had acquired such enormous dimensions as to reach the knees while the patient stood upright. The weight was so great as to cause her to keep the recumbent posture. The operation was performed without danger; the breast being strongly compressed at its base between two strong pieces of whalebone, for the purpose of preventing excessive hæmorrhage. As soon as one wound had healed the other breast was excised. On examination, the tumours were found to be composed of fatty tissue, containing indurated nodules. One weighed thirty pounds, the other twenty. After their removal the patient greatly improved in health, and recovered her enbonpoint.

M. DEVILLIERS, jun., read a memoir "On the *Normal Dimensions of the Female Pelvis*." The chief conclusions to which he has arrived are stated to be as follows:—1. The sacro-pubic diameter may be as low as three inches and a half, without the least appearance of malformation or disease of the bones. 2. The coccygo-pubic diameter in three-fourths of the cases examined by him has been less than four inches. 3. The bisiliac diameter of the upper outlet is subject to little variety, the mean being five inches. 4. The bisischiadic diameter, on the contrary, is frequently under the average. 5. In nearly half the cases examined the left oblique diameter of the brim is greater than the same diameter of the opposite side. 6. It is rare to find an instance of a pelvis offering all its diameters of the mean lengths. 7. The diameters of the fœtal cranium, as they are presented in the different stages of labour, are less than the corresponding diameters of the pelvis. 8. The principal diameters of the pelvis may be considerably below the average without offering serious impediments to parturition.

ACADEMIE DES SCIENCES.

M. JOBERT (de Lamballe) read "An Essay on *Foreign Bodies in the Air Passages*." He does not, however, in any degree extend our knowledge on the subject. The same may be said of a communication by M. DUHAMEL "On *Compression of the Aorta in Uterine Hæmorrhages*."

SURGICAL SOCIETY OF PARIS.

THE *Treatment of Erectile Tumours by Vaccination* has been successfully carried out by M. Marjolin, in an instance recently related to this Society. The diseased congeries of vessels occupied the temple, both eyelids, the cheek, and the lips, as well as the mucous membrane of the lips and palate. It was decided, on consultation, that nothing could be devised to remedy so extensive a disease; but as the patient, a little girl, had not been vaccinated, M. Marjolin made fifteen or sixteen punctures around the morbid tissue, and inserted vaccine matter. Great inflammation ensued and spread over the whole tumour. At the end of three years it was found that a most unhoped for amelioration had taken place. The characters of erectile tissue had almost entirely disappeared, and in its place a firm whitish integument was seen, which was more deficient in vascularity than natural skin. Several members offered remarks on this fortunate case. In the opinion of the majority vaccination generally fails, even in tumours of small size.

The *Treatment of Abscesses by Injection* was brought before the Society by MM. CHAISSAIGNAC and BONNET. The former mentioned his proceeding, which consists of first evacuating the matter, and then repeatedly injecting the abscess with cold water until it comes out untinged. The sac is then brought into apposition by bandages.

M. Bonnet confirms the advantages of injecting strumous abscesses with tincture of iodine, either pure or diluted; at the same time he gives iron and cod-liver oil internally, and allows a liberal diet.

Nux Vomica in Asthenic Dropsies.

M. Tessier (*Revue Medico-Chirurgicale*, June, 1851) states that the preparations of nux vomica may be

advantageously used in asthenic dropsies complicated with generally debilitated health, as after chronic diseases, or in consequence of insufficient food. He explains the action of this drug on the supposition that by favouring an active state of digestion and defecation, it prevents abdominal plethora, and encourages rapid venous absorption.

On the Pathology and Treatment of Varicocele.

In a thesis with this title, M. Prunaire (*Gazette Medical de Strasbourg*) speaks of a new mode of treating varicocele by caustic. He also enters minutely into certain anatomical considerations calculated to throw light on the pathology of the disease. In the first place he has taken the measurements of the right and left spermatic veins in fourteen cases, together with the comparative weight of the testicles on either side. In classing the subjects according to their ages, he finds that between the ages of 3 months and 2 years, there was a difference of from one to two centimetres in favour of the left spermatic vein; between the ages of 30 and 35 years the difference was from two to three centimetres. As regards the size of the testicles, the author has constantly found the left larger and heavier than the right.

A recent writer has given the absence of valves in the spermatic veins as the cause of varicocele, but this the author refuses to admit, as he concludes from the observations of St. Helaire, as well as from his own researches, that valves are present in these veins in the majority of instances; this of course suffices to vitiate the theory arising out of their presumed absence.

The treatment adopted by M. Prunaire is thus described:—The pubes being denuded of hair, the patient is requested to walk for an hour or two; he is then chloroformed. An incision is next made over the cord, the sheath is opened with the utmost caution, and the veins scrupulously isolated from the other structures; this being done, some lint is passed underneath them to prevent the contact of the caustic with the subsequent tissues, and the veins are daubed with Vienna paste. After a few minutes the caustic is sedulously removed by washing the part in a dilute acid solution, and the wound is dressed. The veins which have been touched shrivel up, and when the eschar falls, are found to be completely obstructed.

Death of Dr. Baudelocque.

This distinguished physician has lately sunk under a chronic malady, aged 55. He is well known to English readers as a writer on obstetrical subjects, and on scrofula. He was physician to the Hospital for Sick Children, and had one of the largest midwifery practices in Paris

The *sweating sickness* has broken out in several localities in the department of Herault.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Pathology of some Affections of the Ear which induce Cerebral Disease.—By Mr. Toynbee.

Mr. Toynbee has presented a memoir to the Royal Medico-Chirurgical Society, in which he has endeavoured to specify the diseases of the ear which are liable to extend to the brain, as well as to shew that each division of the internal aural apparatus has its particular division of the encephalon to which it communicates disease. He states, for instance, that—1. Affections of the external meatus and mastoid cells produce disease in the lateral sinus and cerebellum. 2. Affections of the tympanic cavity produce disease in the cerebrum. 3. Affections of the vestibule and cochlea produce disease in the medulla oblongata. In speaking of the external meatus, its intimate relations with the lateral sinus and cerebellum are pointed out; the affection most frequently producing disease in these parts is shown to be catarrhal inflammation of its dermoid layer, one of the numerous diseases which have hitherto been classed together under the term otorrhœa. This affection of the external meatus is fully described; and it is shown that it is found to endure during many years, without the presence of pain, or any other symptom calculated to apprise the surgeon of the presence of a formidable disease, while the bone may be becoming slowly carious, and portions of the dura mater and cerebellum disorganized. In the second division of the paper, the tympanic cavity is described to be the part of the ear from which disease is most frequently propagated to the brain. This circumstance is accounted for, firstly, by the great liability of the mucous membrane of the tympanum to undergo pathological changes; and, secondly, by the existence of very intimate relations between this membrane and the dura mater. The affection of the tympanum which most frequently produces disease in the cerebrum is chronic catarrhal inflammation of the mucous membrane, an affection thus far only known as an otorrhœa. The four changes in the dura mater and cerebrum produced by the affections of the tympanum are—

1. Inflammation of the dura mater, and its separation from the surface of the petrous bone by serum.

2. Ulceration of the dura mater, and its complete detachment from the petrous bone.

3. An abscess in the substance of the cerebrum.

4. Undefined suppuration of the substance of the cerebrum.

From a careful examination of cases, it appears that chronic catarrhal inflammation of the mucous membrane of the tympanum may exist as many as twenty or more years, without the production of any disease beyond it, or at least, without the existence of symptoms by means of which the presence of such disease can be diagnosed; nevertheless, in the great majority of cases vital structures become sensibly affected in a

much shorter period. In a third section of the paper the author devotes some space to the consideration of the labyrinth, and it is shown that purulent matter in the vestibule or cochlea sometimes causes disease of the auditory nerve, which is transmitted to the medulla oblongata, producing suppurative inflammation of the meninges, and death, without the presence of any caries of the bone. In the course of this paper the author shows the necessity of abolishing the use of the term otorrhœa, and of using in its place the names of the several diseases, eight in number, of which a discharge from the ear is one of the symptoms. In conclusion, the facts which he is desirous of impressing upon the minds of medical men are, that the bone, dura mater, and substance of the brain may be slowly undergoing disorganization, without the presence of any other symptoms calculated to reveal to the medical man the existence of formidable disease than the presence of a discharge from the external auditory meatus; and that, consequently, no person suffering from catarrhal inflammation of the dermoid layer of the meatus, the membrana tympani, or of the mucous membrane of the tympanum, can be assured that disease is not being prolonged to the temporal bone, the brain, and its membranes; and that any ordinary exciting cause, as an attack of fever or influenza, a blow on the head, &c., may not induce the appearance of acute symptoms, which, as a general rule, are speedily fatal.—*Medical Times.*

PRACTICAL MEDICINE AND PATHOLOGY

On Cod-liver Oil in Phthisis.—By Dr. Walshe.

The following conclusions as to the value of the cod-liver oil are taken from the author's recent work on "Diseases of the Lungs." He states:—

1. That it more rapidly and effectually induces improvement in the general and local symptoms than any other known agent.

2. That its power of *curing* the disease is undetermined. I mean here by curing the disease, its power of causing, along with suspension of progress, such change in the organism generally as shall render the lungs less prone to subsequent outbreak of tubercles, than after suspension occuring under other agencies.

3. That the mean amount of permanency of the good effects of the oil is undetermined.

4. That it relatively produces more marked effects in the third than in the previous stages.

5. That it increases weight in favourable cases with singular speed, and out of all proportion with the actual quantity taken; that hence it must, in some unknown way, save waste, and render food more readily assimilable.

6. That it sometimes fails to increase weight.

7. That in the great majority of cases where it fails to increase weight, it does little good in other ways.

8. That it does not relieve dyspnœa out of proportion with other symptoms.

9. That the effects traceable to the oil in the most favourable cases are:—increase of weight, suspension of colliquative sweats, improved appetite, diminished cough and expectoration, cessation of sickness, with cough, and gradual disappearance of active physical signs.

10. That in some cases it cannot be taken, either because it disagrees with the stomach, impairing the appetite, (without itself obviously nourishing), and causing nausea, or because it produces diarrhœa.

11. That in the former cases it may be made palatable by association with mineral acid, and in the latter prevented from affecting the bowels by combination with astringents.

12. That intra-thoracic inflammations and hæmoptysis are contra-indications to its use, but only temporarily so. I have repeatedly given the oil within a day or two after cessation of hæmoptysis, without any return taking place.

13. Diarrhœa, if depending on chronic peritonitis, or secretive change, or small ulcerations in the ilium, is no contra-indication to the use of the oil; even the profuse diarrhœa caused by extensive ulceration of the large bowel is not made worse by it.

14. That the good effects of the oil are, *cæteris paribus*, directly as the youth of those using it—a singular fact, which probably may one day (when the textural peculiarities of youth and age are better understood,) aid in giving a clue to its mode of action.

SURGERY.

New Mode of Treating Epiphora.—By Mr. Bowman.

This plan consists in slitting up the canal from the punctum on the conjunctival aspect, so as to carry backwards the orifice at which the tears are received on to the mucous membrane near the caruncle; and Mr. Bowman finds that the tears are in fact taken up by the remaining portion of the canal, while the end towards the punctum is converted into a groove. For the cases of obstruction from injury or other cause he suggests a modification of this operation, by which the canal between the obstruction and the sac may be slit up for some way, so as to receive the tears at a new opening. The cases to which these new operations are applicable have been for the most part abandoned by surgeons as incurable.—*Medical Times.*

Dislocation of the Femur on the Pubes Reduced after eight weeks.

The patient, a powerful man, fell down epileptic, at the same time giving his leg a twist. When he recovered his senses he found swelling and pain of the left thigh. He was admitted into the Dorset County Hospital, when the following particulars were ascertained:—The leg was found to be two inches shorter than the other, and everted, the heel of the left foot being on a line, and at a right angle with the malleolus of the right; the head of the bone was distinctly felt resting on the pubes; the limb is free from pain when at rest; pain is however produced on attempting to invert the foot or flex the thigh on the pelvis. He could only progress

with the aid of crutches. A consultation was held, and it was agreed that an attempt should be made to reduce the limb. The patient (having previously been bled, and chloroform administered) was laid on the sound side, and the pulleys applied, extension being made in a direction backwards and downwards; this was kept up for more than an hour, frequent attempts being made in the meantime to lift the bone over the pubes and edge of the acetabulum by means of a towel placed round the upper part of the thigh, but without success. Paletta's plan of abducting the thigh, and then suddenly violently bending it towards the belly, was tried; also, that of bringing the patient to the edge of the table, and pushing the knee suddenly and forcibly backwards, at the same time adducting the limb as strongly as possible, but without apparent effect. The surgeon then requested an assistant to endeavour to lift the head of the bone with a towel placed round the upper part of the thigh, whilst he grasped the heel of the affected limb firmly with his left hand, and with the right hand placed on the outside of the knee, endeavoured to rotate the limb inwards. Under each attempt to rotate the leg some of the adhesions were heard to give way. In a short time the limb rotated inwards more freely; the pulleys were then slackened, and the thighs approximated when it was found that the limb lay nearly straight, the foot could be inverted, and the leg more easily moved in any direction; it appeared about an inch and a half shorter than the other. He was then put to bed, the legs being fastened together with a bandage, and fomentations applied to the hip.—*Lancet*, August 2.

MIDWIFERY AND DISEASES OF CHILDREN.

Treatment of Ophthalmia Neonatorum in the London Ophthalmic Hospital.

The treatment which is pursued at the Royal London Ophthalmic Hospital, in these cases, is simple and effectual; it consists, in general, of nothing more than the frequent injection over the front of the eyes and between the lids, of a solution of alum, (alum, gr. iv., water, oz. j.,) and then anointing the lids with lard, to prevent adhesion. If the inflammation is very severe and recent, the first syringing is with a solution of nitrate of silver, (gr. iv. to oz. j., never stronger,) and afterwards with the alum, the latter being thrown over the conjunctiva so as thoroughly to cleanse it, every half hour, every hour, or every two hours, according to the intensity of the inflammation, and the rapidity with which the purulent secretion is renewed. After each syringing, the lard is applied, so that the lids may not agglutinate in sleep. No leeches, blisters, or other auxiliary means are used; nor are the solid nitrate of silver, or strong ointments of it, ever employed. Leeches, though sanctioned by even so judicious an authority as Dr. Mackenzie, are deemed unnecessary; and they are certainly hazardous at this tender age, and in this situation, especially among the poor, treated as out-patients. And the astringent solution, of moderate strength, is considered at least equally efficacious with the solid caustic, while it gains more uniform access to all parts of the inflamed membrane, and it is a safer and less painful remedy.

The effect of this treatment is soon apparent, in a decided diminution in the discharge, and its more gleety nature, in lessened vascularity and intolerance in spasm, as well as in the altered temper of the infant. A few days are generally sufficient to produce these results, and the subsequent progress is steadily onwards to recovery. And the advantage of it is, that it is equally applicable in all periods of the inflammation characterised by purulent discharge. If used early it saves the eye, if delayed till the cornea has suppurated or ulcerated, or the iris or lens protruded, it has the salutary effect of arresting the disorder, and preventing further destruction; and a very great advantage indeed is this, one perhaps hardly predicable of any other remedy in any other disease, at least to the same extent. The simplicity of the treatment, and its general appropriateness to all forms and stages of the disease, should serve to give it currency among those little conversant with eye diseases, and may even sanction its use by the parish midwives as a nurse's remedy, of course only where the aid of a regularly educated medical man cannot well be had.—*London Journal of Medicine*, May, 1851.

On the Induction of Premature Labour.

At a late meeting of the Edinburgh Obstetrical Society, Dr. Moir made a statement of the mode of inducing premature labour, which was introduced by the late Dr. Hamilton. The plan consisted in gently dilating the os uteri with the finger or a catheter, and separating the membranes from the cervix without rupturing them. When labour came on it proceeded as in the natural way, and the probability of the life of the child being saved was much increased by avoiding a premature rupture of the membranes. When this proceeding failed to induce labour, Dr. Moir was in the habit of passing a catheter along the posterior surface of the uterus, between it and the membranes, and, by means of the stilet, puncturing the latter high up. By these means he had succeeded in every case but one.

Dr. Simpson is in the habit of inducing premature labour by dilating the os with sponge tents; and he considers this a more certain as well as a more safe mode than any other. Like Dr. Hamilton's plan, it had the advantage of not rupturing the membranes. It had also, in Dr. Simpson's opinion, other advantages. He has tried Dr. Kiwisch's plan of injecting a continuous stream of tepid water against the os uteri in one case with success.—*Edinburgh Monthly Journal*, July.

Rupture of the Uterus under peculiar circumstances.—By T. Berncastle, Esq.

The author was called to a woman in labour, who had engaged a midwife; this person had been sent for in the night, and after staying an hour or two went away. Between this time and eight in the morning, when the author saw her, labour had come on with

vigour, and a dead child was born in a few minutes; the placenta came away steadily. There was no hæmorrhage, and the uterus contracted well. Under these conditions he left her quiet, but cheerful. Two hours after he was summoned in great haste, as the woman was dying. He found her, to his surprise, speechless, cold, without pulse, in fact in *articulo mortis*. No hæmorrhage had occurred. She died in an hour.

Post-mortem examination.—Body that of a well-formed, stout woman. *Chest:* Heart and lungs perfectly healthy. *Abdomen:* Liver, kidneys, and other abdominal viscera, all healthy, but pale. The uterus was large, uncontracted, and rose above the umbilicus. On examining the appearances presented about the lower part of the uterus, a dark, extravasated appearance was observed on the right side, at the situation of the right lateral ligament. On removing the uterus, which was done by cutting through its neck, a great quantity of blood escaped, and a number of clots, amounting to about two pounds, were discovered. The internal surface of the uterus was now exposed, but excepting that it was not contracted in the usual manner after parturition, it did not present any abnormal appearance. There was no effusion of blood in the cavity of the uterus itself. The neck of the uterus was now particularly examined, and it was found to present a ragged and ulcerated appearance, and was covered with blood, partly coagulated and partly fluid. A great quantity of this blood lay immediately beneath the reflexion of the peritoneum, passing from the uterus to the bladder.

It appeared that there was an ulcerated condition of the uterus, which had probably existed for several years, and after the labour it is probable that the wall of the neck of the uterus gave way, causing an effusion of blood, not only into the neck of the uterus, but also into the cavity of the abdomen, *beneath the peritoneum;* and that this sudden effusion of blood was the cause of the woman's death.—*Lancet*, July 26.

Correspondence.

MR. BOTTOMLEY ON MEDICAL REFORM.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—Will you have the kindness to give insertion, in an early number of the *Journal*, to the following remarks in reference to what took place at the meeting of the Association at Brighton.

Dr. Cormack moved the adoption of the Report of the Council, seconded by Dr. F. Winslow, to which Dr. Crisp moved an amendment; in so doing he styled himself an old Medical Reformer, and a one-faculty man; he disapproved of the conjoint examining board of the College of Physicians and Surgeons, and ended by moving an amendment.

I felt desirous of replying to Dr. Crisp, but feared it might occupy much valuable time, and perhaps bring about a lengthened discussion, and prevent the reading of papers, &c., on subjects of greater importance; I therefore judged it more prudent not to interrupt the proceedings of the meeting, but to adopt the present plan.

That Dr. Crisp is an "old Medical Reformer," I am fully aware; he was one of the Council of the British Medical Reform Association, which was a very powerful and influential body, and one that was productive of much good; there were some of the leading professional gentlemen on the Council with Dr. Crisp, and I also had the honour to act with him. Our object then, was to form a faculty of medicine and surgery in this country, and I cannot give up the idea that such is the only means of placing the medical and surgical profession in its proper position.

Dr. Crisp is of the same opinion as myself, but we differ as to the method of bringing about so desirable an object. I feel quite sure that Dr. C.'s plan, viz., that of establishing another college, called a General Practitioner's College, with such very limited power as the National Institute appear to be satisfied with, will not in any way lead to such a result. If such a college be obtained, the profession would stand thus,—a College of Physicians, a College of Surgeons, and a College of General Practitioners, making the *three* grades, or classes, viz., Physicians, Surgeons, and General Practitioners. Once procure a bill for those *three* Institutions, and the *three* grades are perpetuated, and we shall be placed in a worse position than at present.

One of the suggestions, (viz., 13th), which I, (being one of a reform deputation), had the honour to submit to the College of Surgeons, December 19th, 1849, was—"That the examinations on the admission of fellows and members should be extended to the principles and practice of medicine, midwifery, and pharmacy. This would be a step towards the *one-faculty* system, *i.e.*, that of forming an examining board from the present Institutions. Such a principle, once admitted, and acted upon, the accomplishment of the *one*-faculty, in my opinion, would be easy. After having submitted to the Council of the College my suggestions, (which had been approved by the Council of the Institute), I stated to the former, that in case they should decline to act justly towards the members of the college, those members would feel themselves called upon to make a powerful effort to obtain *another* college; *(not,* however, a College of *General Practitioners,)* which is an absurd title, and one which would meet with every opposition from country surgeons), but "a Royal College of Medicine and Surgery, an Institution which should possess full power to confer on its members the right to practise medicine and surgery, in all their departments throughout the kingdom."

At that time, the Council of the College of Surgeons did not deem it advisable to listen to the proffered suggestions, nor would they, until some time after Sir George Grey had received a deputation from the Provincial Medical and Surgical Association. At last, the Council of the College have assented to such alterations in the College Charter as will go far to conciliate the wishes and desires of the provincial surgeons.

The following summary of the votes returned to the scrutators from the legally qualified members, will clearly show the wants of the profession:—For an amended

charter, 3915; for a new incorporation, 891. In Dr. Crisp's amendment it is set forth, in the first place, that the intention of this Association is for one faculty, upon the representative principle, which cannot be carried out by the proposed Charter of the Colleges. Now, in my opinion, the suggested alteration of the Council of the College of Surgeons, is a convincing proof that it may be accomplished. The statement above is an ample proof that the majority of the medical profession are opposed to a new incorporation. The recent suggested alterations in the charter will tend towards doing away with grades or classes.

I trust I may be permitted to make a few observations about the Benevolent Fund. No one can appreciate more than I do the engergy and benevolent feeling exhibited by its Treasurer; but I would wish to see the medical practitioners generally, connecting themselves with *County Benevolent Societies*, of which, I believe, there are many; and even where they do not exist, they are very easy of accomplishment. If medical practitioners have not the forethought and prudence to subscribe a small sum per annum to such societies, I am sorry to be compelled to say, they do not deserve the commiseration bestowed upon them; and it would not be our painful duty to listen to the many distressing cases which we hear annually reported, most of which have arisen from causes that might have been averted. I have solicited many to belong to the Surrey Benevolent Society, who have declined. Now, I maintain that all who have possessed the means, and would not subscribe, are not deserving of our sympathy.

If the medical profession generally would adopt the plan above suggested, there would be but little need of a Benevolent Fund attached to our Association. If each member of our Association were to make a small annual payment—say 5s.—it would answer all cases of emergency.

There is one other subject upon which I wish to make a few remarks, and that is, the Benevolent College. I have the honour and pleasure of knowing the projector, Mr. Propert; he deserves our warmest and best thanks for the most splendid and benevolent feeling he has displayed. There are very few like Mr. Propert who have the means and the opportunity, and capability of bringing such a project to maturity; after saying so much on my part, it will naturally be said, "it is all very fine talking, but I do not see your name, with the amount of your donation or subscription?" I am sorry to say that, *at present*, I (with many others) refrain from attaching my name to the list. I have expressed myself very strongly upon the subject of irregular practice, and I feel so warmly upon that subject that I have given up several valuable patients, rather than meet in consultation practitioners who practise in a manner not perfectly orthodox. I cannot consistently, or conscientiously, subscribe, until I see the committee a little more scrupulous about admitting medical subscribers who practise irregularly.

I must apologize for saying so much upon this subject, but I do so in justice to my own feelings.

I have the honour to be, Gentleman,

Your obedient servant,

GEORGE BOTTOMLEY.

Croydon, August 26, 1851.

ERRATA IN THE REPORT OF THE LATE MEETING AT BRIGHTON.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—In your report of my remarks on the Income-Tax I notice the following inaccuracy, which you will oblige me by correcting. Instead of "They put his name down at £20 instead of about £7 a year, and he allowed it to remain," it should have been "*Surcharged £20, which, at 7d. in the pound, would make nearly 12s. a year more; but he allowed it to remain.*"

Allow me here to state that I named the subject of the surcharge to the district surveyor or assessor. His reply was characteristic:—"They always did make a a trifling addition to the amount returned, as many little things might unintentionally be omitted." My remedy was to appeal. As this would probably have been inconvenient, or occasioned me to lose two or three hours in the best part of the day, during attendance on the Commissioners, I thought it better to submit to the injustice rather than purchase it at the sacrifice of time. Trifling as the individual exaction may appear, the sum annually collected from the professional and mercantile community by this mode of surcharge must, in the aggregate, amount to a pretty considerable sum over and above that sent in as the real returns of the parties.

I remain, yours obediently,

THOMAS SMITH.

Portland House, Cheltenham,
August 20, 1851.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—In my speech on quackery at the late Brighton meeting, I am reported to have said, "That we have a President of the College of Surgeons, a professed mesmerist, selected to deliver the Hunterian Address, and to examine quack medicines." As this is an error, and an unjust accusation, I trust you will do me the justice to state what I did say:—"The President of the London College of Physicians had appointed a professed mesmerist to deliver the *Harveian* Oration, and had in his pharmacologia analyzed quack medicines, and he says one of them (Dalby's carminative) is constructed upon philosophic principles."

I am, Sir, your obedient servant,

EDWARDS CRISP, M.D.

Parliament Street, August 23, 1851.

Medical Intelligence.

TESTIMONIAL TO S. A. PHILBRICK, ESQ.

On the 12th of August the members of the Colchester Medical Society assembled at the Cups Hotel, in celebration of their quarterly anniversary. This Society was established in 1774, for the purpose of forming a medical library and book-club, and the discussion of medical subjects. For the last nine years, Mr. Philbrick

has filled the honourable office of Secretary to the Society, since the resignation of Mr. Tomkin, of Witham, and in commemoration of his excellent services during that time, his colleagues determined on presenting him with a testimonial.

On the occasion in question, the members sat down to an excellent dinner, which elicited from the assembled guests the highest encomiums on the skill of the worthy host, Mr. George Chaplin. W. Waylen, Esq., presided, and S. A. Philbrick, Esq., by virtue of his office, filled the vice-chair; Dr. Duncan, Clark, Morris, Josh. Partridge, L. Brock, Taylor, Colchester; Manthorpe, Thorpe; Daniel and Fenn, Nayland; Grouse, Hadleigh; Peete, Manningtree; Gurdon, Boxford; Taylor, Colne; Symmonds, Bures; Meadowcroft, Bentley; Rodick and Sinclair, Halstead, forming the guests assembled. Numerous other gentlemen, members of the Society, in Colchester and neighbourhood, would have been amongst the party, had they not been mingling in festivities at the residence of W. W. Hawkins, Esq., Alresford Hall, and R. Turner's, Esq., Oliver's, near Colchester. After the usual loyal toasts had been duly honoured, and "Success to the Colchester Medical Society" drunk, the President, in the name of the Society, presented an elegant silver salver to Mr. Philbrick, as a memento of the value at which they had estimated his services as Secretary to their Society during the space of nine years.

This testimonial is exceedingly massive, weighing forty-eight ounces, and measuring fifteen inches and a half in diameter. It was manufactured by Messrs. Smyth, Nicholson, and Co., Duke Street, Lincoln's-Inn-fields, is in the Elizabethan pattern, handsomely engraved, and bears the following inscription :—

Presented to
Samuel Adolphus Philbrick, Esq., M.R.C.S.,
By the Members of the Colchester Medical Society,
As a testimonial of their thanks
For the zeal and courtesy with which he has performed the duties
of Honorary Secretary for a period of nine years,
August 12, A.D. 1851.

Mr. Philbrick very suitably acknowledged the receipt of the handsome testimonial presented to him by his medical colleagues. He felt a pride, he said, in being associated with those whom he had the pleasure of meeting on that festive occasion, and trusted that he should continue to perform his official duties, as far as his humble ability would allow, with credit to himself and honour to their Society.

After spending an exceedingly harmonious evening, the meeting broke up about ten o'clock.

COLLEGIAL PRIZES.

The Council of the Royal College of Surgeons have just announced the following to be the subject of the Jacksonian Prize for the year 1852, viz. :—"The Pathology and Treatment of Stricture of the Urethra." The prize is twenty guineas. The collegial triennial prize of fifty guineas, to be awarded at the commencement of the ensuing year, is, "On the Functions of the Several Parts of the Large Intestines in Animals of the Class Mammalia."

UNIVERSITY OF LONDON.

1851.—First Examination for the Degree of Bachelor of Medicine.

First Division.—Henry Briggs, University College; Alfred Carpenter, St. Thomas's Hospital; Henry V. Carter, St. George's Hospital; James Ekin, University College; Evan Evans, University College; William Henry Flower, University College; John Henry Gould, University College; Thos. Hillier, University College; Frederick John Money, St. Thomas's Hospital; Wm. Boyd Mushet, University College; Alfred Playne, King's College; Josiah Ramskill, Guy's Hospital; William Edward Robbs, King's College; William Roberts, University College; James Martin Roche, University College; J. W. de Tunzelmann, University College; John Newnham Winter, Guy's Hospital.

Second Division.—Walter Goodyer Barker, London Hospital; Erlin Clarke, King's College; James Doubleday, Guy's Hospital; Charles Reeves Evans, University College and Paris; Henry James Franks, Queen's College, Birmingham; Robt. Grundy, University College; Henry Staveley Thadeus King, King's College; William Langford, King's College; Elias Jones Roberts, Richmond Hospital, Dublin; Richard Wilkinson, King's College.

Examination for Honours.

Anatomy and Physiology.—Thomas Hillier (Exhibition and Gold Medal), University College; J. W. de Tunzelmann (Gold Medal), University College; William Roberts, University College; James Ekin, University College; William Edward Robbs, King's College; Josiah Ramskill, Guy's Hospital; Henry Vandyke Carter, St. George's Hospital; John Newnham Winter, Guy's Hospital.

Chemistry.—William Roberts (Exhibition and Gold Medal), University College; Josiah Ramskill (Gold Medal), Guy's Hospital; Thomas Hillier, University College; J. Woldemar de Tunzelmann, University College; Henry V. Carter, St. George's Hospital.

Materia Medica and Pharmaceutical Chemistry.—Josiah Ramskill (Exhibition and Gold Medal), Guy's Hospital; J. W. de Tunzelmann (Gold Medal), University College; Thomas Hillier, University College; William Boyd Mushet, University College; John Newnham Winter, Guy's Hospital; James Ekin, University College; Henry Briggs, University College; William Roberts, University College.

Structural and Physiological Botany.—J. W. de Tunzelmann (Gold Medal), University College; Thos. Hillier, University College; Josiah Ramskill, Guy's Hospital; Henry Briggs, University College; John Newnham Witner, Guy's Hospital.

ROYAL COLLEGE OF SURGEONS.

The Hunterian Museum will not be closed during the present month of September, in consequence of the number of foreign members of the profession now in London. The Library, however, is closed for one month, for the usual dusting and arrangement of the books, and will be reopened on the 1st of October.

THE FELLOWSHIP OF THE COLLEGE OF SURGEONS.

The following members of the college having undergone the necessary examinations for the Fellowship on the 4th and 6th inst., were admitted by the council on the 7th inst., Fellows of the Institution:—Messrs. Peter Redfern, M.D., Aberdeen, diploma dated August 18, 1843; and Edward Smith, M.D., St. John's Wood, (formerly of Birmingham), May 10, 1841.

SOCIETY OF APOTHECARIES.

Gentlemen admitted on Thursday, August 21st:—Thomas Cossar, Dorlington; Joseph Wm. Eastwood, Chesterfield, Derbyshire; John Langdon, Bampton, Devon; David Mickle, Leeds; John Oliver Rouse, Great Torrington, Devon.

OBITUARY.

August 19th, at his residence, 38, Burton Crescent, Dr. Pacifico, in his 85th year.

August 21st, at his residence in the East India Road, Francis Henry Beall, Esq., surgeon, R.N., in his 77th year.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

The great length of the report of the Meeting at Brighton prevented our inserting the annexed statement in its proper place in the business part of the Anniversary, and we now place it before our readers with other matters connected with the late meeting.

An Abstract Statement of the Income and Expenditure of the Provincial Medical and Surgical Association, from August 1st, 1849, to July 31st, 1850.

RECEIPTS.

	£	s	d
Balance from last year's account	16	2	6
Deighton & Co., for Advertizing & *Journal*	24	11	1
Churchill ditto and "Transactions" ...	88	12	8

ERRATA.

The following errata occurred in the report of the late Anniversary Meeting, owing to the reporter employed being unacquainted with the names of the several speakers, and also in consequence of one of his parcels, containing the greater portion of the manuscript, having been delayed in coming to us (by rail) until the day before publication, and of course preventing that careful revision it necessarily required on such an occasion:—

In the list of gentlemen who recorded their names in the book kept for that purpose, the name of "William Rose, Esq., High Wycombe, Bucks," was omitted to be copied into the *Journal*.

At page 458, col. 1, line 19, for "Mons. Phalari," *read* "Dr. Fabret, Physician to the Salpêtrière, Paris.

Page 461, in the discussion on the Income-tax, the name of "Mr. Lowe" is mentioned; in each instance *read* "Mr. Lord."

Page 472, col. 2, line 7, in place of "Mr. Domville read a paper on the causes of deafness," it should have been, "Mr. Toynbee read a paper entitled 'On the Nature and Treatment of those Diseases of the Ear which have hitherto been designated Otitis and Otorrhœa.'" (This paper will be published at length in the "Transactions.")

Page 475, for "Mons. Batelle," *read* "Mons. Battel, Administrateur des Hospices Civiles de Paris."

TO CORRESPONDENTS.

Communications have been received from Mr. Green, Dr. J. Conolly, Dr. Wardell, Dr. Lloyd Williams, Mr. Harrison, Dr. W. Davies, and Dr. Kirkman.

We are requested to announce that ten shillings have been forwarded by Mrs. Major Whitcomb, through Mr. Kelson, of Sevenoaks, in aid of the subscription to the relief of Mr. D. B., of Bedford.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

[Reported by MR. HENRY GREEN, Student.]

LECTURE VIII.

On the Morbid Conditions of the Heart.—(*Continued.*)

Gentlemen,—There are certain degenerations to which the heart is liable, in common with other structures. I shall only allude to them here in a very general manner, as they always arise from certain morbid conditions of the blood, and will be treated of at large under the section of diseases of the blood and capillary circulation. Meanwhile, as we are considering the various disorders to which the central organ is liable, it is not right that we should leave the subject without some reference to those localized, and yet constitutional affections. Rheumatism, as one of these, I have already dwelt upon at some length; but under the same category we may arrange mollification, with the fatty, the calcareous, and the cancerous degenerations.

Simple mollification, apart from any previous inflammatory action, is always due to an attenuated condition of the blood. In this state the walls of the heart, after death, are observed to be shrunken, wrinkled, and flaccid; easily torn by the nail, and rapidly running into putrefaction. It frequently exists under mere weakness and a lax habit of body, but is almost the invariable attendant upon diseases that break down the integrity of the blood, and render that fluid extraordinarily thin and uncoagulable; hence it is a symptom attendant upon typhus fever, scurvy, and delirium tremens. The motions and sounds of the heart, will, under these circumstances, become fainter than usual, and a small, rapid, fluttering pulse is likely to supervene, which will be much modified according to the different positions of the body. Where it is the result of these latter temporary causes, we must be content to wait till their departure. As the fever, or delirium tremens, or scurvy, pass off, the heart becomes restored to its natural state, and resumes its normal vigour. We have, therefore, only to treat the specific disease, according to the usual rules, and leave the heart to itself. Under a condition, however, of habitual or congenital debility, our efforts must be more persevering, and more direct. The object being the general solidification of the body, and improvement of the blood, our treatment must be partly medicinal, and partly dietetic. With this view, the powers of innervation must be roused, if necessary, by gentle and unexciting stimuli and tonics,—such as good old wine, and the various invigorating stomachic bitters; acid or alkaline reactions are to be neutralized as they arise; no exertions are to be undertaken to the extent of inducing fatigue; yet exercise must be regularly practised, and as much in the pure open air as possible. Quinine and iron will be indispensable from time to time, and sea-bathing at the proper season will also be advisable. The food must be strong and nutritious, and as dry as is consistent with comfort. Under-done beef and mutton, with bread and porter, will most likely be efficacious, when the stomach is once brought into a healthy state; although, previous to that, lighter food may be required, in which case a fair admixture of eggs, animal jellies, and milk, along with bread, will afford the greatest likelihood of supplying all the necessary elements. By a course of this kind, carried on through a long period, or even to the end of life, many a constitution may be rendered tolerably vigorous, and capable of entering into the usual business and enjoyments of society, which otherwise might have pined in misery, and sunk prematurely.

The fatty degeneration of the heart is to be accepted as one of the forms of scrofula, wherein the muscular fibres of the organ shrink and waste, as in a true atrophy, while their places are occupied by a deposition of sebaceous cells, incapable of carrying on the proper functions of muscular tissue. This condition is altogether similar to what occurs in the kidney or liver; but, instead of being attended with a general leanness, as these latter affections usually are, it is very often accompanied with full deposits of subcutaneous fat, especially when the muscular tissue of the heart is encroached upon from the surface inwards. One of the most apparent features in the disease, in such a case, is the slowness and faintness of the heart's action, as compared with the seeming robustness of the patient. He may be large and stout, and yet he will complain of a sense of feebleness, while the pulsations are felt as above described, as in the cases of Flewitt and Bull.

John Flewitt was a broad corpulent man, of about 45, and a brewer. He had been accustomed to work hard, and was allowed any amount of beer which he pleased to take. He had felt very short of breath for a considerable time; but what made him seek the hospital, was the supervention of asthmatic bronchitis. His countenance was dusky; the sonorous and sibilant wheezings were very loud; there was a distinct bulging with much dulness over the cardiac region, and the pulse was 82 and full; but both the impulse and sounds were very feeble; respiration, 36. The diagnosis was, from the fulness of the pulse, and the bulging, that there had been hypertrophy with dilatation; but that fatty degeneration had subsequently occurred, as indicated by the feebleness of the impulse and sounds. He had ipecacuanha and lobelia for his asthmatic bronchitis, and the heart was treated by occasional cuppings, and the administration of iodide of potassium, with bicarbonate of potassa. His diet was also so regulated as to check the formation of fat. Within one month, by these means, his pulmonary symptoms had quite disappeared, except some shortness of breath under exertion, and the respirations had descended to 26; the pulse also fell to the regular standard of 64, and became much more

forcible, both in its impulse and sounds. This patient was twice under us, and on both occasions had similar symptoms, followed by similar relief.

George Bull's case was, in its main feature, similar to this last; but the secondary results had assumed a different form. There were the same broad and corpulent figure, the same extensive dulness, and the same faintness of sounds and motions, but, instead of any pulmonary attack, he had chiefly been the victim of rheumatism, apparently from the general feebleness and stagnation of the circulation, which thereby offered facilities for the erroneous deposit of urinary salts. Besides the ordinary remedies for his rheumatism, which, of course, under the circumstances, proved very obstinate and recurrent, the treatment adopted for the state of the heart, consisted in a series of cuppings, and a course of Fowler's solution, with bicarbonate of potassa. He was two months in the hospital, and the last note entered in the ward journal concerning him was, that "the circulation had become considerably more forcible, and that he was free of pain, and altogether stronger in his general constitution."

In the case of Arnold, we had a similar faint action of the heart, with intermittent pulse; not, however, attended with any stoutness or rheumatism, but with asthmatic œdema of the lungs, ascites, and general anasarca. He was treated by occasional slight cuppings, and with muriate of iron, in combination with diuretics, leaving the hospital after one month without any dropsy or any intermission of the pulse; and altogether as vigorous as such a subject could be made, for he appeared also to have hob-nailed liver as the result of free potations of spirts, &c.

The general circulation, then, will be languid; and this will render the sufferer liable to secondary depositions, either solid or fluid, in the form of rheumatism or dropsy, or visceral congestions; while the stagnation at the lungs may bring on dyspnœa and cough. These latter symptoms were the chief sources of uneasiness to Flewitt, while Bull suffered from congestive rheumatism, and Arnold from dropsy, &c. The treatment will obviously consist in a cautious avoidance of the use of oil and fats, as well as a limited allowance of those farinaceous foods which contain its elementary principles. Lean meat, with ascescent vegetables, should form the staple of the diet; solvents of the fatty matter, and absorbents will be beneficially administered, such as the bicarbonate of potassa, in conjunction with the iodide; while, at the same time, stomachic bitters, and such tonics as iron or quinine, which improve the blood and give tone to the muscular fibre, should be employed with the further view of rebuilding the injured tissue. The drink had better consist of thin, yet alkaline, wines, such as hock or claret; or, in poorer persons, a saccharated solution of cream of tartar. If malt or spirituous liquors must be indulged in from a regard to long standing habits, these should either be weak spirits and water, or thin bitter ale. Very commonly indeed, the subjects of this complaint, as above illustrated, have been persons who have long indulged in draughts of ale, or dram-drinking, and the management of their dietary becomes, on that account, the more difficult. The patient, Flewitt, more especially, being a brewer, was exposed, of course, to all the habits of his occupation. He recovered, as you learn, from his most troublesome symptoms while under the discipline and treatment of the hospital; yet, most probably, he will be reverting to his former habits, and so re-inducing his ailments time after time. Indeed, he has already been twice in the hospital, and twice relieved as I have said, the interval having been about eight months.

The PHOSPHO-CALCAREOUS DEGENERATIONS, or DEPOSITS, are a still more formidable class of disease. What constitutes the habit of body which induces such an action is not known; but it has generally been found to be promoted in its development by scantiness of nutrition; though this scantiness of nutrition may often proceed as much from gluttony, coupled with indigestion, as from positive want of food. Hence those ossifications, as they have been called, are as common among the over-luxurious rich, as among the under-fed poor. An exception has been sometimes taken against the use of the word *ossification*, and proposals made to substitute the expression *calcification* instead. This, in many instances, appears to be highly desirable, for the proper osseous structure is never exhibited, except when there has been a previous development of cartilage which has gradually assumed the appearance of a bony net-work, intermixed with the ordinary cement of gelatine: whereas the amorphous depositions of the bony elements of the blood, as simple phosphate of lime, &c., in the fibrous and other tissues, afford no instance whatever of bone formation, but only of calcification. These deposits may occur as separate masses in the body of the heart, and they will then produce occasional manifestations of spasmodic action, accompanied with agonizing pain, such as arises in angina pectoris; or they may occur in the coronory arteries, leading secondarily to thinning and ulceration of some part of the parietes, with ultimate effusion of blood into the pericardium. This I witnessed in the body of Captain Haviside, at Bath, who died suddenly while sitting at table. The portion of the wall where the calcified artery was found had become thinner than the other parts, in consequence, most probably, of the locally-diminished and enfeebled circulation. After a time, the irritation of the foreign substance, acting on fibres constantly in motion, seemed to have brought on positive ulceration, and ultimately this had given way, and permitted the pericardium to become filled with blood. But the most common manifestations of this disease are to be found on the valves and at the roots of the chordæ tendineæ, giving rise to those obstructions and regurgitations of which I have already treated. Unless existing to a very serious extent, life may be protracted to an indefinite period; though with some degree of uneasiness, and a constant probability of death in the event of the invasion of any acute disease, especially of the lungs. Thus, in the old woman Twells, as well as in Sarah Billings and several others, where the calcareous attachments might be about the size of small teeth, and where the rough sounds were very distinct, there was no immediate

danger to life from that cause of itself. The accessions of pain, of inflammatory action, or of pulmonic engorgement, which might and did occasionally occur, were readily enough subdued by slight abstractions of blood and other temporary measures; and so, by due care, and freedom from heavy exertion, these patients were kept in tolerable comfort, so far as the circulation was concerned; for the ultimate agonies and death of Twells were due to cancer of the pylorus, and not to her valvular disease. Indeed, there are many persons to be found with very marked rough sounds, both single and double, who, while they must suffer certain constitutional derangements, are yet almost unconscious of them, and feel surprised if they learn that they have got cardiac disease. But this cannot be when the obstruction, waxing greater and greater, finally induces hypertrophy, with dilatation. Even though no dropsy, nor pulmonic congestion occur for a considerable time, as we have witnessed in sundry cases of this kind, still the local and general uneasiness becomes too oppressive to be concealed from the patient himself, and he feels his languor, debility, and entire faintness to be, in remarkable contrast to that heavy hammer-like stroke of the central organ as it beats against his ribs in the silence of night, shaking his whole frame and ringing in his ears, and perhaps, also, making him conscious of that harsh, croaking, or grating sound, which seems to afford physical proof of an attrition that is wasting his body, as it were, at the centre. This state of things was well illustrated in the cases of Shaw and Anderson, already related. In such plight the patient places himself under the advice of some eminent physician, and, not knowing the real nature of the disorganization that has taken place, feels surprised that so little success attends the medical treatment. The same feature sometimes attends other mortal diseases, even in the last stage, such as pulmonary consumption, when the sufferer happens to be of a sanguine temperament. After their cough may be subdued, and some other of the more troublesome symptoms, they will frequently observe that if you could *only* relieve the breathing a little and give them some strength, they would be quite well. This was the constant observation of John Cox, and you will hear it from many others—nay, they will sometimes leave the hospital, insisting that they are quite well, except as to this shortness of breathing and weakness, which they calculate will leave them under good diet and fresh country air. Strange, and unhappy delusion!

The symptoms that characterise these phosphatic valvular obstructions have already been dwelt upon. Where they are of recent occurrence there may only be a single blowing sound heard, or, if double, the sounds may be very gentle. According to the size and roughness of the masses, these sounds will become harsher and harsher; and, when hypertrophy and dilatation have supervened, there will also be a heavy and forcible impulse, with increased dulness under percussion. The particular valves diseased will be ascertained by the situation in which the sounds are loudest; and, if the secondary hypertrophy be very great in the right side of the heart, the stroke will be felt impinging upon a point below and to the right of the sternum. The secondary effects upon the general and pulmonic circulation have already been discussed, and the changes that take place on the arterial and jugular pulses have also been pointed out. All these, indeed, are necessary pathological results, such as might be inferred from the common principles of physiology, and which must be viewed in that light and bearing, and not as detached or empirical signs. Thus the obstruction to the passage of blood from the left side of the heart, while it makes the general circulation languid, keeps up a constant engorgement of the lungs. The engorgement at the lungs prevents the flow of blood from the right side. The engorgement of the right ventricle and auricle maintains a constant stagnation of the venous and absorbent systems, which necessarily leads to the deposit of serum from the capillaries, and the over-abundance of black vitiated blood, in every organ of the body. Hence congested kidneys, livers, bowels, &c.; and hence dropsies of every description throughout the cavities and in the areolar tissue of the whole body;—hence faintness, anæmia, and universal wasting of the natural tissues, except, perhaps, in the walls of the ventricles themselves, which struggle violently to the last.

The treatment for the local affection itself throughout all its stages, but especially when any temporary inflammation seems to arise from the presence of the foreign matter, is chiefly a repeated abstraction of limited quantities of blood by leeches or cupping, or a series of small blisters, while irritability is subdued by a belladonna plaster, and the internal use of conium, digitalis, or hydrocyanic acid. The strength, at the same time, must be sustained by mild nutrient diet; and perfect quietude of body and mind must be enforced. The employment of nitric or muriatic acid might possibly be of some service in counteracting and dissolving the deposits; but on this head I have no facts to offer. The disease, without doubt, partly originates in the blood; but still there are certain coincident conditions in the solid parts which tend to localise it. Thus, it is always found in the current of the arterial circulation; and instead of the deposit being universal throughout the tissues, it is commonly agglomerated into masses, as on the aortic valves of Shaw, where they were as large as half a walnut, and on those of Twells, where they were the size of small human teeth, or else precipitated in the form of patches or scales, with definite borders, as in the case of John Anderson and others. This fact of agglomeration proves that, while the calcareous salt may exist in equal proportion throughout the blood, there are yet certain conditions at certain points which act as centres of attraction to it. What those conditions are is an useful and important subject of investigation, the knowledge of which might greatly improve our modes of treatment. Perhaps, however, it may be too minute to come under the cognizance of our senses; and, unfortunately, if once any salt of this kind becomes deposited, even in the smallest amount, it always forms an active nucleus for the accumulation of such like materials as may exist in the surrounding fluids, as in the case of vesicular and renal calculi, and other earthy

and saline deposits. The abstractions of blood from the cardiac region help to relieve the lungs and whole body, as well as the heart; but they may be required to be practised for congestion in other organs, especially the brain, liver, or kidneys; and it need only be added, that dropsies are to be opposed by purgatives, diuretics, or sudorifics, according as the respective emunctories are in a condition to bear their action. But the grand general rule, under all circumstances, is to make the circulation and respiration as easy as possible, and keep them so. (This has proved successful in the cases of Charlotte Wheeler, now once more in the hospital, and several others.) If not too far gone, such cases, indeed, afford much room for the satisfactory efforts of the physician, not, indeed, as regards a perfect cure, but certainly with respect to a comparatively easy and prolonged life, provided the patient be not compelled by his circumstances to follow a laborious or exciting occupation, or be too stupidly obstinate to discipline himself in any way whatever.

The malignant formations of SCIRRHUS OR CANCER, in their varied forms, are not common in the heart; and, as the general principles that govern such heterologous deposits will be treated of separately under the head of blood diseases, I shall not at present enter into them at all. They are the same whether they occur in the heart or anywhere else, and therefore require no special comment on account of their locality. It is sufficient to say that, from the rareness of the event, I am precluded from making any observations founded on practical experience, and that medical literature does little to fill up the blank. It has been asserted, and, from abstract reasoning, I should think the assertion true, that cancer cordis produces all the range of symptoms generalized under the name of angina pectoris. As to treatment, as there is nothing known with any certainty as to the nature and curation of such an affection in less vital and more visible parts, so we know less than nothing (so to speak) in regard to these attacks on such an organ as the heart. There is required, on this subject of malignant action, a most combined and systematic study amongst physicians and physiologists; and, until ardent and persevering minds are brought into freer and more immediate intercommunication with each other, and with practical men, little progress will be made; because the subjects of study are so few and so isolated that few individuals of themselves can have a sufficient basis of fact for generalization, unless they be helped out by the observation and experience of others. A metropolitan hospital for malignant disease would be one of the greatest means of benefiting mankind. Nay, such a hospital might be open for the reception of all so-called incurable cases, only admissible, however, upon the certificate of a body of hospital physicians and surgeons, or other responsible and official persons; and then the statistics of such an institution would be truly instructive and beneficial, as they might ultimately prove the means of removing a few more formidable and mortal names from our nosological black-list.*

* I am now glad to learn that a "Free Hospital for Cancer" does exist in Cannon Street, London.—D. N.

As to CARDIAC MALFORMATIONS, such as the absence of one ventricle, or of one ventricle and auricle, or the continuance of the fœtal intercommunication of the two sides by means of the foramen ovale, and ductus arteriosus, each of them is not so much a positive disease, as a mere arrest of development, and therefore does not properly come under the practice of physic, but rather under the notabilia of physiology. Such anatomical deficiencies can no more be supplied than we can supply horns to hornless cattle, or beards to hairless men, and therefore they come not under any hospital notice. As to the secondary inconveniences that may arise from the imperfect oxygenation of the blood accompanying these malformations, they must be treated in accordance with the principles laid down for their management in other parts of these lectures, from whatever cause they proceed.

ON THE PROGRESS OF PUBLIC HYGIÈNE AND SANITARY LEGISLATION IN ENGLAND,

AND THE ADVANTAGES TO BE DERIVED FROM THEIR FURTHER EXTENSION.

By J. INGHAM IKIN, Esq.,

Fellow of the Royal College of Surgeons of England, and Lecturer on Anatomy and Physiology in the Leeds School of Medicine, etc.

Read before the Leeds Philosophical Society, March, 1851.

THE importance of my subject must be admitted by all, though some may question its interest and disregard the study of it, considering such topics fit only for the study and attention of the mere official or professional members of society. That such an impression exists so generally is a matter for regret, as it prevents the due appreciation of the labours of many scientific but unobtrusive men, as well as practical statesmen and noble-minded philanthropists.

It is really curious to observe how tardy is the public mind to take up and interest itself about really important social improvements, whilst often some political question of no great practical moment, or one of a complicated theological character possesses an absorbing interest; gradually, however, it is to be hoped, and steadily, will such questions as those involved under the head of public hygiène, steal a march upon mere contoversial topics, and as science, experience, and observation must in the long run supersede ignorance, superstition, and credulity, so will questions like the one we propose to discuss to night, become every year more and more appreciated, from their bearing upon the interest and welfare of all classes of a densely-peopled country like our own.

State medicine, medical police, and hygiène, are terms which have been used synonymously, and defined to express the art or science which has for its object the application of physiological and medical science, to securing the well being and amelioration of society—

that is, of improving the sanitary condition of the people, and promoting the health, ease, and welfare of the human race, especially that portion of it doomed to live in towns. Indeed, as has been well said by a writer in the *Quarterly Review*, in an article "On Water and its Sources," "Physiological and chemical science have now demonstrated beyond all contradiction, that the mortality of towns and the premature degradation of the townsman's body, year by year, is the result of minute and almost, at the time, unappreciable impairment occasioned by a multitude of noxious influences, and sometimes even collectively inadequate to produce violent and definite disease, but not on that account less fatal in their ulterior effects; for, as when litmus paper is dipped in acid it turns red, when a *rosy* child is dipped in town air, and kept in it for some time it turns *white*. The first change it is true is instantaneous, but the second is not less certain, though it may take months or years to accomplish, and is certain in the long run." I need scarcely add that such deleterious influences are often rapidly and wonderfully checked by removal to the sea-side, or by breathing pure bracing country air; the appearance alone soon indicates this in a striking manner. In using the term hygiène, you are not to suppose as many absurdly do, that it has reference to and is merely connected with mere matters of diet, regimen, gymnastics, and the routine regulations for the attention of the valetudinarian. Important as are diet regimen, clothing, variations in climate, exercise, &c., there are branches of hygiène more correctly confined to the division termed private hygiène. "The public are apt to think," says the *British and Foreign Review*,* a journal to which I shall have to refer hereafter in terms of the highest commendation for its services in the cause of the progress of public hygiène, "that medical police, implies nothing more than the seizure of stinking fish, or the detection of unsound meat, the adulteration of beer, &c., or at most a fear-spreading contrivance, termed a Board of Health, brought into action when the cholera rages." But with the definition given above, our subject takes another higher and more comprehensive scope of inquiry, but till the last fifteen or twenty years at most, it has been little cultivated in England, and even now, notwithstanding the numerous detached essays and treatises of the different branches of private hygiène, we do not possess a comprehensive work on State hygiène, although abundance of materials of a most valuable nature exists in the various Parliamentary reports to which I shall have occasion to allude, and which, fortunately, from having access to the Town Clerk's† library, I am able to obtain and peruse at leisure, from which an excellent work might be composed. In France, Germany, and America, State hygiène constitutes a separate chair in the universities and colleges, and numerous essays and treatises on the subject, from our continental neighbours, are constantly brought before our notice in the standard reviews; indeed our neglect and indifference have called forth the censure of foreign authors, and the laborious investigations and efforts of a numerous class amongst ourselves, are now only beginning to be appreciated, and their suggestions and remedies are now only in the course of being partially carried out.

Dr. Kilgour* well puts the importance of this question to all classes of society:—"To the legislator and the political philosopher, as physicians of the State, the knowledge of this science is imperative. In modern times the interference of Government, till within the last few years, has been confined to laying down such regulations as were supposed to be best adapted for preventing the entry of the plague or cholera into the country, or removing, by the indictment of nuisances, those sources of disease which were too apparent and flagrant to be overlooked, though, as we shall have occasion to repeat, the law in this respect, either in the local or general acts, is almost impotent. It is true quarantine may have been enforced, and on extraordinary occasions the sick are separated, compulsorily, from the healthy. Adequate means are not yet applied to improve the strength, and preserve the health of the community, by preventing the naturally strong, as well as the weak, from becoming exposed to those influences which would exercise an injurious effect upon the body. It is the principle of life itself which is the care of the State, and happily for us, and in accordance with Christian precept, life is as valuable, and as deserving of protection, when tenanting a weak and deformed body, as when encased in the most Herculean power, whether clad in rags or clothed in purple and fine linen. The most miserable object of corporeal deformity may do the State as good service as he who can perform the most laborious work of husbandry, or can march, fully accoutred, to repel the nation's foes; and he who is strong and valiant may, nevertheless, owe his subsistence to the crooked and feeble citizen who faints at the sight of a drawn sword; still there is no reason why a weak and sickly race should be allowed to spread, and the old expression that the sound mind is to be found connected with the sound body, is, as a general rule, indisputable. The ancient legislator, we read, laid down the most strict laws for rearing a hardy and vigorous people. They made, however, physical force paramount to everything else, and looked upon the strongest man as the best citizen, and considering the state of society at the time this was necessary. Where nations are small and close to each other, and where mutual jealousies and antipathies are bringing them into constant collision, powerful and expert soldiers were required, and every citizen must be a soldier. The cultivation, therefore, of the physical power was incorporated with the well-being and freedom of the nation, and was carefully provided for by the laws. The deformed and weakly offspring were troublesome in the rearing, and useless when arrived at manhood. The principal care was devoted to the

* In an article on medical police, October, 1842.

† John Arthur Ikin, Esq.

* *Vide* Kilgour's treatise on "Private Hygiene, and Lectures on the Ordinary Agents of Life." A very pleasantly-written, agreeable, and instructive work. It does not, however, profess to treat of public hygiène at any length.

healthy, and the death of the weakly and deformed was received without regret. It is still the same where hostile and savage nations exist. With them, altbough there are no codes of laws, yet the impossibility of procuring food, except by the most laborions bodily exertions, begets an active and powerful race of men, (*e.g.*, the North-American Indians,) and fits them, (as well as training in the gymnasium, or fighting like gladiators,) for opposing their foes. But if policy made the Greeks desirous of a race possessed of great physical power, humanity as well as policy, not to speak of the higher motive which we have the privilege of being influenced by, teaches us to preserve the weakly, cure the sick, and provide for the worst affliction of all—malady of the mind. The best gymnasium of antiquity sinks into insignificance before the pile which individual or public beneficence has raised for receiving the sick, the maimed, and the imbecile, for furnishing to them the means of recovery and alleviation, and for sending them back sound and useful members of society. What are the baths of Caracalla or of Dioclesian, compared to a Guy's Hospital or Bartholomew's, or the Asylum at Hanwell?" What the skill and labours of a Galen and a Celsus to the discoveries of a Jenner, and the labours of a Howard?"

Experience has demonstrated the superior value of modern practice, which, though imperfect and capable of immense extension and improvement, as the public records I shall have to refer to and commend, abundantly testify; for we find that, notwithstanding the greater number of diseases of a contagious nature to which mankind are exposed;—notwithstanding the greater number of diseases to which, from their luxurious habits and artificial manners of life the higher classes are liable;—notwithstanding the close and continuous labour to which so many of the poorer classes are obliged to submit, in order to obtain a livelihood;—notwithstanding the greater size of our cities and towns, and the noxious murky atmosphere breathed by the inhabitants of our manufacturing and populous cities, the average duration of life is much higher than ever it was in Greece or Rome. In England the average of life is about 45 years, whilst in ancient Rome it was only about 30. To what is this owing? It is to our feeding the hungry, clothing the naked, and aiding the sick and broken-hearted;—to our founding useful charities and associations for the aged and infirm, as well as establishing hospitals for the sick, and preventing, to some extent, the intercourse of the contagious with the healthy;—to our obeying to some extent, though I must add only in an imperfect and inefficient manner, the laws of hygiène;—by inculcating and practising cleanliness;—by procuring an adequate supply of water, and being able to furnish the masses with cheap food, clothing, and fuel, adapted to our variable climate;—by attending, in an increased (though as yet very inadequate) degree to ventilation, and improving the construction of mills, work-shops, &c.;—to removing nuisances, and preventing miasmata from decaying vegetable and animal matter; attention to all of which circumstances tends to prolong life, and promote the health, well-being, and comfort of the community. No subject connected with hygiène has been more difficult effectually to carry out in practice than the ventilation of public buildings, churches, chapels, museums, &c., as well as that of dwellings and work-shops, especially amongst the lower orders.

I shall conclude these introductory remarks by appending, in a few lines, a statement which must demonstrate to the satisfaction of every one the necessity that exists of procuring a due supply of fresh air for the requirements of the living economy.

Suppose "we take the ordinary computation of twenty cubic inches of air being drawn into the lungs at each inspiration, and that there are about twenty respirations in a minute, then 333 cubic feet, or thirty-three hogsheads are used by each person per diem. Not less than between ten and twelve cubic feet of carbonic acid are therefore evolved in the course of twenty-four hours, a quantity which will be found to contain at least six ounces of solid carbon! The consideration of this fact alone must suffice to show the extreme importance of there being no impediment to the due exercise of the function of respiration, and prepares us at once for the pernicious results that inevitably attend upon the breathing of an atmosphere which does not enable the system to remove its self-generated poison. The retention or inadequate discharge of the carbonic acid, besides the more direct effects of oppression, ennui, loss of appetite, and greatly-impaired muscular energy, renders the body more prone to the every form of diseased action, (in the same way as extreme fatigue and continued fainting,) and far less capable of resisting the influence of baneful agencies from without."*

The title of my paper implies two divisions of the subject;—the history and progress of public hygiène. and the desirability of its extension in accordance with our present knowledge, and agreeably to the testimony of a numerous class of scientific as well as practical observers. I shall avoid detail as much as possible, and confine myself (in the mere general sketch which I can alone take of such an extensive question in a single paper) to the grand features of the case, hoping in this way the better to keep up your attention, and the more forcibly to impress upon your mind the important bearing of my subject on the general well-being of society. And if I can succeed in furnishing you with some small degree of information, and in pointing out to you the sources from which further knowledge may be gained, and if I can cause the labours of others to be more duly appreciated, and give you some idea of the extent of these labours and of the praiseworthy exertions of the modern promoters of public hygiène, I shall not have cause to regret having selected this subject for our attention and discussion this evening. It is a subject in which I have felt, I may say, a deep interest ever since I entered the medical profession, and the importance of which I have frequently dwelt upon in public lectures and on other occasions; feeling convinced that the

* *Vide* British and Foreign Medico-Chirurgical Review for June, 1851.

principles of hygiènic science were as little understood as appreciated by the public at large; and feeling certain—and as all sincere friends of medical science must feel—that as these principles were more generally known, so would they be acted upon, longevity would be promoted, civilization extended, and happiness diffused. If medical men were influenced merely by narrow-minded, selfish, or pecuniary motives they would not wish to see public hygiène make any progress. But, to the honour of our profession, selfishness is not its leading principle; for, as a body, I may fearlessly state we are always found willing to risk our lives in the prosecution of any path in which duty or the claims of suffering humanity may lead us. We deal more generously to the public than the public are in the habit of dealing with us;—we are ever willing to give information on matters of which the majority must necessarily be ignorant. Unlike the charlatan, the empiric, and the unworthy and degraded members of our body, (for in all professions and classes there are such, alas! to be found,) we deal in no secrets, for we know our science cannot be gainsayed or overturned, though it may be misapplied and brought into disrepute. Knowing that physiology and anatomy, the handiwork of the great author of all things, are the groundwork of our art, and that the rules of the one, and the facts of the other, cannot be controverted, refuted, or explained away like the edicts of the lawyer, or the doctrines of the theologician.

In bringing before you a hasty glance of the progress of hygiène up to the present time, (for it is still in its infancy,) it is a proud and gratifying fact to find that this progress—this development, so to speak, of a new science, has been principally (I do not say altogether) effected by members of the medical profession. We may trace hygiènic institutions strictly speaking, as far back, in this country, as the time of the Crusades, for it is to them we are indebted (according to Kilgour) "for the institutions for the separation of the sick from the healthy, and for the reception and curing of the diseased. The irruption of the barbarians into the Roman territories made an end of those habits and customs which had been considered requisite for preserving the health of an enervated and luxurious people. There was no occasion for a gymnasium to those whose very existence depended on constant labour and exertion. Their whole life was a struggle, and the broad canopy of heaven the covering of their gymnasium. They transmitted their powerful bodies and their warlike dispositions to their sons, and the almost continual wars kept aloof enervating luxury. When the descendants of these same barbarians assumed the titles of Crusaders, and joined the holy army—when they buckled on their armour to fight for the Holy Land, although often beaten back and foiled in their object, yet out of this failure came good; they returned furnished with the laws of the East, and with many of the practices, customs, and institutions of the enemy. The enthusiasts brought with them the leprosy, but they brought with them the antidote as well as the bane. The disease soon disappeared, probably more from the change of climate than from skilful treatment, but the 'maladeries' remained, as the seed from which sprang the lazarettoes, the hospitals, and the infirmaries. In later times, charities and hospitals of every kind have been established along with the extensively useful institutions, the public town hospitals and dispensaries, as well as the monastries and nunneries of old, brought harbour for the sick for a time, and sisters of charity might do much in their way, and what are these compared to the nurseries and noble hospitals of the present day. And where, may I ask, but in old England, can you see members of a learned profession giving their services gratuitously to charities and public institutions of every description for the relief of sickness and disease? The science of medicine according as it has marched forward in its career of improvement, has picked up the invalid and made him sound, when formerly he would have been left by the way side as incurable; (and many good Samaritans now exist in our body, who conceal their charity from the world, and boast not of the cures they have performed.) Thousands are now sent back to society from the hands of the physician and surgeon, and from these noble institutions, who would formerly have been allowed to pass uncared for to the grave. It was from the East—from Constantinople, that Lady Mary Wortly Montague brought the first preventative of the spread of small-pox—the inoculation, to be succeded by that of the illustrious Jenner—vaccination, which has been calculated to have added nearly a *fifth* to the human race. Another child of England, too, spread his love for his fellow-men, over the civilized world. Howard saw in our prisons but dens of misery, disease, and loathsomeness, too frequently a grave for those confined, and a hot-bed of infection for those who visited them." Howard taught that the object of a prison, (the same as Pinel did for Asylums,) formerly so wilfully mismanaged, was not to confirm its inmate in his ways but to send him back an improved member of society; and he showed that cleanliness and mercy were compatible with security and punishment.

Laws relating to the management of drainage, though inadequate, have existed in England from a very early period. The crown was first invested with authority to determine the areas of foundations for drainage, as well as to constitute the authorities which should have power to act for the public protection within them. It is (*vide* second Report of Commissioners of Inquiry into the state of large towns) apparent that serious attention was given to works of drainage from the earliest period of our constitutional history. The earliest fundamental provisions have been laid upon the footing that such works, as well as measures for the maintenance of the free flow of running waters, were of general, public, and national, rather than of exclusively local, consideration. Special commissions on the subject of drainage and sewers were very early in our history. Indeed the 16 c. of Magna Charta is a defence of the public rights against the encroachment of private interests upon the great public water courses. In the reign of Henry III., a special Commission was issued to regulate the laws and customs of Romney Marsh.

These commissions extended to the formation of new roads and maintenance of old ones as well. In the third year of Henry IV., there was a commission for providing the means of carrying pure water to the inhabitants of Kingston-upon-Hull, as well as for draining that town and removing impure sea or marsh water. The Commission recites "that there appears to be need in those days of great charges and expenses for the protection of the same town against the force of the water aforesaid; and so as well as on account of charges and expenses of this kind, there daily arising to be sustained and supported, so that sweet water is not had, coming and flowing to that town except only by boats, and that at sumptuous cost, whereby the poor inhabitants of the town aforesaid, in large numbers every year, during the summer time, of necessity, on account of the scarcity and dearness of water of this kind, depart from the same town, and renounce and avoid it, to the injury of the town aforesaid; and in process of time to the final destruction of the same, unless a suitable and speedy remedy in this matter be speedily applied," &c. Here then we have an early example of legislation for the supply of water to towns.

With regard to the history of water-supply for London, a few remarks will suffice, but such an important matter we cannot pass over. According to a very clever article in the *Quarterly Review*, for September, 1850, (to which I was referred by Mr. West,* an authority in these matters which will amply repay the perusal, and from which, had time allowed, I might have extracted much useful matter in elucidation of this now really fashionable question.) The first or primitive water epoch (for London) includes the whole lapse of centuries preceding 1235. During this long period no artificial arrangements were employed in the metropolis for the collection or distribution of water, which the Londoners fetched, like simple villagers, with pitcher and pail from the neighbouring streams, in the same way as their perished progenitors had done, or "stooped with hollowed hand to drink." During the second period, which we may date from the completion of the Tyburn conduit in 1235, art was first employed to utilise the gifts or to correct the local deficiencies of the supply by storing in tanks the water of adjacent springs, or bringing through conduits ampler currents from afar.† During the third period, commencing from the plan of Peter Mons, in 1580, these conduits were extended to the very houses of the citizens, by branching ducts, through which the downward flowing river water was made to force itself up by tidal wheels and pumps, so as to sketch out for the first time a true circulating water system, with its central heart, arteries, and capillary ramifications. During the fourth period, dating from 1782, the water service of London extended concurrently with all the main branches of industrial art, was gradually transformed by the invention of the steam engine, which impelled the circulating fluid so powerfully through its channels, that the wood of which these were made were inadequate to sustain the increased hydraulic pressure, and was superseded by the introduction of cast iron. During the fifth period, which dates from the establishment of the first London filter, in 1829, and which seems still to be in its infancy, (as an epoch), the attention of engineers and chemists has been more and more strongly directed to the artificial purification of the water, previously supplied either in a strongly impregnated state or from an impure source. With the last three periods of this gradual evolution the history of the London Water Companies is naturally interwoven, and the monopolies of which will now be no longer allowed to exist, and London, which should be our model in industrial improvement and Sanitary Reform, must not submit to suffer from the inadequate quantity, quality, and cost of its water.

This subject, from the time of the publication of the reports and evidence of water-supply in 1821, 1828, 1834, and 1840, up to the present year, has repeatedly occupied the attention of Parliament, and the inhabitants of large towns have oft, like London, had to seek its aid, and incur much expense and opposition in order to procure that necessary of life—that boon of heaven—a cup of pure cold water, which even in these luxurious and flourishing times has oft to be sought for in vain, and may now even fairly be estimated as a pearl of great price. Filtering, boiling, chemical reagents, and all other artificial means that the ingenuity and skill of man and science can invent, cannot render any supply of water equal to that of a pure unadulterated spring. The water-drinking part of the community would, doubtless, find their opinions and habits more extensively adopted, could they even supply a genuine article. The products of the vine, and that of the barleycorn, would then become less generally patronised; but unfortunately for the public genuine articles in the form of food and drinks are rather the exception than the rule, as we shall have occasion to prove before concluding this paper. Adulterated tea and coffee are often quite as injurious to the health as any spirituous beverage. But to proceed with the immediate subject before us. With regard to drainage and sewerage previously to the statute of Henry VIII., (a law still in force,) the commissioners of sewers were named directly by the Crown. By this statute it was provided that they should be named by the Lord Chancellor, the two Chief Justices, and the Lord Treasurer. This act governed the metropolis and about eighty rural districts. It also enacts that commissioners of sewers should be appointed for other parts in this section," for making laws, decrees, and ordinances. It gave also powers to execute works, and levy rates, &c. In modern times, however, the working and government of these commissioners is not in force.

As medical science became more cultivated, hygienic knowledge was more diffused; and we find an infinity of local acts and municipal bye-laws providing for the supply of water and the sewerage of towns, the cleansing

* Mr. West, our eminent chemist, I much regret to say, has just died, whilst this paper is printing.

† Considering our early connection with the Roman Empire, famed for its gigantic aquaducts and sewers, it is curious more adequate means, with regard to a supply of water, were not undertaken.—I.

of streets, the discovery and destruction of unwholesome food and drink, &c. "Boards of health were established in Ireland, but failed in achieving any permanent good. The most important authorities for removing nuisances were vested in court's leet. Juries were empannelled at these courts, and authorised to perambulate districts, and judge of nuisances upon the view. These 'annoyance juries' as they were named, have been discontinued in many parts of the country since the Poor-law came into operation; and they were not found effective, from the incompetent class of persons selected to serve upon them, and the Boards of Health which were instituted to replace them were little better."*

The inadequacy of these acts, and their inapplicability to the present condition of our country, have led to the necessity of amending the laws, and passing more efficient ones, such as the numerous local improvement acts, as the one in Leeds, for example—an act much in advance of those for most other towns, though very inadequately carried out as yet; bills for the sewerage of large towns, powers to appoint local surveyors, inspectors of nuisances, and, lastly, to the passing of the Health of Towns' Bill, and the establishment of a Central Board of Health. The benefits to be obtained from these measures are still partial, but undoubtedly they are extending, and will extend in a few years still more rapidly, and thus tend in a remarkable degree to improve the sanitary condition of the people.

It is unnecessary, and it would be tedious, to trace the early laws relating to quarantine, carried out for the supposed prevention of the plague and Asiatic cholera, if the present theory were generally, though not universally adopted, that such laws are totally inefficacious, and founded on mistaken data, it testifies on what mistaken views our Legislature has acted with regard to them. We must not, however, speak too confidently about the propriety of the total abolition of quarantine laws and other sanitary precautions of this kind.

It is only then by degrees, and in course of time, and as circumstances rendered interference more necessary, that we find State hygiène carried into practice, and that the principles of medical police have been acted upon, and spread, and progressed in England. The earliest hygiènic measures being the establishment of hospitals (certainly 600 years ago) not only for the wounded, but for the sick and weakly; early laws regulating and providing for the supply of water; laws for the regulation of water-courses, drainage, and sewerage; quarantine laws against supposed contagious disorders; the establishment of fever-hospitals, and those for cases of small-pox; the introduction of the practice of innoculation; the discovery, by Jenner, of that grand and incalculable boon to mankind—vaccination. To these we must in justice add Sir Humphrey Davey's beautiful life-preserving invention, the "Safety Lamp;" also our improved method of treating the insane, and managing asylums, for abolishing restraint and coercive measures are quite of recent date, indeed we arrive now at a new stage in the progress of hygiène, and come to that period from whence we may fairly date its general culture as an important branch of study, and as being important both in a political as well as medical point of view. We arrive at our own day, and have to speak of the labours of the living, or of those who are either living, or have only lately quitted their sphere of usefulness. Amongst the latter we must enumerate the late Sir John Sinclair, who devoted his life to carrying out useful practical improvements, and always had in view the grand question of the best means of preserving health, and of procuring longevity. In tracing the progress of public hygiène, also, I must not omit the name of Captain Cook, who paid such attention to the health of his crew, that in his three years' voyage round the world he only lost one man. To this great navigator we are indebted for teaching us that human life is as safe from disease on board of ship as on shore. The improvement of naval hygiène, and the introduction of more wholesome diet, and use of lemon juice to prevent scurvy, are due to him; and more recently, to the able and zealous naval medical officer, Sir William Burnet, Director-General of the Medical Department of the Navy, who has rendered important services to his country for his management and improvement of the health of the navy, by attention to food, clothing, bedding, cleanliness, ventilation, climate, intemperance malaria, &c. His valuable discovery, also, of the properties of chloride of zinc in destroying the odour of bilge-water, killing vermin, and preserving timber, canvass, cordage, and ships' stores, deserves mention here. It does not emit the disagreeable effluvia which are to many so strong an objection to the use of chloride of zinc, (a French discovery of vast practical utility,) nitrous gas, &c.

Sir William Burnet, early in his career, according to a recent account of his life and labours in the *Lancet*, was forcibly struck with the insufficiency of the returns then in use to show the nature and extent of sickness and disease existing in the naval medical establishments on shore, as well as in the service afloat, he therefore first required from the medical officers periodical returns to show the extent of the particular class of diseases in each hospital or ships in every station, and also the number of deaths from each disease separately. These regulations have been of great advantage in the preparation of statistics, to show the effect of remedial systems pursued, both past and present, and from this source under the Director-General's superintendence, most elaborate and interesting statistical reports have been published and still continue in progress. He succeeded in establishing a large naval hospital at Chatham, instead of employing hospital ships at that port. He confirmed the management of the Asylum for naval lunatics at Haslar. The codes of instructions relating to naval medical service he revived and constructed afresh. Libraries and museums have been formed on an inexpensive plan at his suggestion. He established a very important alteration—a sick mess in Her Majesty's ships. The effect of all these improvements—of these labours of Sir William Burnet, are satisfactorily shown in the decrease of those frightful outbreaks of sickness

* *Vide* British and Foreign Medical Review.

with which the crews of Her Majesty's ships were formerly so often visited.

Many other names in connection with the health of the navy, particularly the valuable statistical reports of the health of the navy by Drs. Wilson and Bryson, might be enumerated, but I must forbear; the present condition of the navy—the almost entire absence of scurvy—the improvement on the health and habits of the sailor abundantly testify with what success the rules of hygiène have been here carried out.

[To be continued.]

ON UTERINE HÆMORRHAGE.

By W. NEWNHAM, Esq., Farnham.

It is admitted on all hands that uterine hæmorrhage is accompanied by the most trying circumstances which are incident to professional life, and as these are often requiring the most prompt and determined assistance, as well as the nicest discrimination in the appropriation of remedies, it cannot be out of place frequently to review any of the great principles involved. I shall avail myself of the narration of two recent cases, in order to append some remarks upon these principles.

I was consulted on the 12th of April last by a lady in the sixth month of pregnancy, for an attack of uterine hæmorrhage. She had been much alarmed the previous day in consequence of the pony she was driving running away, and kicking; and an appearance of discharge, which she had previously noticed in a slight degree, became aggravated, and continued. At my visit the hæmorrhage was not great; there were no urgent symptoms, and I trusted that the *effect* of alarm might pass away with the cause which had occasioned it, with rest of body and quietness of mind. The principles to be acted upon here were to soothe and quiet the nervous system, to keep the patient in a recumbent position on a horse-hair mattrass, to supply light and unstimulating nourishment, to preserve the several functions in their normal condition, and to afford such an amount of fresh air as should give the lungs an abundance of oxygen; and should avoid, on the one hand, the stimulation of accumulated caloric, and on the other, the depressing influence of a too rapid abstraction of temperature.

Finding, however, that hæmorrhage did not entirely subside, in a day or two I made a digital examination in order to satisfy myself that the case was not one of placenta prævia, and also to determine upon the probabilities of abortion, or the resumption of gestation. I found the os uteri patulous, its lips swollen and flaccid, but no part of the ovum was engaged within it, and the placenta was not attached over it. Believing that, under such circumstances, abortion was inevitable, I exhibited the secale cornutum, with the view of obtaining its sedative influence generally, and of provoking the uterine fibres to contraction, in order to effect the expulsion of the ovum. Finding, however, no result from this treatment, in a few days I again examined, but the parts remained in *statu quo*.

My patient was a young lady of highly nervous temperament, and under this constant drain the action of the heart had become exceedingly irritable. During this time cold milk was one of the great means of her support, and her appetite remained unimpaired, so that she took as much as was wished; the symptoms gradually moderated, and the bowels were kept regular, still hæmorrhage was never long absent, and the case became embarrassing, from its protraction, and from the impossibility of adopting any decisive measures for terminating utero-gestation. Next there came the appearance of a blighted ovum, or as nurses call it, a false conception—membranes containing fluid—but no fœtus. Pain attended the expulsion of this body, and ceased directly afterwards, but there was no diminution, or gradual cessation of hæmorrhagic action, and no sensible change of the intra-uterine relations. In this way my patient went on, with a certain degree of improvement, and occasional attacks of uterine spasm, until the 4th of May, when I was summoned at four A.M with an urgent message that I would go over and see her directly, as she was "so very ill." On my arrival at her house, five miles from Farnham, I found that the account had not been exaggerated. The bleeding during the night had been terrific, and now her pulse was not to be counted. She complained of inextinguishable thirst, yet everything she swallowed was instantly rejected by vomiting; she was restless in the extreme, tossing about the bed, and retching continually. Hæmorrhage still continued, notwithstanding her *faintness*. Her countenance was white as the sheet, and her delicate hands were shrunk, and bloodless. The only encouraging circumstance she had about her was pain, but this only added to *her* sense of despondency, and to her conviction that she was dying—a conviction almost participated by myself; nevertheless hope—inextinguishable hope, clung to the manifest pain as to a sheet-anchor, I gave her at once sixty drops of Battley's sedative, with the immediate effect of quieting the sickness, allaying the jactitation, and enabling me to get nourishment and stimuli into the stomach. The actual loss, too, moderated from this time, pain went on, the os uteri became dilated, the membranes gave way, and in a couple of hours a six months' fœtus was expelled—still-born, but not having been long dead—the placenta followed shortly. From this time my patient rallied, and in three more hours I was able to leave her, with the comfortable hope that she was safely landed from the present emergency, and that she would recover: in fact her restoration was more rapid than could well have been expected; and although at first she could scarcely raise her head without fainting, and the action of the heart continued feeble, and excessively irritable, yet by great attention and good nursing she was able in a few weeks to leave her home for Ramsgate.

Now, it will be remarked, that in the conduct of this case, no mention is made of plugging the vagina, or of the application of cold vinegar and water; the former was not employed, because there was yet a lingering

hope, that utero gestation might be continued, if that organ were not provoked into uterine contraction—a hope which in all probability, plugging the vagina would have destroyed; and the latter was equally eschewed, because I more than doubt the efficacy of the continual application of cold. I have before me the memorandum of a case of uterine hæmorrhage, which occurred recently in London, in which the patient was subjected during a whole day, to the almost continuous application of a stream of cold water falling upon the pubes, *and she died*. Now, I am not at all suggesting, that she died *because* of the treatment; but submit that the depressing influence of cold and wet continuously, has a tendency to augment the exhaustion already occasioned by the hæmorrhage, and so to extinguish the last remnants of vitality. So in the case above narrated, my conviction is, that if the influence of this cold vinegar and water had been added to the already disastrous effects of hæmorrhage, the power of rallying would have been lost, and the patient would have sunk irretrievably. As it was, the case was with difficulty snatched from the jaws of death; her exhaustion was awful, and it was a fearful question, whether she could live another half hour; and if the powerfully sedative influence of cold, had been added to the other exhausting causes, my firm belief is that the scale, thus trembling in its balance, would have turned against the patient. The stimulating influence of heat is to be avoided unquestionably, so long as hæmorrhagic action with abundant power is going on; but my experience has repeatedly shown, that *this stage passed*, and the depressing influence of the loss of blood having been established, the hæmorrhage is much more readily controlled by the stimulus of *hot napkins*, and of a mustard poultice applied to the hypogastric region, or the scrobiculis cordis, than it is by the *continued agency of cold*. Above all, it is under these circumstances, that opium is the great sheet-anchor of hope,—*the remedy*, which, by soothing the nervous system, and congesting the cerebral vessels, enables the constitution to continue the struggle, supports the *vis vitæ*, and finally lands the patient in safety.

Let it be recollected, that the effects of the *long continued* application of cold and wet, are—first, to deprive the capillary vessels of their blood, to diminish their power of generating caloric, to make the patient wretched and miserable by lying in a pool of cold and wet, to exhaust her nervous sensibility, to depress greatly the powers of life and the consequent efforts of the *vis conservatrix*, and to lead the attendant practitioner astray, as to the amount of hæmorrhage, as well as to the quantity of red particles remaining in the circulating system.

If the blood be driven from the skin, where is it so driven, but to the large uterine veins? If shivering, goose skin, and a feeling of indescribable wretchedness from cold be produced, what compensating agency is set up for all this diminution of vital power? If coldness of the extremities be substituted for a genial warmth, and the blood and nervous excitability be both accumulated about the disturbed organ, what good is the result? If, as is the fact, sickness and jactitation, and consequently more rapid exhaustion take place, what good is gained—or rather, what rallying points are not voluntarily given up to the destroying agent? It is not a question whether the sudden and temporary application may not be useful, but whether its long-continued agency be desirable. If cold be applied, it is more useful in the earlier stages of uterine hæmorrhage, then to be employed in the shape of a piece of ice introduced into the vagina, or failing ice, a cold lavement at a very low temperature, to be injected into the rectum, may be had recourse to with advantage. If ice be employed, it should not be allowed to remain long in the vagina, or the life of the surrounding tissues may be destroyed. In either case there is a good principle before us, viz., to produce a coagulum, upon the mouths of the bleeding vessels, and so at the least, to gain time for ourselves and our patient.

It is obvious that in these cases of threatened abortion the bleeding proceeds from a partial separation of the placental vessels, and our object should be, not to drive as much blood as we can, through them, but to favour the formation of a clot upon their bleeding mouths, and thus to husband the strength and the resources of the patient.

The question will perhaps be asked,—Why, in the above described case, transfusion was not employed, as the most obvious and direct means of restoring the loss sustained by the patient. The most obvious reply in the instance just recorded, is, that one does not find oneself provided all at once, five miles from home, with the means of effecting transfusion. But on the general principle, *as applicable to all such cases*, I do not recommend transfusion, because we have not a sufficient number of cases of success on record;—because there is no proof that these cases as recorded, would not have done well without transfusion, if judiciously treated;—because there are dangers consequent upon transfusion, such as inflammation of the vein, the entrance of air into the veins, the uncertainty as to the quantity required;—and because, in the course of forty years practice, I have never known but one case of uterine hæmorrhage, which did not do well, without transfusion;—and that one was a case of placenta prævia, in which the loss sustained in a most attenuated form, was so great before I saw the patient, that she died almost before the birth of the fœtus.

In the course of my life I have witnessed a great number of cases of uterine hæmorrhage; some which have been treated with the application of vinegar and water, or napkins soaked in that fluid, and others without the application of cold at all, beyond what is necessary to keep the patient from being over-heated; and the result is undeniably in favour of the latter plan of treatment. The cold lavement, if exhibited in the shape of a quarter of a pint of ice-cold water, with from forty to sixty minims of tincture of opium, will be found to produce a very beneficial effect in allaying the morbid action, and especially in diminishing uterine spasm. Be it always remembered that peace of mind and the influence of peacefulness and hope should ever be borne upon the *patient's morale*; and such is the reciprocal

influence of body and mind, that this object will be more readily gained when the brain is supported by opium. Independently of medicinal agency, whatever may be the practitioner's own apprehensions—however exhausting to his own powers, when he finds the patient's life trembling in his hands, as a gossamer web, which the next moment may destroy, he is on no account to exhibit his fears, but to remain calm and unmoved, and so to inspire the patient with a confidence to which he is himself a stranger, but which in her own case may prove the very straw which will sustain life's ebbing powers, and save it from extinction. And thus will he obtain the inappreciable reward of being told by his patient—perhaps a young and interesting mother of a family—"Nothing saved my life but my reliance on your cheerful countenance." And is not the practitioner amply repaid for hours of agony by such a reward? To have saved a life by controlling his own feelings! He that conquereth himself obtains a greater victory than he that taketh a city.

Much has lately been written about the advantage of a small hand to an obstetrician, and I relate the following case to exemplify what has oftentimes occurred in my own practice. Many—many times have I been called in *to turn*, because the attendant parties had failed, and they had determined to avail themselves of the advantage of "Newnham's small hand."

On the 8th instant I was called upon by a very intelligent and valuable neighbour, to ask my advice on a case in which the placenta was retained in utero, but he could not tell whether it was adherent or not, because there was such an amount of spasmodic contraction of the os uteri, that after many efforts he could not succeed in introducing his hand. The fœtus had been born at six A.M., and it was now two P.M. I suggested giving the patient a full dose of opium, and when she had decidedly become under its influence, to try again the required manipulation. I then promised to call at five in the afternoon, which I did, and found him still in the same difficulty, with the impossibility of getting his hand into the uterus. Happily the hæmorrhage had not been great. At his request to try, if I could succeed better, I introduced my hand, without much difficulty, and found the placenta almost universally, and very intimately adherent. The very reason why there had not been more hæmorrhage, was because the placental vessels had not been partially detached. I could not, with any reasonable effort, succeed in detaching the placenta entire from the uterine parietes, and I was compelled to be contented with successively removing by far the larger portion, (though piecemeal,) in proportion as I could separate its adhesions, the remaining portion was then left to the care of nature, and up to this time (June 25th) she has not had a bad symptom, and is down stairs and attending to her household matters. The case needs no comment; one such fact is sufficient to show, that there is a great and decided advantage in the gift of a small hand.*

June 27, 1851.

* This patient's recovery has been *perfect*.—Sept. 12th, 1851.

Provincial Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 17, 1851.

THERE can be no hesitation now, on the part of the profession, as to what its conduct should be towards those recreant members who have deserted the paths of scientific medicine for the crooked bye-ways of fashionable quackery. Henceforth, our watchword must be—"Those who are not for us are against us;" and they must with one consent be treated with the ignominy which is the just due of traitors. Some time may elapse before the effects of the late grand demonstration, which has made our nineteenth Anniversary memorable beyond all precedent, shall be fully developed, but we feel as confident as we can do of anything yet in the womb of time, that those who come after us, will have reason to point to the Provincial Medical and Surgical Association as the engine which will have mainly contributed to disperse the Stygian emanations which now cloud the medical horizon. Quackery must from this time stand alone revealed in all its native deformity; its defects can no longer be hidden under the garb of legitimate practice.

We can well conceive that the proceedings at Brighton have created no slight sensation, not only in the hostile camp itself, but also amid those double-dealing individuals, who are playing the difficult game of keeping in with honest practitioners, while they are at the same time secretly abetting the homœopathic impostures. For the consternation of such we have no pity; whether they be found in the precincts of Royalty or in the humbler sphere of union practice, we would urge their expulsion from our ranks, as a foul blot on the honour of the Association.

It would be premature to discuss the probable decision of the Committee appointed to consider the conduct of the Association in reference to any of its members, who may directly or indirectly countenance irregular practice, but the names of the gentlemen so appointed may be taken as a guarantee that a measure of so much importance to the honour of the profession will be carried out with judgment, but at the same time with unflinching integrity. Membership of this great Association will be made a warrant for professional probity. We most earnestly

hope that the Colleges of Physicians and Surgeons will not think it derogatory to follow where they might—had they so willed—have led; and that the public may not much longer be misled by finding the names of the infinitesimal and other impostors upon the printed lists of those influential corporations.

We had on a former occasion to complain that the good intentions of the Admiralty Board, were often defeated through the insolent vulgarity of the Captains of our ships of war; we see, however, that this is not very likely to occur in future, as the Lords have taken the matter into their own hands, and have personally superintended the disposal of suitable accommodation to the medical officer. We read in the *United Service Journal* the following announcement:—

"We have the pleasure of recording the fact that during the visit of the Board of Admiralty to Devonport, their Lordships went on board the *Virago* sloop of war, and themselves selected a cabin for the Assistant-Surgeon. The Captain has given up his steward's berth, which is turned into an office, and the office and dispensary have been given to the Assistant-Surgeon, so that he has now one of the best cabins in the ship. This is proper feeling on all sides, and we trust the good example set by their lordships will be sufficiently indicative to all "Pig-whiffins" of what is expected of them, by those they are bound "to obey."

Our contemporary deserves the thanks of the Naval Assistant-Surgeons, for the zeal he has displayed in their cause.

We have received the following letter from Dr. Dillon, of Bath, by which it appears that we were wrong in supposing that Dr. Davies' signature was attached to the review of Dr. Tunstall, to which we alluded in our last number. There was an interval of several months between the receipt of the MS. and its publication, which will easily account for the mistake. This, however, is now happily rectified, and we trust that all unpleasant feeling on the matter will be committed to oblivion.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—Your article of the 3rd instant, referring to the review of Dr. Tunstall's book upon the Bath waters, which appeared in your journal last year, has just attracted my notice, and I hasten to set you right on the subject of authorship, respecting which I perceive that you have accidentally fallen into error.

I wrote that review, stating therein, impartially, what I thought of the book, without intending any favour whatever to the author; and I am glad to find that the estimate I formed of its merits has been justified by the favourable notices of other and more competent reviewers.

It was far from my intention to say on that occasion anything to offend the medical practitioners of Bath, amongst whom I believe there are as disinterested and as honourable men as any in the profession; and I was really astonished when I heard that some of them made an outcry at a simple statement of facts, about which no one who knows Bath as it is, and recollects what it was, entertains any doubt.

I am responsible for that review: no one else knew anything about it; and although I have never, willingly, obtruded my name on the profession, you are at liberty to use it, on the present occasion, for the satisfaction of the members of the Association.

The private letter, which I addressed to you with the review, bore my own name and address, in my own handwriting, *and no other name or address.*

I have the honour to be, Gentlemen,
Your very obedient Servant,
GARRETT DILLON, M.D.

Bath, September 5, 1851.

Reviews.

On Gout; its History, its Causes, and its Cure. By Wm. Gairdner, M.D. Second Edition. London: John Churchill.

Among the works put forth by the medical press with a view to represent the sciences we cultivate and profess in the language of progress, not least conspicuous is the new edition of Dr. Gairdner's book on "Gout;" indeed, if we are not greatly mistaken, the eighth Chapter of this fresh issue would do credit to names as conspicuous and trustworthy in chemical, as that of the author is in medical, science. The experienced, nay, almost the young practitioner, grows weary of those mere portraitures of disease which he can sketch for his own use with much greater profit than he can read off from authors' pen; so weary, indeed, as time advances, we find, in spite of the pretensions of our would-be instructors, that there is less and less that we can force ourselves to read. It is not the thirst for knowledge that declines, but a scarcity of aliment that prevails; and inductive minds thus prefer their own observations and thoughts to the empty pretensions and stale rehearsals of self-eulogising writers.

Talent enjoys perpetual youth, and, whatever may be the standing of its owner, shows the

same freshness as at first in its undertakings. Dr. Gairdner, with an energy which would have done him credit in earlier years, has entered on the great field of modern research, and the only one which for some time to come can yield a physiological harvest—the respiratory process. In treating of gout, of its dyspepsiæ on the one part, its newly compounded secretions on the other, he sees clearly that the point at which to observe is in the lungs; that the object of research is to determine the healthy processes effected in the blood during its circulation in an atmosphere of oxygen and nitrogen—processes on which our knowledge is in its infancy, yet which, little as it is, already throws light upon the nature of secretion in health and disease also.

The author has plainly and effectually opposed Liebig's artificial theory of respiration. He shows on what slight foundation the opinion is based which invests the iron of the blood with the mere office of carrying oxygen, and clearly points out the true mode of its absorption and distribution. The function of respiration, according to Dr. Gairdner's view, which is made to rest on the most admirable experiments, instead of being one of defecation only, is one of production—of blood-growth—embracing a combination of uses of great interest to physiology, no less than the building up of organic principles, fibrin, gelatin, and others, while heat is generated by its decarbonising processes.

In our notice of the first edition of this book, we drew attention to the author's experiments and pathological views, (which have since met with a satisfactory confirmation by Lehman,) showing *the vicarious nature of urea and uric acid in the renal secretion.* In elucidation of this subject, so intimately associated with pathology, we can do no better in a second notice than advert to the new physiological researches put forward in this edition.

"Deeply interesting in the history of gout," says Dr. Gairdner, "is a study of the physical and chemical constitution of the blood. From all that has been written in preceding chapters, it must be apparent that the influence exercised by the oxygenation of the blood over the stable and well-balanced phenomena of health, is hardly more striking than the same process in the fluctuating symptoms of disease. It becomes, then, of vast importance to the pathologist, as well as to the physiologist, to determine, with clearness and accuracy, in what this process consist."

Regretting that practising physicians, whom he justly considers the best qualified for the investigation, have avoided the difficulties of the subject, the author proposes to confine himself to that portion of it which has an immediate bearing on practice.

"The experiments of Magnus have satisfactorily established the facts, that oxygen, carbonic acid, and nitrogen, do all exist in both arterial and venous blood; that oxygen is found in much larger proportion in arterial than in venous blood; and that a great increase of carbonic acid takes place in venous blood. It is certain, therefore, that the oxygen must, in the capillaries, deprive either the tissues themselves, or the mass of circulating blood, of a portion of their carbon, to form the new compound. *But this is not enough to account for the oxygen, which disappears in the process of respiration.* The concurring testimony of nearly all chemists prove that a larger amount of oxygen is absorbed by, than what again issues from, the lungs in respiration in the form of carbonic acid gas."

Passing over a disquisition on Liebig's opinion respecting the destiny of this superabundant oxygen, and other matters of opinion relating to it, we will proceed at once to the practical business of the composition of albumen and fibrin, in quoting the author's own words:—

"Remembering the advice given by Mulder, it appeared to me far more hopeful to make a study of the process which nature herself employs in accomplishing her own ends. I looked, as I have said, to the circulation as the field in which to expect results. I remembered that both the great ingredients of the atmosphere disappeared during respiration in a manner yet unaccounted for. I remembered, also, the experiment of Mylne Edwards, on the disappearance of nitrogen, now strangely neglected. I felt assured that here I should find a solution of all my difficulties.

"It was natural to expect, that if the albumen of the blood did, during respiration, pass into fibrin, a difference in the amount of fibrin in arterial and venous blood would be found. This had already been satisfactorily proved by Berthold Mayer, Denis, and Müller, but none of them seem to have arrived at the right conclusion. They attributed, as was very natural, the greater amount of fibrin in arterial blood to the fact that it had received the contents of the thoracic duct from the food, while the venous blood had already parted with its fibrin in the course of the systemic circulation. The multiplied testimony, however, of all these authors, as to the different condition of the fibrin in arterial and venous blood, convinced me that there was another explanation to be given than this."

"The fibrin of arterial blood is described by all observers as constituting thick, solid, shining bundles, while that of venous blood is soft and dilute. *This difference is ascribed by them to the fibrin in venous blood being in a state of greater division, and not to that of arterial blood having been more highly elaborated in respiration.*"

"The buffy coat of inflammatory blood is universally allowed to be fibrinous, and it is certain that it always indicates a considerable increase of fibrin in the blood. Though both respiration and circulation are hurried in inflammatory fevers, yet it is quite conceivable that the phenomenon we are considering, as well as the firm coriaceous coagulum always met with in such cases, might not be owing to increased generation, but to arrested deposit of fibrin, caused by great disturbance of the system. The explanation, however, must necessarily be abandoned, since the discovery by Andral and Gavarret, that in adynamic and putrid fevers the very opposite state of things takes place. The soft, pultaceous, extended coagulum presented in these cases, is indeed familiar to all physicians."

Mulder conjectured that fibrin had its origin in respiration. He says the bioxide and trioxide of protein are produced during respiration, and are found in the blood as healthy constituents, being generated by the oxydation of the substance which, during the coagulation of the blood, is changed into fibrin. Simon also expresses very clearly the opinion that fibrin takes its origin during respiration; but neither of these authors have pursued this important subject, and removed it from the field of conjecture. Dr. Gairdner has the merit of having settled this important point by experiment. He says:—

"It became, therefore, a matter of much interest and considerable thought, to contrive an experiment which should make evident the truth I desired to elicit. At first it appeared to me probable if albumen passed into fibrin by the aid of, and during the process of, respiration, that blood abstracted before and after sharp exercise would give traces of the fact. This experiment proved to be a total failure of the proposed object, yet was not unproductive of interesting results. At first it seemed that the desired truth was disclosed, *for the bulk of the fibrin was very remarkably increased after exercise.* The blood was drawn from the jugular vein of a horse, which was afterwards smartly galloped for an hour, and again bled from the same incision while still reeking with exercise, but the fibrin, which, during the agitation of the animal, had undergone a remarkable increase of bulk, proved on drying not to have acquired any addition of weight. It had not suffered any change."

The author, on reflection, said that if the increase of fibrin taking place on the arterial side did not return to its ordinary standard in the veins, fever must be engendered; and moreover, that any such fibrin created must be instantly wanted to replace that which was lost to the substance of the muscles. He was satisfied that oxygen was, if not the sole, the principal, agent in the production of fibrin. Blood was then taken from two rabbits, one of which had been made to breathe an atmosphere highly oxygenated, with the following result:—

"The blood of the rabbit in the natural state contained 1.55 of fibrin, while that which had breathed the oxygen for half an hour contained 2.9 of fibrin in 1000 parts."

To obviate the fallacy which various constitutions and varying health imposed, experiments were multiplied, the blood being taken immediately from the aorta of the rabbit.

"My first care was to establish a standard of health in the animal selected. None was so convenient as the rabbit; six males, in apparent perfect health, were selected, and the blood taken as above stated, examined with a view to establish the quantitative proportion of the different organized principles, with the following result:—

"The following analyses were made to determine the relative proportion of the organic constituents in 1000 parts of the blood in the rabbit:—

	Fibrin.	Globules.	Albumen.
1	1.8	88.	40.6
2	1.45	77.14	37.2
3	1.45	95.5	40.
4	1.5	70.	52.
5	2.	92.	50.
6	1.73	71.5	58.
Average	1.65	82.35	46.3

"I next sought to determine the changes which oxygenation of the same quantity of blood would induce, with the following result:—

	Albumen.	Globules.	Fibrin.
1	40.	75.	2.5
2	45.7	73.2	2.4
3	35.	60.5	2.3
Average	40.23	69.56	2.4

"An inspection of these tables," continues Dr. Gairdner, "is sufficient, I think, to establish, as a principle, that oxygenation and fibrination are identical."

The pages devoted to gelatine, from which we have not room to quote, are among the most able and suggestive in the volume; and we feel assured that no chemical observer can peruse

them without acknowledging their singular importance.

We have preferred the consideration of these scientific results, forming the first portion of the eighth Chapter, to quoting the valuable materials contained in other portions of the work, as discoveries of this class, the fruit of long-continued labour and thought, demand to be brought prominently before the profession. The application of these and other striking chemical researches, having reference to the urine in gout, find their due application in the body of this truly philosophical volume; and while on this subject we may call attention to a note on the theme of Cattle-feeding, which brings before the reader with great effect the absurd methods which our agriculturalists adopt in stall-feeding, and the folly of associations in offering prizes for faults not excellencies, disease not health.

The practical parts of the work are throughout developed and enriched, but our object being rather to put the practitioner in possession of the fact that a work, so able and novel, on the subject of gout, in its second edition, has reached us, than to give an analysis of its multifarious contents, we draw our notice to a close by remarking that Dr. Gairdner's work is one which few readers would be willing to find absent from their shelves.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

MAY 1st, 1851.

DR. FLETCHER IN THE CHAIR.

Scirrhous Mamma.—By DR. RUSSELL.

The specimen was given Dr. Russell by Dr. Mackay, who removed it by operation.

The tumour occupied the mammary gland; it was of considerable size, of pearly aspect, and firm consistence. The fibrous bands very distinct; in one part they formed strong laminæ, penetrating side by side to some depth into the tumour; they enclosed a softer matter, quite distinct, which projected from the surface in the manner of lobules of fat. An opaque fluid was expressed from the tumour; this fluid contained a large abundance of cells, delicate, irregularly rounded, with distinct double outline, and bright nucleus, in diameter from 1-1667th of an inch downwards; they manifested great disposition to cohere, scarcely a single one floated loose. There were, besides, large cells loaded with fat globules. The fibrous lamina was composed of strong fibrous tissue, imperfectly fibrillated, becoming transparent by acetic acid; the firm adhesion of the cells to the fibrous stroma and to one another, increased the proportion of the solid frame work of the tumour; in parts the cells had a kind of imbricated arrangement, so as to form kinds of bands or ridges. Dr. Mackay gave the following history of the case:—Mrs. S., aged 45, thin, not healthy looking, the mother of several children; she always menstruated naturally. She perceived a small lump in the left mamma eight months ago; it increased steadily and latterly, was the seat of lancinating or darting pains; it was moveable immediately under the nipple, which was unaffected and seated over the centre. I removed the tumour by excision.

Ulceration of the Cartilages of the Ankle; Caries of the Tibia.—By W. C. FREER.

THE subject was a boy, aged 16; he had been suffering from caries of the tibia for ten months, but under rest and care, he was slowly recovering; his parents, however, being impatient of the tardy progress effected, placed him under the care of a quack, who immediately ordered away the crutches, and desired the patient to use the limb; inflammation of the ankle set in, but the treatment was nevertheless continued; irritative fever arose, and in a fortnight, Mr. Freer removed the limb.

The shaft of the tibia was in progress of recovery from the carious state by the formation of new bone; the ankle cartilages were ulcerated, and tawny gelatinous lymph was deposited within the joint.

JUNE 5TH, 1851.

W. PARTRIDGE, ESQ., IN THE CHAIR.

Retained Menstrual Fluid.—By Drs. ELKINGTON and RUSSELL.

The fluid was retained in consequence of an imperforate state of the hymen; and the remarkable part of the case is, that the patient was a married woman, and had had connexion repeatedly. The obstructing membrane was perforated by Dr. Elkington, with complete relief.

The fluid was of a chocolate colour, of the consistence of treacle; it required some shaking to mix it with water. Under the microscope it consisted of cells, of various sizes; by far the largest proportion bore considerable affinity to blood discs; they were of average diameter 1-2500th of an inch, more or less directly circular, some containing a bright nucleus, others a large granular nucleus, and some even a nucleolus; their outline sharp and defined; double outline distinct in very many. Many were of smaller size than those described, and of more irregular figure. There were, besides, a considerable number of cells much larger, the largest 1-1000 of an inch diameter, but few attained that size; these were more opaque, finely granular, deeper coloured than the small ones. Some of them seemed splitting up towards the centres. They contained a considerable nucleus, some two or three. The cells were of a bloody tinge, the larger ones very decidedly so; the small ones less deep in colour, though more deeply tinged than blood-globules generally are. Around the cells was a quantity of transparent matter, apparently debris, scattered over the field. There were, besides, several nucleated epithe-

lial cells, doubtless from the passages, some of them exactly like those common in urine. The cells were not influenced by water. On adding acetic acid to the fluid, either pure, or mixed in water, the cells all collected themselves into dense groups, and became more transparent, and their structure less distinct. When the fluid was mixed with water, no coagulum was produced, either by heat nor by nitric acid.

The general microscopic characters of the fluid indicated great affinity to those of blood-globules, but the large and deeply-coloured cells described were quite distinct from any appearance ever presented in blood. It cannot, however, be asserted that these cells would exist in the healthy fluid, as the microscopic character of the fluid might have been affected by its long confinement in the passages. The chemical test established the absence of albumen.

Foreign Department.

On Tracheotomy in Œdema Glottidis.

M. Séstier (*Archives Générales*) has contributed a paper urging the earlier and more frequent resort to this operation in suitable cases. He gives an analysis of 138 cases of œdema glottidis, in thirty-six of which the operation was performed, with the result of preserving life in thirteen, and materially prolonging it in eight. He has also ascertained that the success of the operation very much depends upon the previous healthy state of the larynx, and recommends it chiefly in such cases, but does not consider it contra-indicated where prior disease has been known to exist, unless it be of an advanced stage and incurable character.

As regards the time of performing the operation, M. Sestier would not be precipitate, as in several apparently very severe cases the disease has been got under by vigorous treatment. But, on the other hand, he counsels against waiting until no other chance is evident. He is guided by the amount of suffocative dyspnœa, together with feebleness of respiratory murmur.

With reference to the operation itself, the author gives the preference to crico-trachetomy. It is easier than tracheotomy, and less likely to be followed by the entrance of air into the veins, or of blood into the trachea.

Retention of the Menses; Rupture of the Fallopian Tube; Death.

A case of this nature is reported by Dr. Marchand (*Archives Générales*, Juillet). The subject was a young woman, aged 22, who had retention of the menses from imperforate hymen. This impediment being discovered a crucial incision was made, and several pints of a dark inodorous fluid escaped. She was making a good recovery when she was suddenly seized with peritonitis, from which she died.

On inspection after death the uterus was observed to be larger than natural, and the os uteri widely dilated. The peritoneum was universally inflamed, and in the left iliac region it was found that menstrual fluid had escaped from a largely-distended and convoluted fallopian tube. This, in the author's opinion, was the exciting cause of the fatal symptoms.

It may be stated that this is mentioned by M. Bernutz as one of the accidents attendant upon retention of the menstrual secretion.

Two Cases of Supposed Internal Strangulation; Recovery after the exhibition of Olive Oil.

M. Delotz (*Revue Medico-Chirurgicale*, Juillet) communicates two cases of intestinal obstruction, in both of which stercoraceous vomiting had ensued. In the first case the patient appeared in an absolutely hopeless condition, when the author induced him to swallow two pints of olive oil in two successive draughts. To his great surprise the bowels acted a few hours after, and the man recovered.

The second case was apparently one of simple constipation, not depending on mechanical obstruction.

Results of Various Modes of Treatment in Pneumonia.

Dr. Dietl, an Austrian physician, who appears to have been very undecided in his therapeutical principles, has recorded the results of his practice in pneumonia. At one time he was a great advocate for bleeding and the antiphlogistic system, subsequently he turned homœopath, and still later he trusted to tartar emetic. Being dissatisfied with the mortality under each of these plans, he determined to abide by the *methode expectante*, or do-nothing system, and he declares that the recoveries have been more numerous than when he treated his patients medicinally. He gives the following statistics, which are so far valuable, inasmuch as they show that homœopathy and doing nothing are convertible terms :—

Of 360 cases of pneumonia, 85 were treated by bleeding, with 17 deaths, or 20 per cent.

Of 106 healed by tartar emetic, without bleeding, 22 died.

Of 189 treated by a purely expectant method, 14 only died.

The mortality under homœopathic treatment was the same as when no medicine at all was given.

Is the appearance of Albumen in the Urine a Favourable Sign in Diabetes?

M. Rayer makes this question the subject of some practical remarks in a paper read before the Biological Society of Paris. He alluded especially to a case which he saw in consultation with M. Landouzy, which had improved, to a certain extent, under the use of alkalies, with abstinence from farinaceous matters, when albumen was detected in the urine. There were, however, no other signs of Bright's disease; and the appearance of albumen was a phenomenon for which M. Rayer had no ready explanation.

MM. Dupuytren and Thenaud considered that when albumen appeared in the urine of a diabetic patient it was indicative of improvement, being, as it were, a

transition stage between the saccharine state and that of health. M. Rayer, however, is disposed to regard the change as not salutary, as in cases witnessed by him, though the sugar disappeared, the occurrence of œdema showed that the change was not for the better. In fact, in more than one case, although there was no recurrence of sugar, the patient died of one or other of the consequences of albuminuria.

A case related by Dr. Christison also proves that the appearance of albumen in the urine may be an indication of a serious complication, to be followed soon by other symptoms of renal disorganization. The case was that of a man aged 40, who had been the subject of diabetes for two years. Unexpectedly it was found that the urine coagulated by heat and nitric acid, and that its specific gravity became lower, until at length it was as low as 1,010, without any traces of sugar being present. The man soon after died from diarrhœa, and after death his kidneys were found in an advanced stage of granulation. It may, therefore, be taken as a pathological fact that though in some cases the substitutions of albumen for sugar in the urine of diabetics may be a good sign, in others it may indicate a serious complication.

Physiological Experiments on the Bodies of Executed Criminals.—By M. Duval.

M. Duval, from his position as teacher of anatomy at Brest, enjoys frequent opportunities of examining the bodies of culprits executed by the guillotine. The theatre of anatomy is so near the platform that the bodies are received within five minutes of decapitation. Among the facts which he has ascertained are many which bear upon points in physiology, still *sub judice*. The following are the results of the first examination recorded in the *Gazette Médicale*, Juillet 12th :—

A man was decapitated for murder, and the corpse was brought to the table in less than five minutes. The first thing which attracted notice was that the divided extremities of the carotid arteries were projected in successive jerks, at the same time ejecting small quantities of blood. The jugular veins bled continuously.

No reflex action could be induced by any pinching, or other mechanical irritation.

After devoting a quarter of an hour to the opening of the abdomen, the chest was laid open, and the heart was seen beating with great distinctness ; the left auricle, in particular, exhibited strong and perfectly regular action forty-four times in the minute, and continued to do so for an hour.

Before the chest was opened galvanism was applied to the spinal marrow, and immediately caused movements of expiration and inspiration, accompanied by a hoarse noise in the larynx. After opening the chest galvanism was applied to the intercostal muscles, and caused the ribs to approach each other in a notable manner. The stomach was full of food ; but none escaped after its removal, in consequence of the rigid contraction of the cardiac and pyloric orifices. The bile was dark green, and of a gummy consistence. The spleen was empty and wrinkled, and could not be made to contract under galvanic action ; but the ureter contracted manifestly. The spermatic vesicles were filled with a liquid fluid, containing living spermatozoa.

In another case the pupils were contracted by galvanizing the third pair of nerves in the cranium.

Case of Traumatic Tetanus; Sulphate of Quinine in Large Doses; Cure.

A boy, aged 16, was admitted on the 1st of December, having a slight wound on one of his toes, produced by the fall of a keg of water which he was carrying on his head. The wound was dressed with cerate. Several days afterwards tetanus appeared, and followed its ordinary course of—first, trismus, then convulsive movements of the face and neck. An active depletive treatment was immediately adopted, without any amelioration. At this time M. Foucard, de Pont Ste.-Maxence, had published the successful result of the use of large doses of quinine in similar cases. This remedy was ordered to be given to the exclusion of every other. It was first administered to the patient on the 15th of December, in daily doses of fifteen grains, with small quantities of morphia. On the next day an improvement in the symptoms was observed. The dose was increased to fifty grains in a few days, and was again gradually reduced. The patient quitted the hospital, cured, on the 12th of January.

The grounds of the administration of this remedy are apparently empirical, but this is the case with many other valuable remedies. The researches, however, of Andral and Monneret go to show that large doses of quinine exert a beneficial influence on rheumatism, by diminishing the portion of fibrin of the blood. It is, therefore, logical to infer that in tetanus a sedative action is exerted on the muscles. In the case now related the only ill effects produced by the large quantities of quinine were slight impairment of vision for a short time, and some degree of tinnitus aurium.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

Uses of the Pancreatic Fluid.—By Dr. Bence Jones.

Our readers will recollect a memoir by Dr. Bernard, translated by us in this journal, in which the author believes he has established the fact, that the office of the pancreatic secretion is to saponify fatty matters. Dr. Bence Jones expresses himself as not satisfied with this explanation, but considers from other experiments performed by Dr. Lenz, that this fluid has no such power. His remarks are as follows :—

That the pancreatic fluid is not necessary to enable fatty substances to be absorbed, has been shown thus by Frerichs and Lenz. After they tied the pancreatic duct in cats, they were given no food for from twelve to twenty-four hours, so that all the pancreatic juice which was in the intestine might have passed out of it. Food,

consisting of milk, fat, flesh, or butter, was then given; and, after some hours, usually from four to eight, the animals were killed; and they found, over and over again, that the lacteals and the thoracic duct were full of milky chyle. Frerichs put a ligature round the small intestines of animals (who had eaten nothing for some time) much below the opening of the bile and pancreatic ducts; he then injected milk, or olive oil, or an emulsion of albumen and oil, into the intestine below the ligature, and, after two or three hours, he found the lacteals quite full of milky chyle. Experiments are detailed, in which butter was given in quantity to cats, but not one trace of the volatile acids of butter could be found in the bowels, in the chyle, blood, or bile. Frerichs also found that other animal fluids, like the pancreatic juice, as soon as they began to undergo decomposition, effected as much change of fatty matter into fatty acid and glycerine as the pancreatic fluid did. He also states that the pancreatic juice, setting aside its chemical action, does not make a better emulsion,—that it does not divide the fat or oil better than other animal fluids. He found that when acidulated with hydrochloric acid, it had no action whatever on fat or on albumen,—that it had no power to act as a solvent of the albuminous part of our food. He states that its uses are to change the starch into sugar, and to promote the secretion of the bile; that, with the aid of the bile and the intestinal fluid, it effects, though it does not solely effect, a fine division of the neutral fat which is fluid at the temperature of the body; but, further than this, he says there is no peculiar specific action of the pancreatic juice. The pancreas seems rather to be a supplementary gland to the salivary glands intended to insure a full change of all the starch taken into the stomach. At present I cannot admit that its action on fatty substances in digestion is proved.—*Medical Times*, May 31.

PRACTICAL MEDICINE AND PATHOLOGY.

On the Administration of Cod-Liver Oil.

We extract from the *Gazette Mèdicale de Lyons* the following modes of exhibiting this nauseous remedy:—

1. Cod-liver oil, 30 grammes; solution of carbonate of potash, 8 grammes; syrup of orange peel, 30 grammes. Mix; a teaspoonful or two twice a day.

2. Cod-liver oil, syrup of orange peel, aniseed water, equal parts. Mix; a tablespoonful for a dose.

3. Cod-liver oil, 250 grammes; gum arabic, 30 grammes. Make an emulsion, and add syrup of orange peel, syrup of peppermint, utrq 30 grammes, A large table spoonful for a dose.

The disagreeable flavor of the oil may be disguised by hot milk or coffee.—*Revue Medico-Chirurgicale*, Fev., 1851.

On Pus in the Urine; its Diagnostic Value in Diseases of the Genito-Urinary System.—By J. Hamilton, Surgeon to the Richmond Hospital.

The author observes that pus may appear in the urine under different aspects:—First, as an uniform deposit of a pale white colour, subsiding after micturition, but capable of being diffused by agitation. This is pure pus, in acid urine. Secondly, mixed with mucus in acid urine, presenting an uniform tenacious, slimy, yellowish-white deposit, showing under the microscope irregular pus discs. Thirdly, after being acted upon by the ammonia in decomposed urine, it appears as a thick ropy mucus, with some transparency beneath, and exhibiting a superstratum of yellow opaque pus.

Pure pus may get into the bladder from the bursting of a neighbouring abscess, as in the broad ligament in women, or the prostate gland in men, of which the author gives examples.

When pus is mixed with the urine from inflammation of the vesical mucous membrane, a very essential difference is observed. In these cases the urine enters the bladder from the kidneys, acid, and becomes mixed with the purulent and mucous secretions of the inflamed membrane. If these are not very abundant the urine remains acid, and is passed so, but on standing soon becomes decomposed, and ammonia is generated, which acts on the pus and converts it into a thick ropy mucus. It also combines with the phosphate of magnesia in the urine, and forms the triple phosphate, which either floats on the surface as an iridescent pellicle, or is fixed as prismatic crystals in the mucous deposit.

If, as in paraplegia from injured or diseased spine, the urine is long retained in the bladder, it undergoes certain changes, the deposit takes place in the bladder itself, and the decomposition of the urine next the deposit commences, while the superstratum remains acid. But when the inflammation becomes more intense, and the morbid secretions very abundant, the whole of the urine will become alkaline in the bladder. —*Dublin Quarterly Journal*, May, 1851.

SURGERY.

Treatment of Chordee.—By John Milton, M.R.C.S.

[Mr. Milton, after trying various antispasmodics, has come to the conclusion that none is equal to camphor, in decided doses. Speaking of the Spiritus Camphoræ, he says:—]

A teaspoonful is to be taken at night in water before going to bed, and *every time the patient wakes with the chordee let him at once rise and repeat the dose.* In the milder cases, one dose for a night or two is generally enough. In the more severe ones the symptom is generally removed at the end of the second night, becoming, in the meantime, milder and less frequent after each dose. So long as the clap remains bad, I frequently recommend the patient to take a teaspoonful at night, before going to bed, which suspends the chordee till the cure is completed. This plan of treatment also answers well in the bearing-down pains to which women are sometimes subject in clap; but as here, contrary to what it is in men, these pains are generally worst in the daytime, it is best to use the essence of camphor largely in the medicine they may happen to be taking. It must, however, be taken in

full doses. A violent sudden pain like that of chordee requires an equally powerful remedy, and there is no use in trifling with it. A less quantity than a teaspoonful will not always suffice to abate the pain at once, though it may materially alleviate it; just as a moderate dose of chloroform will lull the acute pain of an operation without rendering the patient insensible to what is going on, while a smaller quantity, in one full dose, produces complete torpor. Now, as a teaspoonful or two may be safely taken, it is best to insure success at once. In one or two cases it has produced some sickness, and strangely enough, this has been more the case with small doses than with large ones; this was probably caused by something having been previously taken that had in some measure disordered the stomach. At any rate the instances have been too few to make the affair of any moment. I only allude to it here that no one might, by its appearance, be discouraged from giving so valuable a remedy as camphor really is. It is best taken in water, as if dropped on sugar it produces a strong sensation of heat in the mouth.—*Medical Times*, July 19.

Encysted Tumour, containing Fæces.—By Dr. Macilvaine.

A curious case is reported of a negro, who complained of a tumour between the anus and point of the coccyx. It was supposed to be adipose sarcoma, and was submitted to operation for removal. The first incision laid open a cavity filled with fæces, which the operator proceeded to turn out. He then explored the cavity, with a view to discover the opening through which the fæcal matter had entered, but could detect no communication with the rectum. Satisfied that the cavity was a closed sac, the indication was plain, and it was dissected out. This was accomplished without any wound of the continuity of the sac, except a very small snip with the point of the scissors. It was lined with a membrane having very much the appearance of the inner lining of the turkey's gizzard. The wound was closed with sutures, and dressed with a compress. The cure was accomplished in a few weeks, principally by granulation. The fistula was operated on shortly after, and the patient discharged cured on the 26th of March.

The origin of this tumour the author supposes to have been as follows:—An ulcer having perforated the coats of the rectum, fæcal matter was forced out and impacted in the cellular tissue between the rectum and coccyx. Here, not giving rise to sufficient irritation to secure its discharge by ulceration, it became encysted. In the course of time the original ulcer cicatrized, thus closing the communication between the rectum and the sac. This view is confirmed by the existence of a distinct cicatrix at the upper part of the sac, at the point of its closest connection with the rectum.—*American Journal of Medical Science*, April, 1851.

MIDWIFERY.

The Cæsarean Operation in the Vienna Lying-in Hospital.—By Dr. Arneth.

In his summary of the obstetrical practice of the Vienna Hospital, Dr. Arneth states that the Cæsarean section was never performed, except in cases where the narrowness of the brim of the pelvis was believed to be so great, as to render it impossible to drag the imperforated child's head through it with safety to the mother. So strictly has this rule been kept, that out of somewhat upwards of 200,000 confinements that have occurred in the Lying-in Hospital of Vienna, between the years 1789 and 1851, the Cæsarean section has only five times been resorted to. All the five mothers died. The children survived the operation, and of some of them there were accounts some years afterwards. Professor Dubois has informed Dr. Arneth that he had performed the operation twelve times without having had any successful case; nor is he aware of any practitioner in Paris having been more fortunate. Professor Stoltz of Strasbourgh, lately informed him that he had operated four times out of six with good success; nay, in one case he was even fortunate enough to see a mother twice surviving this dreadful operation. Everywhere on the continent it is an established rule to perform Cæsarean section in every case of a mother dying pregnant in the seventh month or later. The essay of Bonchut, which has lately been crowned with the prize of the French Academy, proves that with the last pulsation of her heart the mother dies, and that, consequently, the operation of the Cæsarean section may be performed immediately afterwards. In four cases, children were saved by the operation in the Vienna Lying-in Hospital. Two of the mothers died of phthisis, one of eclampsia, one of gangrenous inflammation of the cellular tissue of the neck.—*Edinburgh Monthly Journal.*

BIOGRAPHICAL NOTICE OF THE LATE DR. JOHNSTONE, OF BIRMINGHAM.

The death of Dr. Edward Johnstone, which took place at Edgbaston Hall, on Thursday, the 4th inst., after an honourable and useful life, prolonged far beyond the Scriptural term of "threescore years and ten," calls for more than the passing notice which the local historian accords to the generality of such events. Commencing his professional career in Birmingham at a period when comparatively few of the most aged members of the community now living had entered upon their existence, he may be regarded as a connecting link between the present generation and one long since passed away. It was the good fortune of Dr. Johnstone to belong to a family which has added several names to the muster roll of men who, by their high character, attainments, and natural gifts, have adorned the practice as well as extended the boundaries of medical science. On settling here at the early age of twenty-three years, he accordingly enjoyed the advantages which might be expected to result from the possession of a name already associated with distinction in the path of life which he had himself selected, and he had also the additional benefit of the friendly countenance of the late Dr. Ash; but the young physician, it would appear, soon gave evidence that he possessed talents and industry which rendered

him altogether independent of such adventitious aids. In a comparatively few years his reputation was placed on a solid and lasting basis; and that increasing years but added to its lustre is conclusively attested by the fact that the completion of the fiftieth year of his practice was celebrated by a public dinner, which was attended by upwards of one hundred gentlemen, a large proportion of the assembly consisting of his medical brethren in Birmingham and the vicinity. Recurring for a moment to those who preceded him, we may observe that Dr. James Johnstone, his father, who greatly distinguished himself as a physician, first at Kidderminster, and afterwards at Worcester, in which places he carried on a large and successful practice for more than half a century, was the author of the discovery which led to the employment of the fumes of mineral acids for the prevention of infectious fevers, although the merit was many years afterwards claimed by Dr. Carmichael Smyth, whose pretensions were successful in obtaining from Parliament a grant of £5,000. The claims, however, of the real public benefactor in this matter have since been fully admitted by the profession and the public, mainly, no doubt, through the ability and filial zeal of his son, the late Dr. John Johnstone, of Birmingham. An elder brother of the subject of our present notice, Dr. James Johnstone, after graduating with great *éclat* at Edinburgh, was elected one of the physicians to the Infirmary, at Worcester, where the zeal and ability which distinguished him in the pursuit of scientific knowledge obtained for him a large share of practice at a very early period of life, which only extended to his thirtieth year. Having been called upon by the magistrates of the county to combat the gaol fever, which then prevailed, he engaged in the discharge of that important duty with an alacrity and self-sacrifice which rendered him a victim to the pestilence which he was eminently successful in checking. His premature death was recorded and lamented by the illustrious philanthropist John Howard. Dr. Edward Johnstone himself pursued his studies at Edinburgh, where, on the 14th of June, 1779, he obtained the degree of M.D., selecting "*De Febre Puerperali*" as the subject of his inaugural treatise, which on being published elicited the discriminating praise of the eminent French Surgeon M. de Ponteau. In the autumn of the same year, on the opening of the Birmingham General Hospital, he was elected, with Dr. Ash, Dr. Withering, and Dr. Smith, one of its first physicians, an early recognition of his professional abilities; and he is probably the only survivor of all those who had anything to do with the establishment of that institution. In the appointment which he held for a number of years, with honour to himself and benefit to the charity, he was succeeded by his brother, the late highly-esteemed Dr. John Johnstone. But the record of his services would be very incomplete, did we not mention that Dr. Johnstone was also a zealous promoter of the dispensary for supplying medical and surgical attendance to the sick-poor at their own homes. He was an active and munificent patron of every useful and charitable institution, and his able advice was at all times accessible at his own residence to the less affluent. The one in which, for more than twenty years of his later life he took the greatest interest, was the Medical School, now Queen's College. In the year 1824, when Mr. Sands Cox, the founder of the College, submitted to him the plan of the original institution, the doctor entered warmly into the scheme. He afterwards presided at the opening lecture, and was a constant attendant during its entire course. On the plans for the school being matured, he accepted the office of President, and for a period of eighteen years was never absent from the Council Board. When, in 1836, the doctor entered his 80th year, the Council deviated from its usual course, by fixing its anniversary meeting on his birthday, namely, the 26th of September. On the same occasion a large body of the students presented Dr. Johnstone with an address. In the year 1840 he presided at the first meeting to found the Queen's hospital, and although devotedly attached to the General Hospital, as the scene of his early labours, he not only gave the project his unanimous support, on the public ground "that an additional hospital was called for, from the fact that in this great central metropolitan district, intersected in all directions with railway communications, embracing within its range upwards of half a million of people, employed among the deleterious effluvia incident to many of the manufactures, hourly exposed to accident and disease from powerful machinery assisting the labour of man, and from mining operations, there existed only one such charity, opened in the year 1779, when the population of Birmingham did not exceed 50,000;" and he generously contributed £100 towards the building fund, at the same time accepting the office of Honorary Physician, which he continued to hold until the time of his death. On the incorporation of Queen's College the doctor was appointed the first Principal. In 1844 the Council and Professors presented his portrait to the College, and when, in 1845, accumulating years had warned him to seek that complete retirement which he had so well earned, a special meeting of the Governors, Professors, and Students, presided over by Lord Lyttelton, presented to their venerable head "the earnest and affectionate expression of their gratitude for his valuable and unremitting services" rendered to the institution during a period of eighteen years. To a highly-cultivated mind, and, as we have stated, eminent professional qualifications, Dr. Johnstone united a benevolence of heart, and a peculiar kindness and urbanity of manner, which endeared him to his patients and professional brethren, and won for him the esteem and respect of all classes.

He took an active part in promoting the success of the Provincial Medical and Surgical Association, and at the first meeting, held at Worcester in 1832, he was unanimously elected the President of the Association for the first year of its existence, since which period he has invariably evinced a warm interest in its progress. On entering upon the duties of the presidential chair, on the occasion alluded to, he addressed the gentlemen who were then assembled as follows:—

"As the proposition which you have now so cordially carried is, that I should be Honorary President, I accept it; had it been otherwise than honorary, the period of life at which I have arrived would have forbidden my accepting the office. I subscribe to an expression of one who was most dear to me, 'that the proper termi-

nation of life is when the season of activity and usefulness is past.' From such a termination I hope I shall ever be freed, while any strength or ability remains to serve the interests of my fellow-creatures. I cannot find words to express the respect and gratitude I ever ought to feel to the medical profession, for the kindness and respect I have received from that respectable body since my first entrance into life. I feel I cannot fully utter the feelings of my heart. Since I have been in this room I have had many painful and pleasing recollections rushing through my mind. It is now between fifty and sixty years since I was last within these walls. I was then accompanied by a gentleman whose memory is venerated by you all, and to whom this Infirmary was deeply indebted for the very considerable share of its professional labours which he undertook. He, in the very midst of his days and usefulness, fell a sacrifice to his benevolent exertions in the cause of humanity, by that fatal malady with which this city was then visited, the record of which is familiar to you all. We are now called to meet circumstances of a very similar kind, and it is our duty to meet the case with courage and zeal. Cholera, so novel in its symptoms, so various in its course, which has baffled all medical skill in so many instances, will require the utmost nerve to face it; but we must not shrink from duty in the time of danger;—a physician or medical man who neglects his duty under any circumstances deserves to be shot as much as the sentinel who deserts his post. There are, however, many circumstances which encourage the hope that the laws of the disease will be understood, and brought under the government of medical science. The number of hospitals which have been established by the General Board of Health, and the universal attention paid to the subject, lead us to this conclusion. It is of especial importance that the faculty should pay particular attention to the state of the patient before being taken ill, as it is very evident that the disease is rather a termination of a state in which the sufferer was before the disease seized him."

His remains were interred in the family vault connected with Edgbaston Old Church, being attended by many persons who were anxious to pay a last tribute of respect to the doctor's memory. The body was met at the entrance to Edgbaston Park by the following gentlemen, who there formed a procession, and accompanied the funeral cortege to the Church:—William Scholefield, Esq., M.P., J. E. Piercy, Esq., the Hon. and Rev. G. M. Yorke, and members of the Council of Queen's College, Messrs. Banks, G. Taylor, Harris, Boucher, Watson, Room, and other members of the Committee of Queen's Hospital; Professors Eccles, Davies, Nelson, Sands Cox, Kennedy, Shaw, Berry, Langston Parker, Alderman Palmer, (Chairman,) Alderman Phillips, (Treasurer,) and members of the Committee of the Artizans' Penny Subscription Movement in aid of the funds of the Hospital; Mr. Minshall, (Chairman,) Mr. Pugh, (Secretary,) and members of the Artisans' General Subscription Movement in aid of the same object; members of the medical profession educated at Queen's College; students of the College. The following medical practitioners, resident in Birmingham, had previously assembled in the body of the Church, namely:—Mr. Amphlett, Mr. Blount, Mr. Blake, Mr. R. L. Baker, Mr. Bindley, Mr. Bartlett, Mr. Bull, Mr. Chesshire, Mr. Clayton, Mr. P. H. Chavasse, Mr. R. W. Davies, Dr. Dunn, Dr. Evans, Dr. Elkington, Mr. G. W. Elkington, Mr. Elin, Mr. Field, Mr. Freer, Dr. Fletcher, Mr. Gutteridge, Mr. Harmar, Mr. Hill, Dr. Heslop, Mr. Hoare, Mr. Hayes, Dr. Hinds, Dr. Johnson, Mr. G. Jones, Mr. Jukes, Dr. Mackay, Mr. Middlemore, Mr. Meeke, Mr. Orford, Mr. Partridge, Mr. Russell, Mr. Ryland, Mr. Rice, Mr. Richards, Mr. Robertson, Mr. Swain, Dr. Skerrett, Mr. Simons, Mr. Solomon, Mr. Taylor, Mr. Tarleton. Mr. Tranter, Mr. Wood; Mr. Wickenden, Dr. Waddy, Mr. Ward, Mr. Wilkinson, and Mr. T. W. Williams.

MEMORIAL OF THE MANCHESTER MEDICO-ETHICAL ASSOCIATION.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—We are instructed by the Committee of the Manchester Medico-Ethical Association to forward to you for publication the enclosed copy of a memorial addressed by the Association to the Council of the Royal College of Surgeons of England on the subject of homœopathy.

We are, Sir, your obedient servants,

JOHN AIKENHEAD, } Hon. Secs.
W. C. WILLIAMSON, }

Manchester, Sept. 3, 1851.

To the Council of the Royal College of Surgeons of England.

The Memorial of the Medico-Ethical Association of Manchester,

Respectfully sheweth,—

That a large majority of your memorialists possess the diplomas of your College, either as fellows or members.

That your memorialists have learned that upwards of fifty members of the College are engaged in the practice of homœopathy in London and the provinces, and that the number is on the increase.

That your memorialists also regret that there are practitioners who for the most part are entitled to the highest respect of their fellows, but who, under some distorted notions of propriety, have become the abettors of this apostacy on the ground of diagnosis.

That your memorialists, since the formation of their Association, have been restrained by one of its by-laws from all professional intercourse with homœopathic practitioners.

That, while your memorialists would emphatically commend the passive resistance which the medical profession has hitherto offered to this system of imposture and delusion, they believe the time has now arrived when the dignity of the College to which they belong must be vindicated, and the honour of its members shall cease to be degraded by ignominious associates.

That your memorialists are encouraged to press this subject on the attention of the Council, by the fact that the Royal College of Physicians of Edinburgh, in a resolution recently adopted, "expresses an earnest hope that those fellows, seeing they have virtually separated themselves from the College, will spontaneously sever their further connection with an institution that repudiates them, and from which they can derive, as merely fellows, nothing else than a false position, and a spurious credit."

That your memorialists would suggest that, in imitation of this resolution, the Council exercise the power conferred by clause 3, section 20, of the by-laws of the College, of removing from the list of members any person who has rendered himself disgraceful to the College; and that the Council also protest against the unworthy association of scientific practitioners with homœopathists on the fallacious ground of "diagnosis."

That your memorialists will ever aid in upholding the ethics of a College whose honour and dignity are outraged, and whose members are insulted.

J. L. Bardsley, M.D., President.
John Aikenhead, W. C. Williamson, } Hon. Secs.

Manchester, September 3, 1851.

Correspondence.

ON THE DUTY OF THE PROFESSION WITH REFERENCE TO HOMŒOPATHY AND THE OTHER QUACKERIES OF THE DAY.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—If an earnest desire to advance the honour and well-being of my profession forms any justification for the expression of opinions which do not seem to be those of a large majority of my brethren, as recently put forth, I, at least, may claim an indulgent hearing while I endeavour to set before you my views on the present aspect of orthodox medicine as opposed to the fashionable heresies of the day.

I was present at the recent meeting of the Association at Brighton, and was originally proposed to form one of the Committee to draw up the "Report on Irregular Practice." I declined that honour for reasons which will be sufficiently obvious as I proceed.

No one can deny the reasonableness and propriety of the present attempt to get rid of homœopathists from our Universities and Colleges. They are quite at liberty to have Universities and Colleges of their own. All we desire is that they shall be separate. No good can come of their being united. They repudiate the fundamental principles of our belief, and we do not acknowledge theirs. A true Hahnemanic disciple ought as unequivocally to reject our knowledge, and the degrees, which are merely the evidence of that knowledge, as we should degrees in globulism. Let them have a Hahnemann College; a small foundation I apprehend will be sufficient; and then I think I can guarantee them freedom from molestation on our part.

But, while I think the movement on the part of our Universities and Colleges wise and necessary, I entertain very grave doubts as to the wisdom of our late proceedings at Brighton. The public cannot and will not see empiricism from the same point of view as we do;—denunciations of homœopathy, apart from any evidence of its fallacy, never can do any good. Towards the public homœopathy appears simply as a new medical sect struggling to supplant the old one in general estimation; and whatever hard names we may apply to its professors will not injure them, but far more probably fall on our own heads. Strong language will be looked on as the evidence of a weak cause, and not as the utterings of an indignant spirit at proceedings unworthy the pretended votaries of science. Let us cast our eyes backwards over the course of time, and see if any person or thing has ever been too insignificant to be persecuted into notoriety for a period.

The question at issue has a wholly different aspect when applied to our Universities and Colleges, and when applied to bodies such as our own Provincial Association. The former have entrusted to them the education and licensing of aspirants to medical practice; and it is a reasonable and essential part of their duty that they shall keep pure the fountains of knowledge over which they preside;—that truth and falsehood shall not appear to them as things indifferent, by their sending forth to the world, with the seal of their approbation, men holding dogmas which they believe to be not only false but dangerous to the community; for it must not be forgotten that medicine is not only a creed, but it is a practice founded on that creed. The Provincial Association, on the other hand, is a body of men banded together for the advancement of medical science,—for the promotion of just and honourable dealings in their intercourse with one another,—and for the interchange of the courtesies and amenities of life. These are objects abundantly worthy of our best energies for their furtherance; but I think we step altogether out of our province when we pronounce judgment on the proceedings of those who are not of us, and who are, besides, out of the pale of the profession. It is the clear right of every adult person to choose their own adviser in time of sickness. Some will choose the homœopathist, and some the hygièst; and this they will do irrespective of our approval or the contrary.

I now proceed to offer a few remarks on what I believe to be the only proper mode by which the profession generally can oppose homœopathy; that is, by individual influence. The sarcastic epithet, and the contemptuous smile, must give place to courteous and intelligent reasoning. And in order to this end, medical men must not think it beneath their notice, nor the trouble too great, thoroughly to inform themselves as to what homœopathy really is. They must understand it in its theory and in its practice. It will not do in conversing on the subject with a layman to denounce the whole system as humbug, and those who practise it as impostors; this may save much trouble, but it will make no friends. We must listen to their difficulties however peurile they may be; we must hear their

reasonings be they ever so absurd; and then our answers must be calm, full, and explicit. I would urge strongly on all those who do not possess the temper, or who will not take the trouble, thus to inform themselves, to keep silence when homœopathy is under discussion; otherwise, they will only injure the cause which their zeal prompts them to serve. Many men of great intelligence among the public have adopted homœopathy, they are well informed as to what can be said in its favour, and they are not to be convinced of their error by shoulder-shrugging, and denunciatory epithets. I will take the liberty to quote here the conclusion of a paper I read before the Bath and Bristol Branch of the Association, in March of last year, on "A case of Cataleptiform Hysteria, apparently induced by Mesmerism." "In these—the flourishing days of empiricism in every form, I conceive it to be no less the duty than the interest of the legitimist in medicine to make himself acquainted with the doctrines of the leading quackeries afloat, so as to enable him to give a reason for their rejection to those who inquire of him concerning them. It is neither wise nor in good taste to be always thrusting our denunciations of this or that empirical system into the teeth of those who believe in them; by so doing we add strength to the delusion. Unless we are appealed to for an opinion, all that is demanded of us is a calm indifference; and if our opinion is asked, as so frequently happens, I believe we shall best consult the interest of legitimate medicine by admitting frankly whatever of truth the particular system under discussion may appear to us to contain, and by pointing out dispassionately where we consider truth to terminate, and fiction to commence. By so doing we shall let it appear that our rejection of the system has not arisen from prejudice, or from a want of attention to its claims, but because it presents, along with a less or greater substratum of truth, a huge superstructure of assumption and of falsehood." This may suffice to show that the plan of dealing with homœopathy which I have now proposed for the consideration of the profession, has not only occurred to me to fit the present occasion, and I may further observe, that I have put this plan in practice on some few occasions with sufficient success to justify my recommendation of it to others whose opportunity is much larger, as their ability to do it justice is much greater than mine.

In conclusion, I would earnestly entreat of my professional brethren to pause before they give occasion to the followers of Hahneman to get up the whine of persecution. There is no way by which we can so effectually serve their purpose as by making seeming martyrs of them;—by enabling them to go before their noble patrons with the cry of persecution in their mouths;—by enabling them to proclaim themselves sufferers and victims in the sacred cause of truth—they will become at once Galileos, and we shall be the enchainers of the human mind.

I am Sir, your obedient Servant,
WILLIAM DAVIES, M.D.,
Physician to the Bath United Hospital.

Bath, August 27, 1851.

DR. WEBSTER ON MEDICAL REFORM.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—As I could not possibly attend the general meeting of our Association at Brighton, I addressed a letter to Sir Charles Hastings, with a request that it might be read at the Council, and also at the the public meeting, unless material alteration should be made in the Report respecting Medical Reform.

I understand by a note from Sir C. Hastings "that he read it to the Council, and they unanimously came to the decision that my letter, as well as some others which were sent to him and to the Secretary for that purpose, should not be read at the public meeting."

As I am wishful to have an opportunity of placing my opinions before my colleagues of the Association, and believing that many of them, and a large majority of the general practitioners of England and Wales entertain similar sentiments,—though they may differ from those of some of the leaders of the Association—you will much oblige me by publishing my letter in the next number of our *Journal*.

I am, Sir, your obedient Servant,
GEORGE WEBSTER.

To Sir Charles Hastings, M.D., &c.

My dear Sir,—I am hourly expecting an anxious midwifery case, which, if not over in time, will deprive me of the pleasure of attending our anniversary meeting at Brighton. I shall regret this the more, because I particularly wish to be present at the Council meeting on Tuesday evening, to suggest some alterations in the proposed Report of the Council.

In case of my absence, therefore, I write to protest respectfully, but earnestly, against the course indicated in the Report on the question of Medical Reform. Should the Council propose, and the members present at the anniversary "accept the proffered terms of the College of Surgeons, with some slight *modifications*," "as the basis of a *final settlement* of the question," they will, in my humble opinion, show a great amount of gratitude for very small concessions, while they will betray the rights and interests of a great majority of the Association and of the profession. Such a scheme may probably meet the wishes of those who are anxious to become *fellows* of the College; but as regards the degraded *members*, they will gain nothing, unless they acquire full, free, and unrestricted votes in the election of the Council, and be also themseves eligible to seats on the Council. It appears to me as if the Central Council of the Association had considered chiefly the privileges of the fellows of the College, and forgotten the claims of other practitioners. The great majority of medical men are not consulting but general practitioners, and whether members of the College of Surgeons only, or licentiates of the Society of Apothecaries, or both,—or holding other diplomas and licences in addition to these, or without them,—they must be viewed as *one body*, and their rights and interests as *identical*. I consider, then, that the new proposal (which you and your colleagues of the Central Council approve of) to

take from the general practitioners the power to regulate the education and test the qualifications of their own body, and confer it on the Colleges of Physicians and Surgeons would not only be a flagrant act of injustice, but would be fraught with great danger to the public health.

Is it in accordance with our experience of human motives and corporate actions, to believe that the Colleges would ever view with favour, or govern with equity, the general practitioners of this country, whose interests are opposed to their own, and who have been called into existence by the wants of the public, in direct opposition to the intentions and wishes of these bodies? Is it for a moment to be supposed that the Colleges, who have erected, and are still erecting, barriers between themselves and the general practitioners, by examinations, fellowships, and distinctions hitherto unknown,—so that one class shall appear to be a very superior body, and the other a very inferior one,—is it to be supposed that they will be anxious to enlarge the curriculum, raise the qualifications, or elevate the *status* of the general practitioner? Undoubtedly not. And thus the public will be deprived of the manifest advantages which a friendly rivalry and professional emulation would naturally produce among the different bodies from self-government and the power to test the qualifications of their own members. Self-government is the first law of society, and why should one body legislate for or govern another? What do we see when such an unnatural system exists? We see confusion, discontent, degradation, oppression, and continual agitation—the governing section trampling upon the governed, and, as I have said, with loss to, and neglect of, the public interests.

You are aware that my own feelings and convictions have long been in favour of a single "Faculty of Medicine and Surgery," as the most natural and just arrangement for all parties; but after years of fruitless efforts for its attainment, a large body of reformers, comprising numerous Associations, determined, that as the general practitioners were unrepresented and uncared for in the Colleges, the next best step to a Faculty of Medicine would be a Royal College for their own government and examination. "The so-called concessions of the Council of the College of Surgeons" are certainly not sufficient to satisfy even their own members, who are to have no votes and no participation in the management of the College—these being reserved for the favoured fellows only; far less ought the general practitioners who are not members of the London College to be satisfied with a plan which would place them under the step-mother government of bodies who have always been opposed to them.

The Report states that all the accredited Associations had been consulted, and had agreed to the proposed plan! I protest on behalf of the National Institute of Medicine, Surgery, and Midwifery, as being directly opposed to such a scheme; and I believe they will not cease to agitate the question until the general practitioners obtain self-government and the right to test the qualifications of their own class, either in a College of their own, or in conjunction with the present Colleges, as part of a general plan for the whole profession.

The Report also entirely overlooks the Society of Apothecaries, though in one of the memorials to Sir George Grey, it is assumed that "they have very laudably expressed their willingness to resign into competent hands the management of the examinations in medicine and pharmacy." I believe the Society do not consider the Colleges either *safe* or competent hands, and that they will not *willingly* resign their powers, which have been so beneficial to the profession, into any hands but those of their own class.

While so much opposition has arisen from some of the provincial surgeons and physicians, to the Royal College of General Practitioners, and whilst strong objections have also been made by the College of Surgeons, it is remarkable that all parties should have been so apathetic as regarded the proposed Pharmacy Bill, which would have created new vested rights, and added another element of discord in the settlement of the medical question. The Pharmacy Bill would have created a Royal Pharmaceutical College, which, with a very slight addition, would soon have become in reality a *College of General Practitioners of a very low grade*, to the detriment of the public. Surely the Society of Apothecaries, the long-established and legal regulators of pharmacy, are perfectly fit and competent to test the qualifications of chemists and druggists without the creation of another College to make confusion worse confounded.

I am happy to be able to entirely concur in the other parts of the Report, and especially in that which refers to the false lights of homœopathy, hydropathy, and mesmerism; and I heartily trust that a strong resolution will be passed at the general meeting to cleanse the Association from the pollution of all practitioners of these and similar quackeries. Allow me to add one word as to the annual volume of *Transactions*. I hope that in future it will be issued at an earlier period of the year, and in the old form, bound in cloth, so that it may neither be a disgrace to the Association, nor run the risk of being torn and otherwise injured in its passage through the Post-office.

With every good wish for a pleasant meeting, and regretting my own unavoidable absence,

Believe me, my dear Sir Charles,

Yours very faithfully,

GEORGE WEBSTER.

P.S.—I hope you will allow this to be read at the Council meeting, and also at the general meeting, should no material alteration be made in the Report. G. W.

Dulwich, August 11, 1851.

KOUSSO AS A SPECIFIC FOR TAPE-WORM.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I perceive in your report of the Brighton meeting, that Dr. Crisp read a paper to prove that "Kousso was not a specific for tape-worm." The cases recorded in this country are yet assuredly too few to allow its denomination as a *specific*; they are, however, sufficient to permit its appellation as a *valuable remedy*. I will add one to the number.

A young woman was lately admitted into the York County Hospital, who had long been distressed with tape-worm, for which various remedies, including turpentine, and male fern, had been given, without procuring any relief. One dose of kousso—that is to say, half an ounce of the dried flowers given in half a pint of tepid water—expelled the worm whole. Some days afterwards, not feeling thoroughly satisfied, she requested another dose might be given, which she took, but in vain; it would seem there was no worm to be expelled.

She left the hospital highly delighted, expressing a hope she might be re-admitted "should it grow again."

The medicine was by no means disagreeable to take; the price of the dose, rather so, being ten shillings; but it is probable a larger quantity will be imported, and the price more regulated. Perhaps you could afford some valuable information upon this point."

If individual cases were recorded its value would soon be ascertained.

Dr. Nevins says:—"It is the most efficient remedy for tape-worm with which we are yet acquainted."

I remain, Sir, yours very truly,

H. S. BELCOMBE,

Senior-Physician to the York County Hospital.

Minster Yard, York, August 31, 1851.

DR. MAYNE'S EXPOSITORY LEXICON.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—My intention of publishing, by subscription, an "Expository Lexicon of the Terms in Medical and General Science," is probably well known, from the pretty extensive issue of prospectuses, &c., among the members of the profession in England and Scotland. As, however, a complete circulation of these is more than one pair of hands, actively engaged in the duties of general practice, can accomplish, I respectfully, and I trust legitimately, seek the aid of your columns in furtherance of that intention.

The proposed lexicon is the produce of more than twenty years' labour, intended to supply what at that remote period I, as a student, felt to be the greatest stumbling-block in my way,—the want of a proper explanation of technical terms, without which the illustrations of the lecturer were unprofitable, and often egregriously misapprehended. To this hour the same want is felt, and not only by the student, but also by the practitioner, there being no English work similar to my "Expository Lexicon" in extent, character, or arrangement, in existence.

I feel very grateful in acknowledging the courtesy, the encouraging terms of approbation of my work, and the good wishes with which I have been honoured by many of those who occupy the highest places in professional rank. The different constitution of men's minds, however, but perhaps especially the disappointments met with in other works promised in parts, are sad hinderances to the promotion of my enterprise. The reasons assigned for not aiding me are,—some think that there are already plenty of lexicons, and for those who so judge there doubtless are; some excuse themselves by saying they are too old to buy or to need new dictionaries. I have been told that personally waiting upon my professional brethren in town and country is the most efficient mode of obtaining subscribers; and I believe it is so. But the cost of time which such a course involves is incompatible with the daily avocations of a general practitioner, to say nothing of the toil and (in some instances) unpleasantness.

I presume not to offer one word commendatory of the work itself. Were it to prove altogether a failure, the attempt, at least, to do for medical scientific language what has not before been done would seem to merit some countenance from medical men. That attempt absorbed all my leisure hours; I have expended on it much labour with, I now feel, no small amount of health; and I am bold enough to think that these things give me a title to more than a mere buying effort,—to the kindly co-operation of my brethren in forwarding the result, which, if any value at all, must be regarded as important in a special degree to the entire medical profession. I seek no pecuniary favour, no gratuity, but simply the warrant of a sufficient number of names as subscribers to justify me in bringing out a work too large to be otherwise ventured on. The MS. is completed, and has been shewn to influential members of the profession, as a guarantee for the regular appearance of the parts whenever the number of subscribers shall give a sanction to my going to press. I have already obtained about eighty names, and two hundred more are wanted. In the hope that this communication may meet the eye of some among the many thousand members of our profession who are inclined to aid me, I venture to ask for it a place in the *Provincial Medical and Surgical Journal.*

I am, Gentlemen,

Your obedient Servant,

R. G. MAYNE.

Leeds, September 6, 1851.

[From the specimen that was sent us, we can strongly recommend the above work to all those who are concerned in the education of the rising generation. It will supply a want which all must often have felt in their younger days, and perhaps, also, more recently.—Ed. Journ.]

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—In the last number of "Household Words" there is an article on the treatment of the insane, which concludes with the following sentences:—"But having intimated that the existing arrangements for the accommodation of private patients are generally defective, we conclude with the expression of a hope that we may yet witness the establishment of a system into which speculation, in the hope of private gain, will not be allowed to enter, or will be far more stringently restricted than it is at present." I hesitate not to say that the writer must have seen very few private establishments, or that he is unfair in his deductions. The

continued domiciliary visits of Visiting Magistrates and of Commissioners, under the Lunatic Act, must prevent any tampering with the necessities and comforts of a patient; besides, many of the inmates are ready enough to bring forth some fancied grievance, and many visitors equally ready to believe them, even against positive evidence to the contrary.

Again, the Chancery Law is very defective. As the writer of the article truly says, Chancery will take care of the estate, but troubles itself little about the body. The allowance is sometimes very inadequate.

I am the proprietor of a small private estabtishment. I had under my care a gentleman, a ward in Chancery, an idiot, (but understanding well the conveniences and comforts of life,) unmarried; his estate ample, unincumbered, and to pass at his death to a distant relative. £300 per annum was all that was assigned to me for his *entire* maintenance.

I do not mean this letter to be a long one; but I wish to renew the subject, if you will permit me, by inserting my letters. For the present I will only say, I consider the proprietors of private establishments a very aggrieved body; and I feel astonished that some endeavour to open out this question has not hitherto been made.

At present I desire to withhold my name, but I send you my card. Yours obediently,

E. B.

September 4, 1851.

MR KENWORTHY'S CASES IN MIDWIFERY.

To the Editors of the Provincial Medical and Surgical Journal.

Sir,—In the *Journal* of the 3rd instant, there is a paper read by me at the meeting of the Lancashire and Cheshire Branch of the Association, held in Manchester, 25th of June last, (not at Brighton,) and you will allow me to call your attention to a material discrepancy.

Case 8.—Mrs. O., December 11, 1850.—The following extract is copied from the manuscript:—"I introduced my hand very slowly round the placenta, grasped the child's feet and waited an hour, got some brandy and opium into her stomach in tea, she took Tr. Opii, f℥iv., during the first twenty minutes; a feeble rallying of the pulse now evidenced, and I drew away the child very quietly a little after five P.M."

In the *Journal* it is rendered thus:—I introduced my hand very slowly round the placenta, grasped the child's feet, and *after waiting* an hour got some brandy and opium into her stomach in tea."

The brandy and opium were administered during the interval of waiting and I ought to have specially mentioned it. May I request you will correct this in your next publication of the *Journal*.

I remain Sir, respectfully yours,

JOHN KENWORTHY, M.R.C.S.

Strangeways, Manchester,
September 8, 1851.

ADDRESS FROM THE MEDICAL PRACTITIONERS OF GUERNSEY TO THE COMMITTEE ON IRREGULAR PRACTICE.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—I have been requested to present the enclosed to the Committee on Irregular Practice; but I hope you will agree with me in thinking that so important a communication ought not only to be laid before my colleagues in the Committee, but also (without waiting for our annual meeting at Manchester) before every member of the Association, through the columns of the *Journal*.

Allow me to embrace this opportunity of stating, for the information of members, that the Report on Homœopathy, and a full report of all the speeches delivered upon the occasion of its adoption, may now be had through any bookseller for 8d., or from Mr. Churchill, the publisher, free by post, for 1s. Members taking 50 or more copies, and intimating their wishes on this subject to me before the 1st of October, may be supplied at the rate of 7s. 6d. for fifty, and 15s. for one hundred copies. As the last edition of 1,500 is almost exhausted, the types are still kept standing till the extent of the third edition be determined. Applications must be made before the 1st of October, but, if possible, at once.

It must be gratifying to the Association to learn that since the resolutions were published I have received above one hundred letters from medical practitioners in all parts of the United Kingdom, approving very heartily of them, and particularly of the *fourth*, in which three classes of practitioners are marked out as unfit to be members of our Society.

I am, Sir, your obedient Servant,

JOHN ROSE CORMACK.

Putney, Sept. 12, 1851.

The following is the communication from Guernsey referred to by Dr. Cormack:—

TO THE COMMITTEE ON IRREGULAR PRACTICE OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

Guernsey, September 10, 1851.

Gentlemen,—We, the undersigned, medical practitioners of the Island of Guernsey, beg to offer our warm congratulations, and sincere thanks, to the Provincial Medical and Surgical Association in general, and to you as their Committee in particular, for the manly and straightforward resolutions unanimously adopted at a meeting of that body, held at Brighton on the 14th ultimo.

We likewise desire to express our cordial approval of the uncompromising tone of the speeches delivered on that occasion, when, in our humble opinion, the principles of truth, honesty, and morality, were elucidated, the science of medicine vindicated, and the injurious tendency of homœopathy—its hollowness, absurdity, and dishonesty—demonstrated by clear, comprehensive, and irrefragable facts.

We would fain hope that the dignified manner in which the Association has responded to the movement

of the Universities of Edinburgh and St. Andrew's, to expose and discard homœopaths, will be followed by the English and Irish Colleges, and thus enable Great Britain to set as bright an example in checking error, and upholding truth in medicine, as she has recently done in religion.

We derive additional satisfaction in addressing the Provincial Medical and Surgical Association, from having throughout firmly, advisedly, and conscientiously resisted all attempts to induce us to hold intercourse with homœopathic practitioners, or to countenance a system the offspring of quackery, the refuge of imposture, and the nursling of dupes.

We now calmly wait the course of events, satisfied that truth and honesty will prevail, and that homœopaths who seek to be considered as regular practitioners, and pertinaceously shelter themselves under the ægis of medical institutions, will ultimately be exposed and repudiated.

We have the honour to be, Gentlemen,
Your obedient Servants,

John Mauger, M.R.C.S., Eng.
J. Elliot Hoskins, M.D., F.R.S.
M. Maygarth Bresh, R.N.
De Beauvoir De Lisle, M.D.
Thomas L. Mansell, M.D.
John Roberts, M.R.C.S., Eng.
R. G. Carey, M.D.
Fred. C. Lukis, M.R.C.S., Eng., M.D.
M. A. Bazille Corbin, M.R.C.S., Eng.
B. Collenette, R.R.C.S., Eng.
Martin Mauger, R.R.C.S., Eng.
Polydore Tranter, M.R.C.S., Eng.
J. Baines, M.R.C.S., Eng.

Medical Intelligence.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Members, on Thursday, August 28th:—John Billerwell Gibson, Exmouth Street; Maurice Thomas West, Tenby, Pembrokeshire, South Wales.

Gentlemen admitted Members, on Thursday, September 4th:—John Le Gay Brereton, Doncaster; Charles Denton Hulme, Leicester; John Rolston, Devonport; Thomas Henderson Somerville, Sedbergh, Yorkshire.

BOOKS RECEIVED FOR REVIEW.

On the Spine and Paralysis. By Charles Verral. London: John Churchill, 1851.

Memorials of Dr. John Mackness. London: John Churchill, 1851.

London Journal of Medicine, September, 1851.

American Journal of the Medical Sciences, July 1851.

The Charleston Medical Journal, July, 1851.

OBITUARY.

Sept. 9th, at Worcester, in the 93rd year of his age, John Raymond, Esq., for many years an active member of this Association.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NEW MEMBERS OF COUNCIL.

In addition to those gentlemen whose names were added to the General Council at the late Anniversary Meeting, at Brighton, we omitted to mention the following:—

W. E. Crowfoot, Esq.	...	Beccles Suffolk.
Frank Renaud, M.D.	...	Manchester.
Robert Wake, M.D.	...	Southwold, Suffolk.
Robert Uvedale West, Esq.		Alford, Lincolnshire.

SUFFOLK BRANCH.

Mr. C. R. Bree, of Stowmarket, having resigned his office of local Secretary to the above Branch, all letters in connection with the Suffolk Branch must be addressed to Dr. Kirkman, of Melton, Suffolk, who has been appointed his successor; it is therefore requested that all those gentlemen, (members of the Suffolk Branch), who have not yet paid their subscriptions for the current year, will be good enough to forward the same to Dr. Kirkman.

YORKSHIRE BRANCH.

Mr. W. Matterson, of York, has succeeded Mr. W. D. Husband as local Secretary to the above Branch; all letters and communications in connection with the Yorkshire Branch must be addressed to Mr. W. Matterson, and all members of that Branch who have not yet paid their subscriptions for the current year, are requested to transmit them to Mr. Matterson.

SHROPSHIRE BRANCH.

Mr. Humphreys, of Shrewsbury, has been associated with Dr. Drury, of that place, as joint local Secretary. All communications in connection with the Shropshire Branch may be addressed to either of those gentlemen, and by whom subscriptions and arrears will be received.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, September, 1851.

Errata.—In a case appended as a note to Mr. Humphrey's lecture, there is an error in the punctuation. At page 480, col. 1, line 2, from the bottom, a full stop should follow the word "intention," the word excepting should commence a fresh sentence, and there should be a comma only after "degree." Thus:—The arm was amputated and the stump healed by first intention. Excepting at one point, and that to a doubtful degree, the disease did not extend beyond the integument of the arm.

TO CORRESPONDENTS.

Communications have been received from Mr. Propert, Mr. Simpson, Mr. Humphry, Mr. Harvey, and Mr. E. Bishop.

A COURSE OF LECTURES ON SURGERY,

DELIVERED IN THE MEDICAL SCHOOL OF CAMBRIDGE.

By GEORGE MURRAY HUMPHRY, Esq.,

Downing College, Surgeon to Addenbrooke's Hospital.

Lecture XXXII.

Scirrhous and Encephaloid Cancer.

Characters of scirrhous tumours; certain growths in their minute structure resemble fibrous tumour, but present the general characters of cancer, and should therefore be regarded as scirrhous; scirrhus of intestinal mucous coat an example of this; tendency of tissues affected with scirrhus to contract: the term "scirrhus" should be applied only to induration of a cancerous nature; diagnosis of scirrhus from inflammatory induration in the breast, in the intestinal canal; ages, persons, and parts most liable to be affected by it.

Characters of encephaloid tumours; extravasations of blood in them; presence of cartilage in them; they are occasionally invested with capsules; they become "fungous;" persons and parts most liable to be affected with them; osteo-encephaloma; difficulties in the diagnosis of encephaloid disease.

Having entered somewhat at length into the subject of malignant disease generally, and of the epithelial variety of cancer, I shall not detain you much with the other varieties that have been enumerated, because you have abundant opportunities of clinical instruction with regard to the most important of them, and because I have little information to communicate, which is not contained in the ordinary treatises upon this subject.

The "scirrhous" and "encephaloid" or hard and soft varieties of cancer present so many points of correspondence in their general features, that it seems better to consider them under one head. Both consist of cells and molecules contained in the areolæ of a fibrous stroma; the chief difference depending upon the relative proportion which these constituents bear to one another. The cellular element predominating in the encephaloid, the fibrous element in the scirrhous cancer. The well-marked examples of each are sufficiently distinct to the eye and the touch, but the interval between these is filled up by a closely-connected series of specimens, many of which we are unable to refer to either species. Moreover, it not uncommonly happens that we find cancer in different organs of the same patient, which approaches both to the scirrhous and to the encephaloid type; or it may be, that in the same cancerous tumour one portion resembles encephaloid whilst another is more nearly allied to scirrhus.

A "scirrhous" tumour is usually a hard, heavy, nodulated mass, blended with the surrounding tissues, which run into and are lost in it; or they may be condensed and adherent to it. It grates under the knife, and its section has a pale, glistening, or dull white colour. Very often it is marked with streaks or bands more opaque than the rest of the mass, interlacing together and dispersed without any regular arrangement. Sometimes a number of yellowish white soft spots are scattered through it; or there may be small cavities containing a purulent fluid. A certain amount of fluid oozes, or may be compressed, from its cut surface. When the tumour is very hard this is scanty, thin and pale, like serum; if the tumour be softer, the expressed fluid is more abundant and has a creamy appearance. In either case it contains cells, nuclei, and granules, with the addition, often, of corpuscles. The distinctness with which the fibres or bands are visible to the naked eye varies a good deal. In some instances they cannot be seen at all, the mass presenting an uniform, hard, brawny, cartilage-like appearance; or it may be composed of pale glistening grains closely compressed together, without any show of interlacing bands and fibres. In other cases, more particularly in cancer of the liver, you may see a reticulum of coarse, thick, tough bands, radiating, perhaps, from the centre to the circumference, like the spokes of a wheel, or disposed without any definite arrangement, and including in their meshes a soft, yellowish, or creamy fluid.

When a thin section is examined under the microscope, it is found to consist of a meshwork of fibrous tissue, forming wavy bands, which are sometimes arranged in circles, but generally are disposed without any apparent order. The circles or meshes enclose a fluid containing nucleated corpuscles and granules. The whole structure is rendered more transparent by acetic acid, which has the effect of partially or completely dissolving the walls of the corpuscles, so rendering the nuclei more visible. In its minute structure, therefore, a scirrhous tumour differs from a fibrous, mainly if not entirely, in the presence of cancer cells, infiltrating between its component fibres. I do not mean to say that it is the only *real* difference between the two growths, because, as has been already stated, it is probable that the malignant qualities—the tendency that is to ulcerate and spread—are not confined to the cells alone, but they are shared, though in a far less degree, by the fibrous tissue also. This is an important point to bear in mind in connection with the fact that the cell-element varies very greatly in its relative proportion to the fibrous element in different specimens of scirrhus. In some instances the cancer cells can with difficulty be distinguished from the developmental cells of the tissues, and in some there is reason to suppose that they are absent altogether, although the tumour may still present the genuine qualities of cancer. It is important, I say, to remember that the malignant qualities of cancer are shared by the fibrous tissue, as well as by the cells entering into its composition, because it seems to afford an explanation of those cases, where tumours supposed to be fibrous, and presenting to experienced observers the anatomical, microscopical, and chemical characters of fibrous tumours, have returned after complete extirpation, have proceeded to sloughing and ulceration like

ordinary cancerous growths, and have infected distant organs. Specimens of tumours which were regarded to be fibrous, and which took the course just mentioned, are described in the catalogue of the Museum of the College of Surgeons. One of the patients, whose case is there related, I had the opportunity of examining before the operation was performed, and the general characters of the growth certainly appeared to me to betoken scirrhous rather than fibrous disease. I should imagine that some of the cases described by Dr. Bennett under the title of "fibro-nucleated cancroid growth," are of the kind of which I am now speaking, being composed of filaments infiltrated with oval nuclei, constituting a densely fibrous texture, which grated under the knife. Yet these tumours grew quickly, involved the adjacent textures, were liable to softening and disintegration, and, if excised, returned at the place originally affected. They presented, in short, the usual general characters of scirrhus, though in their microscopical structure they were more nearly allied to fibrous growths. In referring such cases to the pathological division which they should occupy, and in ranging them among simple or malignant growths, we must rely either upon the general or the microscopical characters which they present. The reasons for preferring the former have been given in a preceding lecture; and it certainly does seem the best practical arrangement to include in the same class those tumours which present the great general features of cancer, although they may not quite agree in their minute structure.

I have already called your attention to another instance of the same kind, viz., the thickened, indurated, condition of the muscular coat of the intestinal canal, which accompanies scirrhus. The absence, nearly complete, of cancer-cells in the tunic thus affected, has caused great doubt as to the real nature of the disease. By some pathologists it has been thought to depend merely upon hypertrophy; by others it is regarded as an inflammatory induration. The peculiar stony character of the induration, sufficient to cause a grating under the knife; its usual association with cancer of the mucous membrane of the adjacent absorbent glands and of the other parts of the body; the period of life and circumstances under which it occurs; its liability to softening, ulceration, &c., are characters so well marked, and so clearly attaching the disease to scirrhus, as to leave no doubt of its real nature upon my mind. I may mention that the position which this scirrhous induration is found to occupy, is a point of much practical importance, enabling us in many instances, to distinguish during life those strictures of the alimentary canal which are sure to prove fatal from those which admit of alleviation by treatment. Thus the simple or inflammatory strictures are found, as has been mentioned in a former lecture, exclusively, or almost exclusively, near the terminations of the canal, that is to say, at the upper part of the œsophagus, and at the lower part of the rectum. The malignant strictures, it is true, occur at these parts, but they are not confined to them. They are often found at the lower part of the œsophagus, in the stomach, very often at the pylorus, sometimes in the upper part of the rectum. Here is a specimen of scirrhous disease of the muscular coat at the sigmoid flexure of the colon. You observe the thickened, indurated, striated condition of the tunic, and the narrowing of the intestine at the part; the submucous tissue is free, and the mucous membrane preserving nearly a healthy condition, is puckered into longitudinal folds, where it passes through the stricture; the neighbouring absorbent glands are enlarged and greatly indurated. The specimen was taken from a woman who had passed the middle period of life, and who died of the disease. Here is a specimen of the same disease affecting the terminal part of the ilium and the ilio-cœcal valve in very much the same way, except that the submucous tissue is involved, and the mucous membrane is in consequence adherent to the thickened and indurated muscular tunic. In this third specimen, taken from a man aged 55, the disease, situated at the junction of the ascending with the transverse portion of the colon, has advanced farther; the mucous membrane being itself involved and destroyed, and a considerable ulcer, with raised everted edges produced; the muscular coat is also in part destroyed. Constriction of the small intestine between the duodenum and the termination of the ilium from either inflammatory or scirrhous induration of its tunics is, I believe, very rare.

A remarkable and important feature connected with the scirrhous conversion of tissues is the tendency of the affected part to contract, much in the same way as cicatrix or recently effused lymph. It is this which gives rise to narrowing of the bowel, or stricture, when the muscular coat is diseased, after the manner seen in the specimens just shown. The same contractile tendency causes the retraction of the nipple when the ducts of the mammary gland are becoming converted into scirrhus, and the close adhesion of the integuments to the breast, when the bands of fibrous tissue passing from one to the other are involved in the same way. This, no doubt, contributes also much to the hardness of scirrhus, and explains many of the phenomena observed in organs affected by it.

Much confusion has arisen, and many erroneous notions have been occasioned, by the vague indefinite manner in which the term "scirrhus" has been used, which, it must be confessed, is warranted by the literal meaning of the word; for it signifies merely, hardness or induration, and is often used to express that only. Most accurate pathologists of the present day, however, employ the term to indicate the variety of hard cancer which we are considering, and it is, therefore, obviously most desirable that the word should be used in that sense strictly, that it should not indicate merely induration, but, in an especial manner, induration of a cancerous nature.

The diagnosis of scirrhous affections, in an early stage, from the swellings, indurations, and contractions, resulting from simple inflammation, is of great practical importance, and, in many instances, of considerable difficulty. You are aware that scirrhus very frequently attacks the mammary gland, and on this account females are, with good reason, suspicious of any swelling

or induration, or, indeed, of any complaint affecting that organ; and you may expect very often to be called upon to give an opinion respecting diseases of the breast, and will be particularly and anxiously questioned whether the disease is, or is likely to become, cancerous. In the greater number of cases it is easy enough to give a decided and correct answer to the question; but there are many instances in which it is very difficult, if not impossible, to do so. Patients, whose age ranges from 20 to 50, are frequently presenting themselves at the hospital with a lump in the breast, which is most commonly situated on the outer side of the nipple. The lymph is clearly distinguishable by the touch, and gives to the finger the impression that it consists of slight enlargement, with induration and cohesion of the mammary globules; the skin over it may or may not be adherent, and slightly discoloured, and the nipple may or may not be drawn a little towards the part. The part is rather tender, and is usually painful, the pain being very often represented of a pricking or darting character. The patient states that the lump has existed for two, three, four, or more months, and that it gradually increases, and becomes more painful. Now these are the symptoms which commonly attend chronic inflammation of a part of the breast, and this is the way in which scirrhus usually begins. Many circumstances, it is true, assist us to discriminate between the two diseases, such as the age and general appearance of the patient. The inflammatory affection is common at every period in the interval I have mentioned, and, though very generally associated with some disorder of the digestive or uterine function, is quite compatible with soundness of health. Scirrhus occurs most commonly, though not exclusively, towards the decline of life, and is usually associated with some evidences of failure in the nutritive forces, such as wasting or weakness, sallowness of complexion, change of colour in the hair, &c. Moreover, the scirrhous lump is, for the most part, better defined, and more stony than the inflammatory, and it is often attended with enlargement and induration of the absorbent glands. Nevertheless, errors are continually being committed by the ablest surgeons in attempts to make a diagnosis between these two affections, which should induce you to study both diseases attentively, and to weigh the symptoms well in each case before you give a decided opinion.

It is also highly important to distinguish between the inflammatory and scirrhous strictures of the intestinal tube. The former, as you have just been told, are confined, or nearly confined, to the upper and lower extremities of the tube, to the commencement of the œsophagus, and the termination of the rectum. In the œsophagus they are of so very rare occurrence that when stricture is situated in any part of that tube the chances are greatly in favour of its being malignant. It is out of the reach of the finger; and I cannot tell any symptoms that would, with certainty, enable us to decide that the disease is of simple nature. In the lower part of the rectum, the disease being within reach of the finger, is more readily diagnosed. Both simple and malignant strictures usually begin about the upper edge of the internal sphincter; and difficulty of defecation, with uneasiness about the parts, especially about the sacrum, are the prominent symptoms in both. The former are most common in young women—so far as my experience goes, in young women who have been the subjects of syphilis. They are attended with muco-purulent discharge, and frequently accompanied by abscesses, induration, or other signs of inflammation about the external parts and the adjacent mucous membrane. The finger finds the stricture, which is often very tight and sharp, to consist in an induration and contraction of the mucous membrane itself, and of the submucous cellular tissue. The stricture dependent upon scirrhous disease is most frequently met with in men who are above forty; is attended with frequent desire to go to stool, and with discharges of blood. There is nothing abnormal in the external parts or in the adjacent mucous membrane. The finger discovers a hard mass, of greater or less size, encircling the bowel and narrowing its calibre; and the mucous membrane may be traced unaltered through the centre of the mass, being puckered into longitudinal folds by the contraction that has taken place on its exterior. The mass just mentioned has close connections with the surrounding parts, rendering it, to a greater or less extent, immoveable. It is a point worth remembering, and which you will find as a general rule to be correct, that strictures depending upon inflammation are caused by induration and contraction of the *mucous membrane* and *submucous tissue;* whereas, the scirrhous stricture consists in disease and contraction of the *muscular coat*, the mucous and submucous layers being in the first instance intact. True, they become involved after a time, and cancer may even commence in them; but it does not then produce so much narrowing of the bowel.

Scirrhus is found to affect most frequently those who are in the decline of life, females about the period of the cessation of the catamenia, and persons whose nutritive energies have been lowered by fatigue, anxiety, or other depressing influence. It may appear, however, in much younger persons, and has even been observed in the fœtus in a few instances. It affects, so far as I know, individuals of all classes and all temperaments in an equal degree; the light and the dark, the fat and the lean, the plethoric and the anæmic, being alike subject to its ravages, or nearly so. Perhaps persons who are pale, thin, and of dark complexion, are somewhat more predisposed to it than others; but I am not sure of this. Very few organs and tissues are free from its invasions. It is most frequently met with in the mammary gland and the os uteri. It rarely commences in any other part of the uterus but the os. I have examined many patients, before and after death, and the specimens in several museums, without seeing a well-marked exception to this rule, which is of much practical importance; for if we find the os uteri healthy in a suspected case we may infer, with tolerable certainty, that the whole organ is free from scirrhus. In one case that proved fatal in the hospital the disease affected the middle part of the vagina, leaving the uterus free. It

sometimes commences in the absorbent glands. It does not usually affect the bones or voluntary muscles as a primary disease, though it often extends to them from other parts, or attacks them secondarily. In this specimen is a considerable scirrhous mass occupying the septum between the ventricles of the heart. The tumour projects into the left ventricle, raising one division of the mitral valve. The patient, (a woman,) from whom this was taken died of scirrhus of the œsophagus in the hospital. No suspicions of cardiac disease were entertained during her life.

The "encephaloid," or softer variety of cancer, differs from scirrhus, as has been already said, chiefly in the greater proportion which the cancer-cells and nuclei bear to the fibrous element. These cells appear to be the most active agents in the morbid structure; and it is doubtless in consequence of the large number of them contained in it that encephaloid cancer is so rapid in its progress, as compared with scirrhus. It is also owing probably to the active reproductive properties of these cells that encephaloid tumours attain so great size and are so vascular; the vessels in the adjacent parts being enlarged in a proportionate manner.

The appearances presented by the encephaloid structure vary a good deal in different cases, and in different stages of its progress. Under all conditions it is soft and pulpy, and, when covered by other tissues, it communicates to the finger a sense of elasticity very likely to be mistaken for fluctuation. It may easily be broken down by a probe or by the finger. Commonly it has, when in an early stage, a pale, gelatinous appearance, with more or less of a cream colour, and a shade of pink. Diffused through it at various parts, are probably spots or patches of an opaque yellow colour; these spots are blended with the rest of its substance, at least they are not separated from it by a very well-defined line. Frequently the whole mass has a mere dull, opaque-white colour, resembling not a little the white substance of the brain; and an abundance of thick, creamy fluid oozes from the whole of its cut surface, if slight pressure be made. This fluid often constitutes a large proportion of the substance of the tumour, and escapes from its surface if it be soaked in water for a time, leaving merely a fine reticulated structure, composed of delicate filamentous threads. The appearance so produced you may often see in the moist specimens of soft cancer preserved in museums.

So soft and delicate is the structure of an encephaloid tumour, that the vessels dispersed through it, (which are commonly considerable both in number and size, and, owing to the rapidity of their growth, are not furnished with very stout walls, or great contractile power, resembling much the vessels in granulations), are very liable to give way. Hence the substance of the tumour is often sprinkled with small bloody extravasations; or blood may be infiltrated into its structure, giving it a deep crimson or red colour; and various shades of pink, saffron, and orange will result from changes in the blood thus extravasated. Now and then the effusion of blood takes place in such large quantities and with such force, that the substance of the tumour becomes almost entirely broken down; or cutting into it you find it to consist of a sac filled with large coagula, with perhaps scarcely sufficient of the proper structure remaining here and there to enable you to decide the real nature of the disease. This tumour, for instance, connected with the femur, is composed of a large hemispherical sac, which was full of black fluid, and softly clotted blood; we might have been at a loss to account for such a circumstance had there not been on one side of the sac a mass of firm, white, medullary matter. The large tumour of the fore-arm here shown, is a still more remarkable instance of the same kind. When recent it was found to consist of a large sac filled with coaugulated blood, of which the greater part looked as if it had been recently effused and coagulated, though some of it near the circumference had probably been longer in the sac. The walls of the sac were lined by a thin layer of soft reddish substance, like lymph, which was without difficulty scraped off; and when it had been removed they were seen to be composed of the adjacent muscular fibres, tendons, and other tissues, stretched, but in a perfectly healthy state. In a few places we found, upon careful examination, on the interior of the sac, small button-shaped masses, which were composed of blood, intermixed with a soft white substance; and at the back of the tumour was a small mass presenting the ordinary appearance of medullary substance without any intermixture of blood. These would all have been overlooked had we not spent some time in examining and dissecting the tumour. The radial and ulnar vessels passed over the sac in close contact with it; they were quite healthy. The limb was removed by amputation from a man, aged 30, who said that a swelling had formed above the wrist three years previously, in consequence of a sprain; for two years it remained nearly stationary; in the last year it had increased very quickly and been attended with a good deal of pain. The forced flexion of the fingers, caused by the stretching of the flexor muscles, pressed the nails against the lower part of the tumour, and had caused a small ulcerated opening into the sac, through which large quantities of blood had escaped. The tumour measured twenty-two inches in circumference. The man recovered from the operation, and was in good health a year and half afterwards.

Sometimes we find the tumour composed of cysts of various sizes containing serum, or turbid bloody fluid, or coagula, or softened medullary substance, mixed with coagula. The walls of the cysts are thick, and together with the interspaces between them, are infiltrated with medullary substance. The cystic variety and medullary disease is most frequent in the ovary; but it occurs also in the interior of the bones, and occasionally in other parts of the body.

An interesting and remarkable circumstance to which I have already directed your attention when speaking of enchondromatous tumours, is the occasional presence of nodules of cartilage in the midst of encephaloid growths. They are composed of structure resembling genuine fœtal cartilage; and they are imbedded, sometimes in the medullary mass itself, at others in fibrous

tissue which separates it from the medullary substance. This combination of cartilage with encephaloid structure is met with most frequently in the testicle. It is not quite certain in cases of this kind whether the encephaloid growth is engrafted upon one of a cartilaginous nature; or whether, on the other hand, the encephaloid disease has the priority, and some of its structures undergo a cartilaginous transformation; or, lastly, whether the two diseases—the encephaloid and the enchondromatous—originate and proceed together.

What has been already said of the mode of growth of cancerous tumours and their influence upon the surrounding tissues, applies to the encephaloid variety, no less than to the others. The new material seems to be infiltrated among, or blended with, the natural structures, of which some are hypertrophied, and others disappear or are transformed. The tumour spreads by invading, assimilating, and destroying the surrounding parts, and is, therefore, as a general rule, devoid of any capsule. Sometimes, however, the rate of growth of the interior of the mass exceeds considerably the rate at which it involves the contiguous structures; in such case it attains a great size, displaces the adjacent parts, stretches and compresses the cellular tissue, and forms a capsule for itself after the manner of a simple tumour. Thus it is in consequence of the greater rapidity of their growth that encephaloid tumours are more frequently capsulated than scirrhous. The presence of a capsule investing and isolating them from surrounding parts of course greatly facilitates their removal by operation.

Probably nothing has so great an influence in restraining the growth of these tumours as pressure. Its effect in this way may be estimated, by observing the rapidity with which the morbid product sprouts forth when the skin and other tissues which had covered the tumour give way, and are destroyed by ulceration. It grows very luxuriantly at the exposed part, and soon forms a considerable mass, like a fungus, overhanging the surrounding skin. The occasional manifestation in this way of that property of rapid growth which forms an important feature in the encephaloid group of cancer, has caused the term "fungous" or "fungoid" to be applied to it in all its stages. The word "hæmatodes" ("fungus hæmatodes") superadded by Hey and other surgeons, is expressive of the liability of these fungous growths to bleed frequently, and freely.

Soft cancer is more frequently found at an early period of life than scirrhus, being met with in the fœtus, and at every period after birth. Children with dark-brown hair, and florid rosy complexion, are not liable to it; but I have seen it attack the pale, light-haired, and leuco-phlegmatic adults, and old people are by no means exempt from its visitations, though the chance of being afflicted by it decreases as they advance in years. Like scirrhus, it affects a great variety of organs, but is most frequently found in those parts which are least subject to scirrhus, viz., the testicle, the ovary, the eye, and the fundus of the uterus. Sometimes it begins at the os uteri. It often attacks the exterior of the bones, more particularly the superior maxillary bones, the pelvis, and the femur. Under such circumstances the medullary matter is infiltrated between the bone and the fibres of the periosteum, the latter becoming enlarged, thickened, and ossified, from the spirules, layers, and masses of new osseous matter which are so commonly found shooting from the bone into the substance of the tumour. Enough has been said upon this in a former lecture, and I would now only remind you of the remarks that were then made, and exhibit to you this specimen which has been lately obtained; it was taken from a lad, aged 13, who had for five years complained of aching pain about the right thigh. When we first saw him, two years before death, there was a hard swelling around, and evidently connected with, the upper part of the shaft of the femur. It felt like a mere thickening of the bone, but was larger than a swelling from that cause usually becomes in so young a person; the muscles moved freely over it, and we supposed it to be some tumour growing from the femur. Such tumours at that time of life, in that situation, being for the most part of encephaloid character, we gave an unfavourable opinion, notwithstanding the extreme hardness of the mass, which might have been thought incompatible with the existence of soft cancer. The disease progressed slowly for some time, but in the last year its advances were more rapid, and the tumour became less hard, and assumed more the appearance of an encephaloid growth. You see that the tumour is composed of two distinct structures—a central solid mass of very dense heavy bone, and a thick circumferential layer of pale, soft, medullary substance. The bony mass is two or three times as thick as the femur, whose place it occupies, and it presents no trace of medullary cavity or other rudiments of the femur. A magnifying glass shows it to consist of a dense network of thick osseous fibres, including very small areolæ, and a fine section exhibits, under the microscope, tolerably distinct haversian canals and corpuscles, somewhat less regular, but sufficiently resembling those of true bone. The encephaloid substance affords numberless large compound cancer-cells. The two structures are in close contact, and united by continuity of tissue, though their line of junction is well defined. The lower part of the shaft of the femur can be seen gradually expanding into the tumour, and surrounded by medullary and bony matter, the two structures being here blended together. It is the most remarkable instance of the tendency to hypertrophy or hyperostosis, as it is called, in bones affected with encephaloid disease that I have met with. A few years ago the term "osteo-sarcoma" used to be generally applied to tumours of this kind. Perhaps "osteo-encephaloma" would be better, as conveying a more accurate idea of the real nature of the disease. Moreover, the word "sarcoma" being of very indefinite signification, is, in the present day, employed by few accurate pathologists. Most, if not all, the tumours described by Müller under the term "osteoid," are, I believe, examples of this kind, or, more rarely, of simple tumours in course of ossification. Sometimes, as in this specimen of encephaloid disease of the femur, the medullary substance is infiltrated into the cancellous

tissue of the bone, and between the layers which form its walls, rending the latter asunder, and expanding them to considerable thickness. Here, too, the cancellous tissue at one part of the femur is solid, very hard, "ivory-like," presenting precisely the appearance described to belong to osteoids. When the disease originates in the cancellous texture of the interior of the bones, it is generally in the articular extremities, rarely in the medullary tubes of their shafts; and it is remarkable how long the articular cartilages resist the ravages of the disease, and preserve the immunity of the joint long after the adjacent part of the bone has been entirely destroyed.

Soft cancer sometimes attacks the muscles primarily, and now and then it makes its appearance in the skin. When it does so the tissue of the cutis and of the subcutaneous areolar membrane, become infiltrated with the morbid product, and the surface of the skin may be raised into little rounded tumours, somewhat resembling those occurring in molluscum. Hence the term "mollusciform" cancer has been applied to the disease presenting this form.

The difficulties in the diagnosis of soft cancer are practically very many and very great. I can but warn you of them, for experience and caution only can prevent your being occasionally deceived. Probably I am correct in saying that no one other disease has been the source of so many capital blunders in the practice of surgery. In the first place, the age of the patient, his healthy florid complexion, and well-nourished frame, often throw us off our guard, and prevent the suspicion of so desperate a disease. Secondly, the elasticity of the tumour, which the nicest touch may be unable to discriminate from fluctuation, together with its quick formation, the vascularity, tenderness, and perhaps œdema of the superficial tissues, suggest the probability of an abscess; but blood instead of pus follows the incision, and a probe or the finger passes into a soft brain-like mass, small portions of which probably escape, and present the general and microscopical characters of medullary cancer. The same features that cause encephaloid tumour to be mistaken for an abscess, or some of them, are likely to cause it to be mistaken for a cyst or a fatty growth. I have already mentioned an instance of this kind, in which an operation, commenced for the purpose of removing a fatty tumour, was suspended in consequence of the hæmorrhage that ensued, and the discovery that the disease was of malignant nature. Thirdly, these encephaloid tumours, owing to the number and size of the vessels distributed to them, are occasionally found to be attended with pulsation, and have, for that reason, been, in several instances, mistaken for aneurism, and treated by ligature of the neighbouring large vessels. Thus the femoral artery has been taken for a pulsating tumour on the inside of the thigh, the internal iliac for a pulsating tumour of the buttock, and the common iliac for a pulsating tumour of the iliac region; and in each of these cases the disease proved to be malignant, In all, doubtless, the utmost attention was given to ensure a correct diagnosis; and in each we may unhesitatingly believe that the mistake depended upon the complexity of the symptoms rather than upon any want of tact or caution on the part of the surgeons. There are many other sources of fallacy connected with the diagnosis of soft cancer. I have in two instances known amputation performed for malignant disease of the internal condyle of the femur, by surgeons of eminence, under the impression that the affection was only the common synovial disease of the knee-joint.

ON THE PROGRESS OF PUBLIC HYGIÈNE AND SANITARY LEGISLATION IN ENGLAND,

AND THE ADVANTAGES TO BE DERIVED FROM THEIR FURTHER EXTENSION.*

By J. INGHAM IKIN, Esq.,

Fellow of the Royal College of Surgeons of England, and Lecturer on Anatomy and Physiology in the Leeds School of Medicine, etc.

Read before the Leeds Philosophical Society, March, 1851.

With regard to the progress of military hygiène I might also say a good deal; but here also I must forbear; and not wishing to be invidious, will only allude to a few names in connexion with this honorable profession—this efficient upholder of our country's glory—this best preserver of peace, and check upon the tyranny of numbers. By congregating men together in armies disease has frequently broken out with great virulence. But the cause of this has almost always been from some gross inattention or ignorance of the principles of hygiène. Ignorance of the nature of the soil on which an army is encamping—of the products of the country—of the diseases of the climate—the condition and nature of the food, have too often been deplorably exhibited in the history of the campaigns of our army. But military hygiène is no longer disregarded by the medical officer or the general in command; and in the last war the army, under that efficient and indefatigable public servant—that honor to our profession, Sir James McGrigor, was a perfect model with respect to attention to preserving the health of the soldier. Choice of quarters—arrangement of uniform—security of, and attention to, the sick and wounded—attention to diet and the general physical condition and comfort of the soldier; nothing of any moment escaped the eagle eye of this experienced surgeon; and his immortal General, Wellington, knew well how to appreciate the services of such a man.

When Sir James McGrigor (*vide Lancet's* account)† was appointed Director-General of the medical department of the army, he found it imperfect, the same as Sir Wm. Burnett had done the navy; no professional records of the state of health of the army, or its diseases, or their treatment, existing. No records, except those of a fiscal

* Continued from page 514.

† See Biographical Sketch of Sir James McGrigor, in the *Lancet*, one of the series now publishing.

nature relating to the expenses of the medical department and sick charges, had been made, or even required by the regulations of the service, from medical officers. He immediately set about reforming the entire management of his office. He issued from time to time orders for returns respecting sickness and treatment from the medical officers of all the regiments in the service. He, for the first time, adopted a nomenclature of disease, according to which medical officers had to make their returns; a point which introduced great uniformity into medical reports. At first these reports were ordered every six months. It required the greatest energy and incessant labour to bring this plan into successful operation, neither were spared by this indefatigable public officer; as soon as he assumed the duties of Director-General he devoted his whole energies and labour to the well-being and hygiènic improvement of the service; rising early at five every morning, and constantly working till ten at night, his confidential correspondence being carried on to a great extent by himself. In this way the army medical department, which had been a mere office, became an important department of the public service. As a department it may be said to have been created by Sir James. After some time it was found that an annual report from each regiment was sufficient; and this has been continued with perfect regularity up to the present time. There are, as the results, now at the Army Medical Board Office, in St. James's Place, upwards of 303 returns, well classed, labelled, and encased, containing a mass of invaluable information respecting the health and general condition of troops in this country and abroad. These records must contain a mine of rich stores, having a most extended bearing on medical and sanitary sciences. The army and the State owe the splendid pathological museum, as well as the libraries at Chatham, to the indefatigable exertions of Sir James McGrigor. The elaborate statistical reports of the army and navy of the empire, which Colonel Tullock, Drs. Wilson, Marshall, and others, have published, demonstrate the improved condition of the public services, and will ever be ranked amongst the most valuable documents in the department of statistical medicine. Mr. Jackson's services have also been very great.

It may be added, in justice to others, that Sir James Grant was chief of the medical department of the army in Belgium in 1815. Mr. Gunning was chief medical officer on the field of Waterloo. Mr. Guthrie is one of our best authorities on the effects and treatment of gun-shot wounds; Mr. Franklin was chief of the medical department of the Queen's troops in India during the late war; Dr. French was chief medical officer of the army during the latter part of the war in China; Dr. Hume was the personal attendant of the Duke during the Peninsular war, and performed other important duties; and, lastly, the present Professor of Military Surgery in the University of Edinburgh, Sir George Ballinghall, deserves great praise, not only for his valuable lectures and services in this department, but for his zeal and anxiety in endeavouring to persuade the Government to establish military professorships in London and Dublin.

Whilst speaking of the progress of hygiènic matters in connection with the State, I may here allude to the investigations and labours of the first early promoters of the Factory Bill; for undoubtedly the passing of this Act has been of great moment in a sanitary point of view. The protecting of the lives and health of the young had become a matter of necessity, not only from the avarice of masters, but from the cruelty and neglect of parents. The political promoters and agitators for the promotion of factory legislation, though often led astray by their zeal and enthusiasm, deserve the gratitude of their country; and, in the progress of this, to us, (in this part of the country,) exciting question, the aid, co-operation, and testimony of the members of the medical profession tended more than any other influence to compel the interference of the Legislature. In this town many of my brethren took an active and successful part in this, (at that time,) fiercely contested question. Speaking of local efforts and exertions in this and other branches of my subject, I must not omit the name of Thackeray, whose treatise and inquiry on the comparative healthiness of different industrial manufacturing occupations and their effects, is well known to medical men, and was duly appreciated by them, as well as the public generally. Mr. Thackeray's industry, zeal, and talent, were sufficiently proved by this work; and I speak not only my own sentiments, and that from personal acquaintance, but that of others as well, when I say that Leeds suffered a great loss in his premature death. He laboured hard and successfully in what was then almost a new department of medical science; and he was an early and successful promoter of public hygiène, then in its infancy. I must also, in bare justice, couple his name with the earliest founders of provincial medical schools, and commend him as a most zealous promoter and teacher of anatomical science; indeed the profession and public of Leeds owe him much, for it was he who first gave a public course of anatomical lectures in this place; and his exertions ultimately gave origin to the more effective organization of the Leeds Medical School, which has now been successfully, but unostentatiously, carried on for twenty years, as the career of many of its pupils shew. And I need not say that the promotion of a sound and extended course of medical education has a very important bearing upon the extension of hygiène; and that efficient medical men are requisite to advise upon, and carry out, sanitary measures; and officers of health should be something more than able policemen or mere inspectors of nuisances. Besides the passing of a Factory Bill, another useful hygiènic regulation was, the rendering it compulsatory for all owners of ships having a crew of, or carrying, fifty persons on board, to appoint a surgeon to take charge of them. The health and condition of the poor emigrants are thus much better attended to; indeed, we now hear of lords and ladies superintending the fitting up and arrangement of emigrant ships. And as for prisoners in gaols—felons and murderers—they can now, from our new system of prison inspection and regulation, get as good medical superintendence, and much

more regular attendance, than any honest mechanic in the land; and certainly have smarter dwellings, cleaner apartments, and better provisions, than thousands of the deserving poor. But this, by the way, is one of the crotchets and absurdities of the day:—reforming prisoners by keeping them idle in fine castles—improving so zealously the receptacles for crime before attending to the sad condition, both moral and physical, of too many of the poor in all our large towns.

Another Act of Parliament of immense importance, and having an intimate connexion with public hygiène, was the passing of the Bill for registration of births and deaths; also that for the promotion of vaccination, thus giving the public an opportunity of gratuitous vaccination. The reports of the Registrar-General might alone afford ample materials for a series of interesting papers. The able manner in which these reports are written deservedly obtain the most general commendation, both in and out of the profession. The facts they contain and state so concisely are most instructive and useful; and, in a hygiènic point of view, the Registrar's reports are not to be equalled by any other public document.

The classification of diseases, the accuracy of the statistics, the admirable comments and practical deductions are, from their simplicity and correctness, wonderful steps in advance of what such reports would have been even twenty years ago; and had time permitted, I might have made use of these reports in elucidation of my subject in the most striking manner, and with great advantage to myself and instruction to my audience. Suffice it to say, on the present occasion, the Registrar-General's statistics and facts abundantly prove how attention to the ordinary precautionary means at our disposal for promoting the health of the community conduces to health and longevity; and how, on the other hand, a neglect of the laws of hygiène generates fever, and epidemics, and increases mortality. In these reports we find how the poor, the intemperate, and the unclean, are much more exposed to contamination and contract diseases, which the more affluent, cleanly, and temperate escape. They also show to the most sceptical, and prove over and over again the fact, which cannot be too often repeated, that adequate sewerage, along with an abundant supply of water, cleanliness, whitewashing, ventilation, removal of the source of malaria, and nuisances of all kinds, are the best and most efficient measures for promoting the health and comfort of the community. The queston of expense as to carrying out these measures adequately in all large towns, is quite of secondary importance, as the good results to be derived from them will soon amply repay the outlay, be that what it may. Another recent public act of hygiène, and one deserving of praise, is the Parliamentary inquiry into the cause of accidents in mines, and the very able and voluminous reports which have emanated from such inquiry. These contain numerous useful suggestions for the prevention of accidents in mines, and the result has been the appointment of inspectors; for it has too often happened that many lives are lost in mines from carelessness in the working of them, as well as from causes scarcely capable of entire removal, under the most prudent management and careful superintendence, though modern art and science promise to work wonders even with fire-damp and choke-damp, as the recent successes in Scotland in staying the progress of an extensive subterranean fire abundantly testify.

To proceed, allow me here to state, that in treating this subject, I must be excused adopting any precise order, with regard to the dates of public measures bearing on this question, or of accurate and precise adjustment as to priority of original and individual claims, researches, and labours, for it is almost impossible to adopt a strictly consecutive arrangement in furnishing you with a comprehensive outline of the progress of public hyigène in England, or of according with strict justice, the merits due to its numerous class of indefatigable and praiseworthy promoters.* With regard to the writings during the last fifteen to twenty years, that have conduced most, in my mind, to promote and extend hygiène in general, I must name conspicuously those of Dr. Southwood Smith, the author of the well-written work, "The Philosophy of Health, or an Exposition of the Physical and Mental constitution of Man, with a view to the Promotion of Human Longevity and Happiness," and of Dr. Andrew Combe, the author of the deservedly appreciated work (except for his extreme views on phrenology) "The Principles of Physiology applied to the Preservation of Health, and the Improvement of Physical and Mental Cultivation." The name of Mr. Chadwick is connected with all our improvements of a sanitary kind, and he promises to do much more. Dr. Alexander Kilgour's work also, "On Private Hygiène," and "Treatise on the Ordinary Agents of Life,—On Food —Clothing — Climate — Habitations — Exercise, &c." The American writers, Dr. Caldwell, "On Physical Education;" and Dr. Dunglison, "On the Influence of Atmosphere and Locality, Change of Air, Corporeal and Intellectual Pursuits, &c." The useful and practical lectures of the philanthropic Dr. Hodgkin, "On the means of Promoting and Preserving Health," which he delivered at the Mechanic's Institution, in London, and which were published in a cheap form, probably at the suggestion of Lord (then Henry) Brougham, one of the most able advocates, not only for the education, but for the social improvement of the people. I must also name the late Dr. James Johnson's work "On the Economy of Health;" that of Herbert Mayo, "On the Philosphy of Living;" and the standard treatises of Drs. Paris and Pariera, "On Diet," as well as that of Dr. Robertson, and the numerous works on chemistry, especially organic chemistry, such as the well-known important one of Liebig. Dr. Black's Lectures on Hygiène;† and those given by professors and teachers where this branch of medical science is incorporated

* If whilst alluding prominently to some writers, I overlook the labours of others, I must be excused for the omission, as this paper was somewhat hastily prepared, and with no view at the time of meeting the eye of the public.

† Published in the *Provincial Medical and Surgical Journal.*

amongst the other courses of lectures, have all along tended, with the works named, to give an impetus to this study, and are amongst the earliest and best writers upon it that I can call to mind. But in connexion with them, and in a great measure stimulating and encouraging the labours of such men, I must here include and notice the unceasing and eminent services of the *British and Foreign Medical Review*," when edited by Drs. Forbes and Conolly, as well as since it changed its editorship. The early numbers of this *Review*, by its series of able articles on hygiène, and the reviews of such works as those I have just enumerated, did more to call the attention of the Government, the public, as well as the profession, than almost any other journal or publication, prior to the issuing of the Report of the Health of Towns' Commission, and the more recent voluminous Parliamentary Reports on the sanitary condition of the people.

To the original *British and Foreign Medical Review*, and the *British and Foreign Medico-Chirurgical Review*, I am much indebted, for they have been of great use to me in preparing this paper, and my interest in the subject, as I shall have to state directly, is owing to the perusal of its very earliest numbers; and this *Review*, under its new editorship and title, continues ably to discuss and promote the cause of hygiène. Whilst alluding to the press, and to medical periodicals, it would be an act of injustice to overlook the untiring exertions, zeal, and talent of the *Lancet*, and its independent Editor; its pages have ever been open to the cause of hygiène, and have long and ably tended to diffuse hygiènic knowledge, and to promote the welfare of the poor, as well as to advocate the just rights and claims of the medical profession. The passing of the "Medical Witnesses Bill" is due to Mr. Wakley, and his very office as Coroner has often led him to investigate matters of hygiène, and those for the protection of the lives, health, and comfort of the people. At present the labours of the *Lancet* are beyond all praise, in the promoting of the "Analytical Sanitary Commission," and publishing its consequent disclosures; these results I shall have, however, to allude to again at the end of this paper, as they are amongst those of the most recent date, and the inquiries are still going on. The pages of the *Medical Gazette*, the *Provincial Medical and Surgical Journal*, and the *Medical Times*, have also ever been open to the discussion and furtherance of this cause, and many valuable lectures and papers on the subject have appeared in them (as at one time it was thought an almost exclusively medical subject,) and continue to do so, especially the reports on the prevalent diseases and meteorological condition of particular towns and districts. The *Edinburgh Review*, the *Quarterly Review*, and others, have aided the cause, and often published most telling articles, either directly or indirectly connected with the sanitary improvement of the masses; for, to the credit of the press be it spoken, this cause is not now exclusively confined to the medical portion of it, but the leading journals of London, especially the *Times*, (which is ever on the *qui vive* to see how the wind blows, and has the talent of foreseeing how to steer its course accordingly,) is a mighty advocate for sanitary reform and extension, as well as a just appreciator of the labours of medical men, and an able defender of their rights and interests. Indeed the best portion of the press, both metropolitan and provincial, now see the propriety of urging on improvements of a hygiènic nature, seeing that it will best promote to the health, cleanliness, and comfort, of all classes. Our own press in Leeds has certainly done its duty, and public attention is now becoming more and more directed to such beneficial and practical questions as the one we are discussing.

It was from reading a capital article in almost the earliest number of the *British and Foreign Medical Review*, (the second number of it,) that induced me, fourteen years ago, (and probably it might have had the same effect on others,) to add one's mite in the promotion of the cause of hygiène, and in the promulgation of sound hygiènic principles, and to aid in furnishing facts and information to the party most interested—the public at large. The perusal of the paragraph I am about to quote, was the cause of my preparing a somewhat extended course of "Lectures on Public Hygiène," which were first given in the neighbouring town of Halifax, for the benefit of a public institution, and published in the newspapers, and afterwards delivered in Leeds above thirteen years ago. This, I may be allowed to state, without opening myself to the charge of presumption or egotism, in order to show the effect produced on one's mind, and the practical effect of the suggestion herein contained, and certainly it is a satisfaction to feel that one's earliest public efforts were in such a useful direction, and that the subject was taken up before it was even popular, much less fashionable.

In 1836 the *British and Foreign Medical Review* thus wrote:—"If we could flatter ourselves that our recommendation would be effectual with the numerous physicians and surgeons who may peruse these pages, we would earnestly impress upon them the duty of assisting in this great, humane, and we may truly say, *patriotic* labour, of instructing the poor how to be healthy, and thus to facilitate their being virtuous, prosperous, and contented. They alone possess the knowledge which would be to them health and life. This great service would not be less worthy of them than those more laborious services which they now give in hospitals and dispensaries to many who *ought not* to require the aid of charity. The truest, noblest, and most effective charity, is that which teaches the poor to *depend* on themselves, to avoid the causes of disease, and by preserving their health under all ordinary circumstances to secure the means of providing for such visitations as cure cannot avert. From the works already reviewed, any medical man may, with little trouble, derive materials for lectures to the poorer classes of his town's-people, and his local experience will always furnish him with illustrations. The public will be found grateful for such exertions." They add in another part:—"Any reader versed in the history of this country for the last forty years, must be able to

call to mind more than one occasion in which a knowledge of the laws of hygiène might have prevented great public loss, and such loss would have been much greater, and more frequent, if the intelligence and research of the medical officers of the army and navy had not led to the discovery of many of these laws by observation. There are melancholy cases of disease against which no prudence would have been effectual, but their number is insignificant compared with that of those that spring from ignorance and neglect. By removing this ignorance, the instances of neglect will be made more rare; and nothing is more certain than that, by increasing the general health of mankind, the general amiability and virtue, and thus in every way the general happiness of human beings is increased at the same time."

The works alluded to, and the article from which I have just given the above quotation, were published in 1835 and 1836. Good results gradually became apparent, especially from the labours, perseverance, and talent of Dr. Southwood Smith, Dr. Arnott, Dr. Kay, (now Dr. Kay Shuttleworth,) and I must in justice add, the indefatigable industry, comprehensive mind, and practical tact of Mr. Chadwick, then Secretary and a most active member of the Poor-Law Commission. Without touching upon the debatable topic (foreign, in fact, to this place) of the merits of the whole regulation and policy of Poor-Law Commissioners, all parties will admit that the inquiries, reports, and suggestions of this body have been of great utility, and deservedly merit a conspicuous place in the history of the recent impetus given to public hygiène. In the fourth annual report of the Poor-Law Commissioners, presented in May, 1838 (*vide British and Foreign Review* for April 1845) from which I now quote, there were two supplementary reports, one by Dr. Arnott and Dr. Kay, on the prevalence of certain physical causes of fever in the metropolis, which might be removed by proper sanitary measures; the other by Dr. Southwood Smith, on the condition of the poor in Bethnal Green and Whitechapel, and exemplified some of the physical causes of sickness and mortality to which the poor are peculiarly exposed. In the *fifth* annual report of the Commissioners there is a report from Dr. Smith on the prevalence of fever in twenty metropolitan Unions during the year ending March, 1838. In August, 1839, the Poor-Law Commissioners received instructions from the Secretary of State for the Home Department to inquire to what extent the causes of diseases, mentioned in the reports just named, prevailed amongst the labouring classes in England and Wales. They were thus constituted a Board of Health, not for administration, but for inquiry; and, consequently, in November following the whole administrative machinery of the Commissioners throughout England and Wales, was put in motion for the purposes specified. In November, 1840, instructions were issued from the Home Office to the effect that the inquiry should be extended to Scotland. These extensive and useful inquiries, so ably conducted, terminated in the presentation to Parliament of three volumes of Reports, two volumes of *Local Reports* on the sanitary condition of the labouring population of Great Britain, the first volume on England and Wales, the second on Scotland. The *General Report*, by Mr. Chadwick, is a condensation of these Local Reports, and has been described (see *British and Foreign Medical Review)* "as constituting the most valuable and complete treatise on certain departments of medical police ever published, either in this or any other country." As you have access to the work it is quite unnecessary for me to analyse it; but it would be an omission indeed not briefly to allude to its contents. Suffice it to say, Mr. Chadwick demonstrated the evils which were the subject of inquiry in a manner so satisfactory as to cause the prosecution of further inquiries, and finally to State legislative interference.

The comparative unhealthiness of the large manufacturing districts as compared with the purely rural districts had been shown before; and the comparative changes of life in different classes of the community had been accurately ascertained and pointed out; but the satisfactory proof and tracing of cause and effect is shown in cases where the neglect of drainage, cleanliness, and supply of water was found to be universally followed by increased mortality, the generation of fever, and spread of cholera. This consequence was now so prominently displayed as to alarm our legislators, as well as convince the public of the necessity of adopting measures to prevent the increase of such mortality. In our town a valuable inquiry and report of the Town Council on these matters was made; and Mr. Baker, now Sub-inspector of Factories for this district, was very active and zealous in this inquiry, and drew up a map, differently shaded, showing how undrained and dirty portions of the town were more unhealthy than any other part. This map is not novel in its plan,* but was not less useful on that account. He was also an able witness before Parliamentary Committees. Many other members of the Council took an active part in this inquiry. Mr. Chadwick, under the head of "Pecuniary burdens created by the neglect of sanitary measures" gives most convincing proofs and figures of the costliness of inattention to public hygiène, and the then apathy of the Legislature on this matter. He also adduces a vast variety of evidence, showing the effects of preventive measures in raising the standard of health and the chances of life. The comparative inability of poor workmen to improve their own condition, and the necessity of external aid for obtaining this improvement is satisfactorily exhibited and demonstrated beyond doubt in this report. The great influence that a kind employer has, not only over the opinions, but the health and general condition of his workpeople, is well shown and proved to be very great. He alludes to the mills of Catrine in Ayrshire, to the effect of comfortable cottages and dwellings, and the modes of building them, to the effects of public walks and gardens on the health and morals of the

* *Vide* Bulwer's "France; the State of Crime in the different Departments," &c. Illustrated by a shaded map.—I.

lower classes, to the patriotic gift of the Arboretum at Derby, by Mr. Strutt, on which a walk of two miles is contrived in eleven acres, and one thousand specimens of shrubs and plants are displayed. I may also add, the great improvement in our own mills, and the apportioning of allotment gardens deserve special mention here; the attention of our Marshalls, Gotts, and others, to the well-being of their work-people is universally admitted. The construction and arrangement of Messrs. Marshall's huge mill is considered one of the sights of the age. After all, we are forced to admit that much remains to be done, in the promotion of the sanitary condition of the working classes, and that riches and station have their duties to perform, as well as their influence to exercise. The poor man works for, and adds to, the wealth of the great capitalist, and he is fairly entitled to assistance as well as advice, by the institution of public measures for his special benefit. I allude now in particular to the interference by local and general Acts of Parliament, compelling the adoption of adequate drainage, the building of a better class of cottages, dwellings and lodging houses for the working classes, the establishment of public baths and washhouses, public walks and parks, and the encouragement of healthy manly pastimes and exercises, and along with them, those institutions for mental improvement, now found to work so admirably—Mechanics' Institutions—to which ere long we shall see added free museums, public halls, and cheap reading rooms. All these means will tend to promote the cause of public hygiène. To return for a moment to Mr. Chadwick: in another section of his able report, he discusses at length the state of the then existing laws for the protection of the public health, and shows their inadequacy to the wants of society, and with his usual skill and tact, makes out a case for legislative interference. Mr. C. is quite at home amongst drains and sewers, and dwells strongly upon the plan of rendering the refuse of towns available in a pecuniary point of view, though it was Mr. Smith, of Deanston, who first suggested the propriety of rendering such refuse profitable to the authorities of towns, by its sale for agricultural purposes. Mr. C. also has an essay on Boards of Health and Medical Police, and brings forward a plan of his own, which includes medical inspection not only for the poor, but for streets, houses, sewers, &c., also the supervision of surgeons under the Poor-Law, of recruits, factory children, prisons, workhouses, lunatic asylums, public schools, manufactories, and workshops of all kinds, as well as the supervision of mortuary registers, coroner's inquests, &c. The propriety of such general interference is questionable, as public opinion ought to be sufficient to prevent abuse and grievances in large establishments and public institutions, and the aid of the State should be called upon only when independent and voluntary exertions are unequal to the case. Indeed Mr. Chadwick's plans, reports, and legislation are generally overdrawn, so to speak; he thinks public boards have only to draw up a code of rules sufficient to meet any exigency, and that the carrying of them into practice will be sure to follow.* He errs grievously in this respect; his intentions are good, and his suggestive talent is wonderful, but his schemes are often found impracticable. Witness his recent rules defining the duties of the officers of health.* But I must now pass on to another important step in sanitary legislation; I allude to the appointment of a select committee by the House of Commons, to inquire into the evils arising from interments within large towns, and to the issuing of a Royal Commission for an inquiry into the *state of large towns and populous districts.*

[To be continued.]

CASE OF IDIOPATHIC GANGRENE OF THE FOOT.

By G. BOTTOMLEY, Esq, Croydon.

Read at the Nineteenth Anniversary Meeting, held at Brighton, August 13, 1851.

I was called, in consultation, to see William Mascall, aged 53, of Croydon, Surrey, on January 16th, 1851, a rather short, stoutly-built man, flabby and lymphatic in appearance. Complexion pale; habits have been somewhat irregular; has lived freely; seldom the worse for liquor, "but drinks little and often;" his usual beverage is porter, either alone or with gin in it; appetite never very good; has been the subject of dyspeptic symptoms more or less for some years. He is a master builder by occupation, and does a fair amount of manual labour himself.

He states that, on the 7th of December last, he was running down hill at the top of his speed, when he felt a sudden pain in the calf of his right leg, as "*though something had given way deep in.*" It was very severe at the time, and he had difficulty in walking home in consequence. As it persisted for a few days, and confined him to the house, he obtained medical advice, and used fomentations and lotions. There was no swelling or unnatural appearance of any kind. Gradually the pain subsided, although he has felt more or less at the same spot ever since, and this foot and leg have been so much colder than the other ever since this occurrence, as to occasion him to wrap it up in flannel at night, of his own accord. He had never noticed any decrease of temperature in it before. For the last three or four days the right foot has been exceedingly painful, rather red, and swollen, and the day before yesterday he first observed that the great toe had a greenish tint, and that there was a small black spot on that side of it which comes into contact with the adjoining toe. The whole toe became redder, and swelled at night, and the blackness had spread over nearly the whole of it. On the day previous to these appearances taking place, his medical attendant applied lotions, and four leeches, to relieve the pain.

Present condition.—The whole of the great toe is of a dark livid hue. The instep is redder than natural, the

* This code of rules was published in a recent number of the *Provincial Medical and Surgical Journal.*—I.

dark colour of the toe shading off imperceptibly into it, and it is painful when touched. Temperature of the right toe very sensibly lower than that of the left. There is some oozing of dark blood from the leech bites. On *close examination* no pulsation can be found in the popliteal artery, or below the space, and it is only by very strict attention that a few faint beats can be detected in the femoral; these appear to be intermitting. There is some tenderness, but by no means much, in the line of this vessel; its course is not distinct. Much thickening of indeterminate form and limit occupying the upper part of Scarpa's triangle. Pulse is 100, moderately full, soft, compressible; heart sounds natural; tongue coated with thick dirty fur; bowels open; spirits good.

In consultation on this case, removal of the limb by amputation was proposed. I objected, on the following grounds:—

1st. In the condition of the local circulation, whatever might be its cause, there was much reason to doubt whether the vascular energy would be sufficient to cope with the demand necessary for the maintenance of the reparative process in so large a wound as an amputation of the thigh must involve; and the want of ANY PULSATION in the popliteal, would of course preclude an operation lower down. Sloughing of the stump, if not secondary hæmorrhage, with their consequences, were certainly to be feared.

2nd. The condition of the patient's general health was unfavourable—the amount of vigour in the system was scarcely equal, perhaps, to ensure a favourable course of things—certainly insufficient to meet any unfavourable contingencies following the operation. This is of more importance than the age simply, which of itself could not in this case be considered a ground of objection.

3rd. There was no indication from nature as to the extent to which the process of mortification might extend; neither, at the same time, was there any rapid progress to be feared.

The result was, that any operative interference for the present was declined, and the patient was placed from this time under my care.

January 19th.—By diet, and small doses of blue pill, his digestive functions are improving. The blackness is slowly creeping over the instep, and inflamed lines of lymphatics have appeared, running up to the centre of the thigh. Pain is severe in the foot, especially when kept warm by local applications, as carded wool, in which it had been enveloped; and he finds ease in evaporating lotions, and moderate temperature. Ordered a mixture, containing quinine, morphia, and tincture of rhubarb, nutritious light food, and a moderate quantity of his accustomed stimulant.

February 1st.—During the last ten days his tongue has been gradually cleaning, and his powers increasing; the appetite good, and his diet has included plenty of good beef-tea, milk, &c. The local pains have been relieved, and sleep at night obtained, by the use of about two or three grains of opium in the twenty-four hours. The quinine has also been continued. The blackness has reached the ankle, and there is redness and œdema to the middle of the leg. Pulsations in the femoral are noted daily with care, and seem to vary; sometimes they can barely be distinguished, at others with more ease, but always much below the size and force of those of the corresponding artery of the other limb. There is no pain in the line of the artery.

8th.—Slowly improving in general condition. During the past week there has been a gradual failure in the pulsations of the femoral, so that now on the closest scrutiny not a single beat can be felt; neither in the direction of the external iliac beneath Poupart's ligament, nor in any part of the limb below. No extension of the livid colour, which seems disposed to stop just above the ankle. The sphacelated part becomes drier, and shrivelled. Continue opiates. Quinine replaced by decoction of cinchona and ammonia. An occasional blue pill when the bowels are costive.

15th.—Much the same in general health; the pulse has gradually risen to 100 and 108; there is now a well-marked line of demarcation above the ankle-joint, and a free discharge of pus and oily matter. Separation seems rapidly progressing through the soft parts.

March 15th.—During the past month the process of separation has been going on steadily; the tendo-Achillis has given way; there has been very little pain; discharge moderate, and healthy; health and strength as last report; treatment varied at times, but continued on the same principles. It is evident now that little more remains for division beside the bones of the leg, it is therefore proposed to divide these, with as little disturbance to the soft parts as possible, in the course of a few days.

24th.—Having given him chloroform, I removed the dead foot by dividing the ligaments of the ankle-joint, then cautiously separating the soft parts from the exposed tibia and fibula, the lower ends of which were evidently necrosed for one inch and a half or two inches. I detached about two inches of each bone by means of the saw and forceps, and brought small flaps into fair approximation over them with isinglass plaster. No vessel required tying, and very little blood was lost in the operation.

From this period he had scarcely a bad symptom; his appetite and condition improved rapidly, the wound chiefly healing by granulation, but forming a fair and serviceable stump for the adaptation of an artificial foot, which I propose that he should obtain when the part is sufficiently consolidated to bear one. In two months from the time of the removal of the extremity he was able to walk with the assistance of crutches, and overlook his men at work.

I have recently made a careful examination of the limb. There is no pulsation to be found in the line of the main trunks in any part of it, no distinct cord can be felt, but the same kind of thickening as before described, and a similar condition exists in the popliteal space. I can detect no difference in temperature between it and the sound limb. The patient stated, without any suggestion from me, that he could feel "a pulse beating behind at the top of his thigh when seated

in a chair," though I could discover none by palpitation there.

Some interesting speculations might be indulged, did time permit, as to the circumstances which led to the occurrence of gangrene in this case. What was the cause of the failure in the circulation? I am inclined to think that arterial degeneration had long previously been by degrees obliterating the main channels of vascular supply, and a low form of inflammatory action might also be set up in and around them. His sensations at the time of running down the hill, and subsequently, must be admitted to have arisen in connection with some lesion occurring there, possibly the rupture of a calcified vessel. A collateral circulation, however, is now performing its functions admirably, and affords an interesting example of nature's resources in this respect. His sensation of pulsation, when in the sitting posture, is so natural that it must be regarded as evidence as to the course by which the blood now reaches the extremity. I have only further to add, that the patient is at this moment enjoying as good health as he ever had in his life, although from a small exfoliation of dead bone from the tibia, not at present quite ready for his artificial foot.

ON THE

MANAGEMENT OF WOMEN AT, AND AFTER THE CESSATION OF, MENSTRUATION.*

By E. J. TILT, M.D.,

Senior-Physician to the Farringdon General Dispensary and Lying-in Charity, and to the Paddington Dispensary for Diseases of Women and Children

On Purgatives.

Amongst the vicarious diseases by which nature enables the system of women to right itself, diarrhœa is one of the most frequent; as it forms an immediate diverticulum for that periodic flow of fluid which has now outlived its utility; and as it is also the most convenient local depletion by which we can habitually relieve the system, the employment of purgatives at this stage of the menstrual function fully deserves the confidence which the profession has long accorded to the practice, and the sanction which Fothergill has given it in a well-known contribution to medical literature. The utility of purgatives has become so much a matter of popular, as well as of medical belief, that both patient and medical attendant too often confide in them alone, to the neglect of the other more important means I have already alluded to. This mode of treatment is one of nature's own suggesting, for it was found that diarrhœa occurred at cessation in the following number of instances:—

Diarrhœa existed in	12 per cent.
" was irregular in	8 "
" was regular, by coming on every month in	4 "

I might give numerous cases in proof of the utility of this occurrence, but I will merely state the following:—

* Concluded from page 404.

Case.—Catherine Mackey, aged fifty-three, tall, thin, with dark hair, grey eyes, and pallid complexion, was born in Ireland, but for the last thirty-five years has resided in London. She menstruated very abundantly at between fifteen and sixteen years of age, was regular from the first, and continued so for three or four days every three or four weeks, with so little suffering that "she never felt them come nor go." She married at thirty-three, miscarried three times, and bore five children, the last at forty-seven; and menstruation, which had been irregular a year previous to conception, never returned after that event. The patient was generally relaxed during the menstrual epochs. During her last pregnancy, and after her confinement, she frequently had three or four stools a day, without pain or loss of appetite, and since then diarrhœa has come on every three or four months, with intermittent flushes and drenching perspirations. For the last twelve months she has been relieved six or seven times a day, until lately, when she has only been so once in two days, and has ever since suffered from heat, and oppression at the pit of the stomach, from wind, nausea, and want of appetite, but her tongue is perfectly clean and healthy. I adopted the same treatment as in the previous cases; and when the action of the bowels became freer the patient got better.

By imitating nature to a certain extent, as in this instance, it is often in our power to cure the milder cases, and to prevent the return of the more serious diseases.

The utility of purgatives at cessation is further shown by the very intimate relation which I have proved to exist between the generative and intestinal canals. The following table, extracted from a paper already referred to,* embodies the results I have obtained.

State of the Bowels during Healthy Menstruation

	Number of Observations.		
Author's second list:—

" confined	45		
State of bowels unaltered	22		
			— 100

* On Catamenial Diarrhœa, by E. J. Tilt, *London Journal of Medicine* August, 1851.

"On adding together the author's two lists, and that of Dr. Butler Lane, four hundred and nine observations are obtained, out of which it would at first appear that some kind of intestinal disturbance during menstruation was only absent in sixty-four cases; but I consider this proportion to be smaller than what is really the case, from the fact of my not having been sufficiently explicit in my inquiries of the seventy-three women reported as having their bowels confined in my first list. If I had asked them whether the bowels were in their usual state or more confined than usual, I should probably have obtained results similar to those I subsequently found, and then it would appear that some kind of intestinal derangement may be expected during menstruation in about seventy-five per cent. of cases. Diarrhœa occurred at some time or other in one hundred and ninety-nine instances out of the four hundred and nine cases, so that this symptom may be expected in about fifty per cent. of cases. The frequency of constipation, for reasons already given, cannot be inferred from the author's first list, nor from Dr. Butler Lane's, which are not sufficiently explicit, and further inquiry is necessary before I can venture to assert that it is faithfully represented by my second list."

This shows most forcibly how much it is necessary for us to *know* before we are in a position *to inquire;* and I am the first to confess, that although obliged to attach some value to researches which, to my knowledge, have never before been conducted on so extensive a scale, the principal value I ascribe to them is their having prepared me for continuing the same inquiry more fruitfully hereafter.

Returning to my subject, I shall remind the reader that I have shown that the two contiguous mucous surfaces of the uterine and the intestinal canals react on each other, in the normal state, in such a manner that the process of menstruation deranges the intestinal secretions; while, on the other hand, it is notorious that diarrhœa deranges the menstrual discharge, bringing it on when it should not appear, and prolonging it beyond its proper time. These contiguous surfaces are relieved by the same vessels, and are animated by nerves either derived from the same ganglionic nervous pleuxuses, or from the same portion of the spinal cord; and when the uterine discharge is arrested, the nervous energy and the blood which used thereby to find vent of a necessity to the intestinal surface, for the veins of the uterus communicate immediately with the portal system. This cannot occur without determining various derangements, carelessly expressed under the terms biliousness, indigestion, flatulency, acidity, diarrhœa, and costiveness.

Dr. Butler Lane's observations on the coincidence of the derangement of the biliary secretions at the change of life coincide with my own experience.

Nothing can be more common than to find severe biliary derangement occurring at or about the period of menstrual secession; and, looking at the great physiological change which then takes place in connection with hepatic development, it is naturally to be expected. A woman will complain of being bilious—viz., there may be a bitter, oily taste in the mouth, a sensation of burning in the throat, frontal headache, nausea, and even vomiting, the urine high coloured, the bile abounding in the alvine dejections, and perhaps causing heat and a stinging sensation in the rectum, the tongue furred, a biliary tinge pervading the cutaneous surface, &c., &c. Such symptoms, or a modification thereof, often mark the great and important vicissitude which takes place in the female economy at the influential epoch in question, and the due appreciation of the symptoms made manifest, their ascription to the real source, and their judicious treatment, medicinal and dietetic, are of the highest consequence to the future welfare of the patient. I suspect that a great majority of those distressing maladies to which the uterus and its appendages become liable in life, might be traced in their origin to neglect and maltreatment at the critical period."

Such a state, in which a cursory dose of calomel, or a pill and draught, are often beneficial, shows the utility to be derived from the systematic use of purgatives at the period of cessation; but this is no reason for throwing aside other remedies, and neglecting the observance of the wholesome sanitary measures I have carefully inculcated.

How then must purgatives be administered?

At that truly critical period of the lifetime of woman, comprised between that when the menstrual function begins to be normally irregular and the epoch of its cessation—a period which women appropriately call the "dodging time"—purgatives are useful, no doubt; but we must remember that the menstrual function sometimes ceases by a gradual diminution of the quantity of the secretion and the time it occupies; sometimes by a series of irregularities in the quantity, quality, and epochs of its appearance; sometimes by a terminal flooding. Although nature occasionally chooses this last termination, we have no right to risk the possible dangers of its induction by the exhibition of purgatives which are energetic in their action. It seems to me injudicious to give purgatives just before the menstrual epoch, for they might increase the flow which nature seeks to diminish; on the contrary, it is more prudent to prescribe the frequent use of the milder opening medicines, which may diminish by degrees the plethora of the abdominal viscera.

In some women, after cessation, the stock of vital productivity is fairly exhausted, and purgatives are not absolutely required; but in most there is a superabundant nervous energy, and a superabundance of blood, for that supply which was formerly sufficient for the maintenance of both mother and offspring, can thenceforth only be expended on the woman's frame, in which the circulating system tends to assimilate to that of man.

This superabundance of blood and nervous energy may, after cessation, be frequently kept under by the frequent use of purgatives given habitually in small doses, for the intention is not to bring on a return of the menstrual discharge, but to diminish abdominal plethora, and the necessity for that plethora, seeking for a less manageable safety-valve; and as it may be some months before the constitution has settled down,

it would be advisable to consult the patient as to what medicine she has best tolerated.

With respect to the purgative to be prescribed, much depends upon the patient's constitution, for as a long-continued action will be required, it is better to make use of some mild purgative which has been found to agree with the patient.

I frequently prescribe the soap-and-aloes pill of the Edinburgh Pharmacopœia, ordering five or ten grains to be taken with the first mouthful of food at dinner. Hæmorrhoidal affections I have never seen *caused* by this frequent use of aloes, but I have seen them *relieved* by it; and as I read in Giacomini's "Treatise of Materia Medica" my experience on this point is confirmed by that of Avicenne, Stahl, Cullen, and his own, so I think there must be some exaggeration as to the extraordinary property generally ascribed to this valuable drug, which can be associated with hyoscyamus, and is thus said to be less liable to induce piles. Kemp and Hufeland recommend the following powder to be given to those who are advanced in years, and who complain of a tendency to vertigo:—Guaiacum resin, cream of tartar, of each half a drachm, to be taken at night. This, no doubt, will sometimes be found a useful laxative; so will the popular remedy called the Chelsea Pensioner, of which Dr. Paris has given the following formula in his excellent Pharmacologia:—Of guaiacum resin, one drachm; of powdered rhubarb, two drachms; of cream of tartar and of flowers of sulphur, an ounce of each; one nutmeg finely powdered, and the whole made into an electuary with one pound of clarified honey: a large spoonful to be taken at night. I generally administer the flower of sulphur alone, or else to each ounce of it I add a drachm of sesqui-carbonate or biborate of soda, and sometimes from five to ten grains of ipecacuanha powder. One to two scruples of these powders, taken at night in a little milk, is generally sufficient to act mildly on the bowels, and I consider such combinations as very valuable when a continued action is required.

I feel obliged to class sulphur amongst purgative remedies because such is its visible action, but I believe that it owes its chief value, in diseases of cessation, to another action, much more difficult to understand, and which has long rendered it so valuable both in hæmorrhoidal affections, where there is an undue activity of the intestinal capillaries, and in skin diseases marked by a morbid activity of the cutaneous capillaries. Whether sulphur cures by acting on the nerves or on the blood-vessels, or by modifying the composition of the blood itself, is difficult to tell, but it does certainly cure the diseases I have enumerated. It forms part of many popular remedies for the infirmities of old age, was recommended by Hufeland, and is lauded by Dr. Day in his work "On the Diseases of Old Age;" but its utility is not generally known in all derangements of the menstrual function, at whatever period of life they may occur, and particularly at the change of life, where, if required, its action may be continued with impunity for months and years.

LOCAL TREATMENT.

Nothing can be more erroneous than to consider a leucorrhœal discharge occurring after the cessation of menstruation as indicating a serious disorder of the womb, requiring local examination and caustic applications; for, as I have shown, inflammatory diseases of the womb generally lose their intensity and become less frequent when the generative apparatus is affected with a species of atrophy. A discharge occurring at that time is rather to be considered as a preventive of more serious disturbance. It will be remembered that I found the frequency of leucorrhœa to be as follows:—

Leucorrhœa existed in	58	per cent.
,, was augmented in	44	,,
,, was stationary in ...	8	,,
,, was diminished in ...	6	,,

The rule I adopt in such cases is not to check but to regulate this vicarious discharge by increasing the solubility of the bowels and the habitual moisture of the skin. Frequent lotions with tepid water may be recommended, but I very rarely order injections of tepid or cold water, and even when these are necessary, seldom with the addition of any astringent substance.

If, however, the discharge be very abundant, smells offensively, and has an acrid action on the skin, if it be accompanied by a great amount of lumbar and sacral pains, it is most probably secreted from an ulcerated surface of the womb, and it would be the height of absurdity not to ascertain, by a proper examination, what is the real nature of the case. If it be a cancerous affection, it is better to know the worst, but, as in the case of Frances Webb, given in a former paper, it may be only one of those inflammatory affections of the womb, which, however much they resemble cancer in some of their outward appearances, nevertheless admit of rapid and radical cure by those surgical applications which my venerable teacher, Professor Recamier, of Paris, first introduced into practice some forty years ago.

Such cases are of rare occurrence, but when they do happen they require local as well as general treatment; and if I had not already protracted this work to a greater length than I at first intended, it would be easy to prove this position by cases from my own practice.

I have passed in review the principal remedial measures by which diseases incidental to the change of life can best be cured. There are others, valuable perhaps, but which have now lost the importance attached to them when the medical mind was instinct with other theories than those now in vogue.

Thus, Gardanne, in 1816, was of opinion that "no remedies are more useful in diseases of cessation than blisters, issues, and setons." Now, I must own that on account of the subjection these remedies entail, and the real infirmities they create, I participate in the prejudice entertained against them by women, and for this very reason I should be sorry if my not adopting them should in any way diminish the good opinion others may entertain of their efficacy. What has been said in praise of alkaline preparations, of baths, of exercise, and of the advantage of a studious cultivation

of the pleasures of nature, rather than those of society, by women at the change of life, will clearly point out how the combination of all these agencies, as they are to be met with in so many agreeable watering-places, both at home and abroad, may be made serviceable for the cure and prevention of disease. For those blessed with ample fortunes, the safely getting over a critical period of life, and the remodelling of a constitution so that it may endure for many years, might be made a mere pastime if proper directions had been given by those who have written on mineral waters, respecting the nature of the springs to be recommended and the manner of taking them; but unfortunately this has not been done. The medical attendant at each medicated spring becomes imbued with so strong a feeling of idolatry for his own Egeria, that we cannot help smiling at the tales of wonder he recounts; but few of these wondrous tales relate to the utility to be derived from these mineral waters by women at the change of life; and I have even sought in vain in Mr. Edwin Lee's valuable continental medical guide, for the precise information on that matter which patients so much require. During a long residence in France, Germany, and Italy, I paid great attention to the subject; but the law of the just proportions between the component parts of a work, however small, an appreciation of which has already prevented my entering so fully as I am prepared to do into the study of pseudo-narcotism, and of other interesting phenomena of menstruation, now again forbids my writing a long chapter on mineral waters. I shall, therefore, merely enounce the following general propositions:—

1. That whatever mineral water is given, it should be in the mildest form, otherwise much mischief may be done, by causing fever to come on at night, or by inducing a state of nervous excitement.

2. That according to the different cases do patients derive most benefit from the alkaline waters, from those containing carbonic acid gas, or from the sulphureous springs, but not from the ferruginous waters.

3. That the baths should only be taken of a temperature imparting a grateful sensation, and, notwithstanding the rules of the establishment, they should not be continued for more than half an hour at a time.

4. That, generally speaking, patients will derive more benefit from bathing in sulphureous waters three or four times a week, than from taking them internally.

5. That, on the contrary, patients will in general derive more benefit from drinking those alkaline or effervescing waters, which induce a slight solubility of the bowels, than from bathing in them.

6. That, as it is often recommended to bathe in the sulphureous, while an alkaline or effervescent water is to be taken at meals or during the day, it is not without advantage to resort to those watering-places which combine a variety of springs.

8, York Street, Portman Square.

Hospital Reports.

DENBIGHSHIRE INFIRMARY.

CASES ADMITTED UNDER THE CARE OF RICHARD LLOYD WILLIAMS, M.D., F.R.C.S., CONSULTING-SURGEON TO THE DENBIGHSHIRE INFIRMARY.

Read before the Meeting of the North-Wales Branch, June 7th, 1851.

Case of Encysted Tumour of the Eyeball.

THE following is the history of the case previous to the patient coming under my notice, in the words of a highly-respectable surgeon at Machynlleth:—

"13th Sept., 1850.

"Sir,—I am desired by Miss ————, on behalf of a young woman who is anxious to be admitted to the Denbigh Infirmary, and placed under your care, to give you a short history of her case:—

"Mary Williams, aged 18, a dressmaker, has been suffering for a long period from a protrusion of the right eyeball. The disorder commenced ten years ago, and gradually increased, without much suffering, during the first six years, and then became stationary, presenting the appearance now seen. Vision has been good till the last two years, since which time it has become much impaired. The protrusion (according to her account) is at times perceptibly smaller. She has suffered much pain during the last four years, and especially during the past week, when it became excessive, shooting from the eye to the forehead and temple. Her general health has been good, and bowels regular. Catamenia appeared for the first time three weeks ago. She has been under the influence of mercury and iodine, and had a seton in the nape of the neck for six months, without any perceptible benefit. The slowness of its growth, and its arrest for so many years, combined with the good state of the patient's general health, would indicate that the affection is not of a malignant character, and that it is a favourable case for extirpation, if deemed necessary.

"I remain, Sir, yours obediently,

"HUGH LLOYD."

On the 7th of October Mary Williams was admitted as an in-patient of the Denbighshire Infirmary. The eyeball protruded extensively, and her sufferings were very great, both on the orbit as well as through the head to the occiput. Her general health was very little impaired. After giving the patient a few days to recover the effects of her journey, and administering to her some house aperient medicine, I had a consultation with my colleagues, and it was agreed that an operation should be attempted, for the relief of this formidable disease. I determined to make an incision through the upper eyelid, so as to expose the tumour, and to be guided by appearances. If I found the eyeball involved in the disease, I proposed to remove the whole mass. Chloroform was judiciously administered to the patient by my friend Mr. Turner. Upon making an incision along the whole of the eyelid covering the tumour, and making a careful examination of the parts,

I was gratified to find the eyeball totally free from disease. The tumour I found occupied the whole of the orbit, even to its very bottom. It firmly adhered to the eyeball on its lower, and to the orbit on its upper, side. My friend Mr. Chambers steadily held a tenaculum which I had passed through the tumour, and gradually drew it out, whilst I carefully dissected it from its attachments above and below. Notwithstanding the effect of chloroform, there was a good deal of writhing during this process, and the sac was ruptured, and its contents escaped. With the aid of a hook, and a pair of crooked scissors, used for the operation of squinting, I succeeded in clearing away the whole of the adhering sac from the bottom of the orbit. Although there was a good deal of hæmorrhage during the operation, it nearly ceased before I had completed it. The exterior wound was brought together by four or five sutures, and lint dipped in cold water applied. An opiate was given, but immediately rejected. The patient suffered considerable pain in the eyeball and head for eight or ten hours, when she became perfectly easy, and more free from suffering than she had been for months. The external wound healed by the first intention.

I removed the ligature at the end of four or five days, and upon gently raising the eyelid I was gratified to find the eye perfectly healthy, and the vision very slightly impaired, and it gradually recovered so as to be quite as good as that of the other eye before she left the infirmary, which she did at the end of a month from the date of her admission. The only deformity remaining at the time of her discharge was a little falling of the eyelid, produced by the extreme distension and protrusion of the eyeball previous to the operation, and which I am willing to hope time will remove. I have since heard that all deformity has disappeared, and the patient remains perfectly well.

Case of Complication of Hernia, Hydrocele, and Scirrhous Testicle.

This case is more remarkable on account of the complication of diseases existing in the same scrotum simultaneously, than from any particular feature in either.

Roger Davies, aged 70, was admitted into the Denbighshire Infirmary, on account of strangulated scrotal hernia, which was reduced by the taxis, with the aid of tobacco injections. After the reduction of the hernia the patient was perfectly free from pain, but the bulk of the scrotum remained very considerable. There was evident fluctuation, and upon introducing a trocar a large quantity of dark coloured serum was discharged. Notwithstanding the reduction of the hernia and the evacuation of the fluid from the tunica vaginalis, a hard mass still remained, which, upon examination, proved to be a scirrhous testicle. He was a fine old fellow, and upon my observing that his troubles were not at an end, and that his testicle was diseased, he said,—"Then pray take it off and make a good job of me." This was immediately done, and in the course of a few weeks the old man was rewarded for his courage and discharged quite well.

Case of Ununited Fracture of the Humerus treated by Excising the Ends of the Bones.

Cadwalader Lloyd, admitted January 20th. The history he gave was, that he had been thrown from a horse, who had kicked him severely while on the ground, some months previous to his admission. After a trial of pressure, friction of the extremities of the bones, &c., I determined upon cutting down upon the fracture, and sawing off the ends of the bones. A pretty free incision was made in the posterior portion of the arm, so as to avoid the blood-vessels and nerves which traverse the inner part of the humerus. I found the upper portion of the fracture completely embedded in, and firmly adhering to, the fibres of the triceps muscle. The spiral nerve was avoided by a spatula, held so as to keep it out of the way of injury. The inferior portion of the fractured bone, was firmly fixed in the body of the biceps muscle. It required much caution to dissect the spiculated portions of the bones from the fibres of muscles to which they firmly adhered. This, however, was accomplished, with the loss of only a few drops of blood. The extremities of the bones were sawn off and the parts brought into complete apposition. Splints were applied.

My patient was allowed to get out of bed and try the strength of the arm towards the end of April, when the bones were found perfectly and firmly united, and he was soon afterwards discharged cured. During the following summer I heard that he could use the arm with as much strength as ever he had done.

Case of Stricture, caused by External Injury, treated by Incision.

Peter Pierce, a miner, fell from the top of a shaft, straddle-legs across a beam. He was promptly attended by my talented friend Dr. Roberts, of St. Asaph, who informed me that he found the scrotum and perineum much swollen, and there was a complete retention of urine. Dr. Roberts freely scarified the parts with a scalpel, to prevent infiltration of urine into the cellular membrane. No instrument could be introduced into the bladder.

A few days after the accident I met Dr. Roberts in consultation. Failing in my attempts to introduce a catheter, we agreed to puncture the bladder through the rectum, which produced instant relief, and the canula was left in the bladder for some days, when the urine began to pass through an aperture in the perineum. As the patient was residing some distance from St. Asaph, I had him removed to the Denbighshire Infirmary. After long and persevering efforts to obtain a passage through the urethra, and failing to remove the obstruction, I determined upon making an incision in the perineum. Having introduced a staff into the urethra, and cutting down upon it, I found the membranous portion of the canal perfectly callous to the extent of half an inch. I then made an incision through the hardened parts, introduced a silver catheter into the bladder, and secured it there. It was left in the

urethra for some days and then only introduced occasionally.

The urine continued to dribble through the old aperture in the perineum for some time, but the passage was eventually restored, and he was discharged perfectly cured.

Case of Vesico-Vaginal Fistula treated by the Actual Cautery.

My friend, Mr. Chambers, has requested me to relate a case which fell uuder our joint care at the infirmary.

Ann Davies, a poor half-witted girl, was admitted December 18th, 1850. Upon examination, she was found to have a small fistulous opening between the bladder and the vagina. As far as we could collect from the poor creature, she had suffered a long and difficult labour some months previous to her admission. Soon afterwards the urine was found to dribble down her thighs.

Mr. Chambers applied the actual cautery to the aperture, and passed a catheter into the bladder, and secured it by tapes, &c. The patient was directed to lie upon her face. She was decidedly better after the first application of the cautery, and a second application succeeded in completely obliterating the fistula, and she was discharged cured.

Provincial Medical & Surgical Journal.

WEDNESDAY, OCTOBER 1, 1851.

The following notice has been handed to us by the President of the Council for insertion in the *Journal*:—

Provincial Medical and Surgical Association.

NOTICE.

The Council of the Provincial Medical and Surgical Association hereby offer a Prize of Twenty Guineas for the best *Series of Reports of Medical Cases* that may occur in any of the Provincial Hospitals, which shall be sent to the *Provincial Medical and Surgical Journal* for publication, between the First of October, 1851, and the First of October, 1852.

The Council also offer a Prize of Twenty Guineas for the best *Series of Reports of Surgical Cases* that may occur in any of the Provincial Hospitals, which shall be sent to the *Provincial Medical and Surgical Journal* for publication, between the First of October, 1851, and the First of October, 1852.

House-Surgeons and Pupils of the Provincial Hospitals to be eligible candidates for the Prizes.

In order to insure perfect fairness towards all those who may send reports, we would suggest that all candidates should, as is customary in similar competitions, send their reports with a motto or initial signature attached, accompanied by a sealed letter containing the real name and address. By these means we shall avoid all imputation of favouritism in our selection for publication. To those gentlemen who may send reports, we would also suggest the propriety of condensing them as much as possible, as we shall certainly not be able to publish those which are sent at an unnecessary length; nor should we, under the circumstances, feel justified in condensing them, or doing more than correcting any literal errors.

We beg to remind the students of the provincial hospitals, that they are included in the terms of the notice, and that it will be a considerable advantage to them, in after life, to be able to show that they have received a prize for the best series of hospital reports awarded by the Council of such a body as the Provincial Association.

It is much to be regretted that there should be any—even the slightest appearance of difference among ourselves as to the treatment of irregular practitioners, whether homœopathists, hydropathists, or mesmerists, and we think that Dr. W. Davies, whose letter we inserted in our last number, will, on reflection, consider that he has denounced the proceedings at Brighton as unnecessary, and in fact injurious to the cause they were intended to forward, without sufficient grounds. We are inclined to agree with our correspondent "F.R.C.S.," that Dr. Davies has entirely mistaken the object of the resolutions passed at the anniversary meeting. From his letter it would appear that he thinks the Association have attempted to coerce the *public* in their choice of their medical attendants, but so far from this being the case, it will be found that the whole of the resolutions are framed with a view to regulate our intercourse with one another only, and to draw the line beyond which we cannot step, where we have reason to believe we should, by so doing, afford a sanction either to fraud, ignorance, or folly.

As "F.R.C.S." has more at length shewn, this is not a question of expediency, but rather one of obligation and duty to ourselves and the public; for we believe, that in holding professional intercourse with the professor of

homœopathy, we stultify ourselves, whilst we are leading the public to conclude as they naturally do, that the regular practitioner and the homœopathist are the disciples of two parallel systems, each gaining the same goal, but by two different roads.

We would, therefore, again remind our readers that the conduct to be pursued towards irregular practitioners need not be imitated towards their dupes, who frequently are more to be pitied than despised. Let them, if they will, support this or that homœopathic hospital, whilst fashion gives it prominence: with this we have no concern, further than to lift up our voices when called upon in denouncing error when publicly promulgated. But we cannot think that we are open to the charge of persecution in purging our own body from those whom we think guilty of irregular and false practices.

The recent proceedings have already alarmed the homœopathists, as they have thought it necessary to commence an association for their protection "from the recent proceedings of some of the Scotch Universities in refusing their degrees to homœopathic students; and, if necessary, to obtain a charter to license such as are qualified." We may, however, confidently rely upon the good sense of the public in the long run; and we may rest assured that if we do not really overstep the bounds of prudence and propriety the scales will fall from the eyes now dimmed and deluded, and, as is now so often the case in really serious diseases, the regular practitioner will no longer have to complain, that in chronic complaints the advice which would be declined as disagreeable or troublesome when given by him, is eagerly followed when administered by a fashionable quack.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

JUNE 5TH, 1851.

W. PARTRIDGE, ESQ., IN THE CHAIR.

Tubercular peritonitis; displacement of the stomach; copious effusion of blood; lungs nearly free from tubercle; chief symptoms—constant severe vomiting.

By DR. RUSSELL.

MARY MASON, aged 39, married. I visited her today (May 3rd, 1851) at Mr. Welch's request. Her history was given to me very imperfectly. The following particulars I gained in great measure after the information afforded by her *post-portem*:—She had an attack of "inflammation of the bowels," towards the end of last year, by which she was confined to bed for three weeks; she had then pain in the right side of the abdomen. She appeared to recover entirely. About Christmas she had an attack of bilious vomiting, generally coming on about evening. Her present illness is of four week's duration; she has kept her bed a fortnight, having suffered severely from sickness a fortnight previously.

I found her greatly emaciated and evidently sinking rapidly from advanced disease. She had constant vomiting, which was in some measure checked by opium, though very imperfectly. The rejected matter was described by Mr. Welch and by her attendants as being exceedingly offensive, so much so that they could not preserve specimens for examination; some that I saw in later visits, was of a bilious colour, thick, and had a most unpleasant smell, partly fœcal, partly bilious; this was the case with every specimen examined. Her bowels were open regularly. There was some fulness of the bowels generally, but nothing evidently abnormal, except that in the left lumbar region of the abdomen my attention was attracted by a peculiar and decided though somewhat obscure fluctuation, diffused over that region, but not felt in any other part; that region of the abdomen was decidedly duller than the right side, though still partially resonant; and there was no local distension, nor could I trace the outline of any cyst. This symptom continued to present itself at several subsequent visits; the explanation of it I was disposed to assign, was displacement of the stomach, but I was at a loss to explain such displacement, the few particulars afforded me of her history, not throwing sufficient light upon her disease. She lived till May 25th without presenting any fresh symptom. The vomiting was somewhat relieved by opiate suppositories, (she could not retain medicine) but still continued very troublesome. She had a tendency to diarrhœa towards the last.

Sectio-cadaveris thirty-six hours after death.—Great emaciation; slight rigor. *Thorax:* Some fluid in the left pleura; adhesions general of the right lung and at posterior part of the left; *right* lung *healthy and free from tubercle;* in the *left*, scattered through its tissue, were several firm nodules of minute grey granulations, in some few were what appeared to be miliary tubercles, in very small number, and in two or three cretaceous deposit, in a state like mortar. *Heart* healthy. *Abdomen:* On opening the front of the abdomen an extended layer of coagulum appeared, entirely concealing the contents of the cavity lying over the front of the liver, and on the intestines, and dipping down into the pelvis; the coagulum, when removed, proved of considerable thickness; the true pelvis contained a very large quantity of coagulum and bloody serum, by which indeed it was almost filled; there was some bloody serum in the abdominal cavity besides. All the intestines were closely united to one another by cellular adhesions, plentifully filled with tubercular matter; they were entirely separated from the abdominal wall by the coagulum, but from the resistance offered to the removal of the walls of the abdomen it seemed probable that there were adhesions also between it and the intestines. The *liver* adhered closely to the diaphragm

throughout its convex surface; it was much flattened, its tissue very confused, soft, friable, in many parts nearly pulpy, and was throughout of an ochre colour. The *gall-bladder* healthy, its interior studded with tubercles; it was empty, but coated within with gamboge-coloured tenacious liquid. The *stomach* was quite displaced, it was tilted down into the left side of the abdomen, so as to be entirely on the left side of the middle line, and to occupy the left hydochondrium, and upper part of the left lumbar region of the abdomen; it was nearly empty. The transverse colon adhered so closely to the pylorus, that for some time it was believed to be a greatly distended duodenum. The small intestines presented their natural calibre; their folds admitted of being separated. The ascending, and particularly the transverse colon, were much distended with flatus; the descending colon very much contracted and contorted by the adhesions; sigmoid flexure of the upper part of the rectum was greatly contorted by the adhesions; it was contracted also in its calibre. The cœcum contained a little stiff fæces. The stomach was healthy internally; the mucous membrane throughout the intestinal canal, was healthy, except that it was very pale; the walls of the stomach and intestines attenuated; omentum much thickened and contained tubercular matter; kidneys, pancreas, and spleen healthy; one ovary was converted into a small cyst, with thick dense walls.

With reference to the hæmorrhage I should add, that the last four or five days I had remarked great pallor, but did not attach any importance to it, from her dying condition.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

Among the recent communications to the Academie de Médecine, is one of great interest by M. Orfila, "On *Poisoning by Nicotine.*" This distinguished chemist states that nicotine may be recognized as readily as any of the mineral poisons, and that the detection is possible even when it exists in the stomach or intestines in the minute quantity of a few drops. It may also be discovered in the liver and other organs after it has been absorbed. Nicotine presents itself as a colourless oleaginous liquid of the specific gravity 1.048, the taste is very acid, its smell that of tobacco. Volatilized at 250°. It burns with a white sooty flame. It is strongly *alkaline* to litmus, and is soluble in water, oil, and in ether. This great solubility both in water and ether, is stated to be very characteristic of nicotine, and does not occur in the case of other alkaloids. Given in the dose of a few drops to a dog, it produced vertigo, followed by convulsions and coma, without vomiting or purging. Death occurs in a few minutes.

M. Orfila gives two processes for the detection of nicotine, the first of which we here record:—The contents of the stomach and bowels are to be mixed with and macerated in ether for twelve hours. At the end of this time the nicotine will be dissolved by the ether, with or without fatty matters, as the case may be. This ethereal compound is next evaporated to dryness, and mixed with a solution of caustic soda, which separates the fatty matters, and it is then distilled. The nicotine will now be found in the receiver.

The second process produces a sulphate of nicotine, which is decomposed by potash, and distilled as before.

Another fact established by M. Orfila, of great importance, in a medico-legal point of view, is, that nicotine is not destroyed by putrefaction, but may be detected after the body has been dead two months.

A paper was also presented by M. Desgranges, "On the *Treatment of Prolapsus Uteri, by pinching up* (pincement) *portions of the Vagina.*" This is accomplished by means of small instruments, which enclose folds of the vaginal mucous membrane, and are allowed to remain until ulceration occurs. The subsequent cicatrization so contracts the calibre of the canal, as to prevent the falling of the womb. The number of instruments used varies from three or four to nine, and the treatment extends through three or four months.

[This is a modification of the operation proposed by Dupuytren and Marshall Hall, but is more tedious.]

Among the memoirs of less interest may be mentioned the following:—"*Researches on the Alkalinity of the Blood*, by M. Le Canu; "*Report on Vaccination*," by M. Bousquet; "*On the Employment of Strychnine in General Paralysis of the Insane*, by M. Girard; and "On two new Alkaloid Salts—the *Tannate of Quinine, and Cinchonine*, by M. Barreswill.

ACADEMIE DES SCIENCES.

Persistence of Vital Properties in Muscles during Cadaveric Rigidity.—M. Brown-Seguard has announced the remarkable fact that limbs which have become rigid after death, may be made to exhibit muscular irritability and sensibility. This he proved by injecting blood into the vessels of the stiffened limb. The following are the author's conclusions:—1. That muscles are not necessarily dead because they exhibit cadaveric rigidity—that, if they are not actually alive, they have the faculty of living. 2. That want of circulation of the blood deprives the muscles and nerves of their functions: the restoration of the circulation restores these. 3. That notwithstanding the duration of rigidity shall have been as long as twenty minutes, sensibility and voluntary movements may be restored.

[These researches were made on living animals by means of disgusting cruelty, such as only a French physiologist could perpetrate.]

On the Importance of Bile in Digestion.—M. Blondlot has ascertained that, contrary to general belief, the bile has no office of importance, but is purely excrementitious, and that, by consequence, it might cease to flow into the intestinal canal without interruption of the process of digestion for all purposes of the maintenance of life. M. Blondlot called the attention of physiologists to the chief fact of his essay, which was the establishment in living animals of fistulous

openings carrying off the entire quantity of bile, the normal duct being obliterated. In the animals thus experimented upon digestion took place perfectly, as in other animals. In one animal the bile had been thus carried off externally during a period of five years; at the end of which time, the animal having died, its body was carefully examined, and no trace of communication with the intestine existed. The uses of the bile in the alimentary canal are secondary: it contributes with other fluids to form emulsion with fatty matters, and it assists to neutralize acids; its primary office is the elimination of detritus.

Treatment of Tetanus by Chloroform Frictions.

In the *Union Médicale* the following case is recorded by M. Morrisseau. The patient was about forty years old, a man of good constitution. Eight days before admission he had slightly wounded himself on the front of his leg, while at work, with his pick-axe. The trifling wound had healed by the fifth day. On the sixth day tetanic symptoms manifested themselves.

The patient was at first treated at home, but the disease advancing he was removed to the hospital. When first seen by Dr. Morisseau, the tetanus was fully developed; there was persistent contraction of the muscles of the jaw, of the chest, abdomen, and back; the body was bent double every hour; deglutition impossible; the pulse small and slow; nothing particular was observable of other functions.

Friction was performed with four grammes (one drachm) of chloroform. This quantity was repeated three times during the day. The patient was placed in an acidulated vapour bath. On the following day a considerable improvement had taken place. The patient had perspired freely; he had slept well, which he had not done before since the commencement of the attack; he had swallowed a few spoonfuls of liquid; the muscles were less rigid; convulsions shorter, and less frequent.

The dose of chloroform was increased to twenty grammes, three times a day. This treatment was continued for five days with the best results. All the symptoms had disappeared on the sixth day. A sense of lassitude and debility alone remained, and these soon disappeared under suitable diet.

Treatment of Scarlatina by Inunction.

This method of treating scarlatina, first introduced by Schneeman, has been alluded to in a former number of this journal: but as it is of importance to know how far the experience of others has sanctioned the practice, we here give an account by Dr. Ebert, *(Revue Medico-Chirurgicale)* who has adopted it in an epidemic which has lately appeared in Berlin, and, as he informs us, with great success. The author has had twenty-two cases, eleven of which offered serious complications; the deaths amounted to six. Of these twenty-two, thirteen were treated by frictions with lard, nine by other measures. Of the latter, five died; on the contrary, of the former, twelve got well, and one only died, but in this case death took place almost immediately after the first friction. The general remarks of Dr. Ebert are to the following effect:—

1. Frictions with lard do not induce any injurious consequences, or in any way interfere with the development of the exanthem, as might, *a priori*, have been expected.

2. The complications of scarlatina do not contraindicate the frictions; on the contrary, under their influence, the complications occur less frequently and disappear more rapidly.

3. The effect of the treatment is distinguished by the absence of desquamation in all cases in which it has been scrupulously carried out. The exceptions to this are very rare.

4. In no case thus treated was anasarca known to supervene.

5. Another apparent effect of this treatment is to destroy the contagious principle.

General Retrospect.

PRACTICAL MEDICINE AND PATHOLOGY.

Communicability of "Grease" to Man.

A case is reported from Guy's Hospital which seems to prove that the disease in the heel to which horses are subject, and called "grease," is communicable to the human subject, and produces symptoms analogous to glanders, but of much less fatal character. A case, illustrating this fact, came under the care of Mr. Cock.

The patient was an ostler, in excellent health, till he accidentally touched his nose with the matter whilst dressing a *greasy* heel. In the evening he experienced some heat of the part, which he attributed to catarrh, but next morning the cheek and nose were observed to be considerably swollen, and a thick discharge flowed from the nostrils.

On admission the nose was swollen, of a dusky red; cheeks tumid, and blotched, and on each side was a hard painful swelling, like a periosteal node. He was ordered quinine, nitrate of silver lotion (dr. ss. to oz. j.) applied to the mucous membrane, full diet, ten ounces of port, and two pints of porter daily. Next day the cervical glands were enlarged; the nose was freely punctured, with great relief. Ten grains of Dover's powder at night.

On the third day the patient had passed another restless night; he complained of dizziness and pain in the head; the nose and face were intensely painful, and the tumefaction so much extended and increased, that the eyelids were now completely closed. Two hard lumps of pus came away from the nostrils. Mr. Cock again punctured the nose, and ordered a bread-and-water poultice to be applied to it. The bowels have been well relieved. The quinine was continued, but the powder omitted.

On the fourth day a great change for the better had taken place; the patient passed a good night, slept well, and was comparatively free from pain; the tumefaction about the nose, face, and eyelids is much reduced in size, and the pain much less severe. The discharge continues from the nostrils.

From this time the man continued to improve, and seven days after admission the nose had regained its

natural size; the discharge was much reduced in quantity and consistence, and on the 26th of April he was presented for dismissal cured, having been in the hospital only ten days.

Mr. Cock remarked that this was the third case he could call to mind where the evidences of poisonous inoculation were clearly traced to contact with the greasy heel of a horse. In both the other cases the poison appeared to have been imbibed from wounds or cracks on the men's fingers, and the most severe absorbent inflammation was produced, accompanied by intensely acute constitutional disturbance.

In the one instance the patient recovered after much suffering and tedious illness; in the other he died at the end of several weeks, worn out by successive abscesses, which formed in different parts of his body. There seemed, therefore, no doubt that the greasy heel of the horse was capable of grafting a specific poison upon the human subject.

As in this case the fact of poison seemed to be clearly indicated and proved, and as the inoculation had been recent, Mr. Cock considered it expedient to endeavour to destroy the contaminated surface as speedily as possible, and to excite a healthy suppurative action on the mucous membrane of the nostrils.

The caustic solution was severely and unsparingly applied, and certainly seemed to have the decided effect of "killing the local disease." The aggravation of inflammation and tumefaction which followed the use of the escharotic, and which extended over the nose, cheeks, and eyelids, was doubtless rather to be attributed to the severity of the remedy than to the extension of the original disease. The same local effects have not unfrequently been produced where a strong solution of nitrate of silver has been injected into the urethra for the purpose of cutting short a gonorrhœal discharge.

Mr. Cock made the punctures in this case with a broad-shouldered lancet, and carried them to a considerable depth. The blood flowed from the wounds in streams and jets, showing the congested and distended state of the vessels. The relief was most speedy and effectual.

On the Use of the Neutral Sulphites in Diseases of the Stomach connected with the production of Sarcina Ventriculi.—By Dr. Jenner.

A very remarkable case is made the subject of a clinical lecture by Dr. Jenner. The main symptoms were daily copious vomiting, flatulence, distension, and the train of symptoms usually referred to cancerous degeneration of the coats of the stomach. The yeasty appearance of the ejecta induced Dr. Jenner to examine microscopically, and he found immense quantities of *sarcinæ*, with *torulæ*. The man had been treated with bismuth, nitrate of silver, and hydrocyanic acid, without any relief, when Dr. Jenner determined to give the sulphite of soda, being led to this by the known effects of sulphurous acid upon parasitic vegetable growths. The effects were gratifying, as far as regards relief, but the more ultimate effects are not ascertained. As a proof of this we give Dr. Jenner's account.

Before taking it, he was vomiting daily from 40 to 100 ounces of the fluid, loaded with sarcinæ and torulæ; thus, on the 1st of April he vomited 100 ounces; on the evening of the 2nd, between 70 and 80 ounces, although he had the same morning, from the action of sulphate of zinc, vomited 50 ounces. No vomiting on the 3rd. On the 4th, in consequence of the extreme pain and sense of distension, sulphate of zinc was again administered.

On the 5th he took half a drachm of the sulphite of potash early in the morning; in the evening he vomited. On the 6th the dose was increased to one drachm. On the 7th he vomited 12 ounces only of acid fluid, on the surface of which there was but a small amount of scum; it contained perfect sarcinæ, but no torulæ.

From the 8th he took three drachms of the sulphite daily, each dose being given in a drachm and a half of water. At six A.M. on the 9th he ejected from the stomach four ounces; the sarcinæ were now decidedly less numerous, and there were no torulæ. In the evening of the 6th he again vomited, but the vomited matters were now free from sarcinæ and torulæ, and there was no appearance of fermentation. Between the 9th and the 18th he vomited three times, but on neither occasion did the vomited matter contain sarcinæ or torulæ.

On the evening of the 18th the sulphite of potash was omitted; and on the 19th he vomited a fluid in a state of fermentation, containing torulæ, but no sarcinæ. On the 20th he vomited 9 ounces of a similar fluid; these specimens were examined by a most trustworthy observer, Mr. Morris, the physician's assistant. On the 21st there was a thick scum on the surface of the vomited matters, which contained sarcinæ and torulæ in abundance.

The sulphite of potash, in drachm doses, was again administered; no further vomiting occurred till the 27th, when, without any apparent cause, it recommenced; the vomited matters had their old yeast-like odour and appearance, and were loaded with sarcinæ and torulæ. Dr. Jenner now began to suspect that the man could not be taking his medicine regularly; but on inquiry no omission could be discovered. The medicine itself was then tested, and it was found that it gave off no odour of sulphurous acid, on the addition of a stronger acid. At the dispensary we learned that a fresh stock of the drug had come in on the 20th. On submitting a specimen to Mr. Graham, he found that it contained no trace of sulphurous acid. At his suggestion, Dr. Jenner prescribed from this time the sulphite of soda, a more stable salt, and one less liable to be decomposed either in the preparation or by keeping.

On the 29th of April half a drachm of it was given at bed-time, and on the 31st, half a drachm three times a day. On the 1st of May our patient vomited 40 ounces of a fluid covered with a thick scum; the vomited matters were not examined microscopically.

On the 2nd the dose was increased to a drachm. There was no vomiting till the 5th; the vomited matters were in quantity about 50 ounces, had no scum floating on their surface, and were entirely free from sarcinæ and torulæ.

On account of the burning pain which he occasionally complained of, he was now ordered a mixture containing sodæ carb., two scruples in each dose. On the 13th, 15th, and 16th, he again vomited sarcinæ in

quantity, and as it was suspected that the soda prevented the evolution of sulphurous acid, the carbonate was omitted. From the 16th of May to the 19th of June, the vomited matter contained no trace of sarcinæ or torulæ, and had lost its yeasty odour and appearance. *During these thirty-three days he ejected about* 230 *ounces of acid fluid; during the first eight days of his residence here he ejected* 380 *ounces.—Medical Times*, Aug. 23.

On the Prophylactic Value of Belladonna in Scarlatina.
By Benjamin Bell, Esq., F.R.C.S.

The author, in the course of a narrative of an epidemic of scarlatina, which appeared in Edinburgh in 1831, mentions the internal use of belladonna. He says that, "conceiving that no means for arresting the disease should be omitted, and that a favourable opportunity offered for testing the alleged prophylactic virtues of belladonna, he determined to give it a fair trial; accordingly, after the occurrence of the second case in the hospital to which he is attached, in which a number of boys are educated, he gave to each the fifth of a grain night and morning. This caused dilated pupil, and the dose was, therefore, diminished, and given uninterruptedly for a month, during which time no case had occurred. There was, therefore, a sufficient time for it to manifest its prophylactic power, if any were possessed, but the subsequent occurrence of several cases served to render this property doubtful.—*Edinburgh Monthly Journal*, August.

SURGERY.

Popliteal Aneurism cured by Compression over the Tumour.—By H. Bennett, M.D., (U.S.)

The peculiarity of this case consists in the fact, that the compression was made directly over the sac, instead of in the line of artery above it.

Thomas Elwell, aged 30, subject of popliteal aneurism, for which ligature of the femoral was advised. Hearing of the benefit of compression, he determined to try it, and commenced the treatment himself by bandaging the limb from the toes to the knee, and placing a compress of folded cloth directly upon the pulsating tumour. He persisted in this course for two or three months without the least benefit, when he determined to substitute a firmer compress. Instead of folds of cloth, folds of *sheet-lead* formed the nucleus of his compress, which was applied in the same manner as before. The reporter called upon him occasionally to watch the progress of his treatment, and after the end of ten days after the application of the lead compress, found him suffering much pain in the knee-joint, from the severe pressure which he had made, but no diminution in the size of the tumour, or the force of the pulsations, the latter being readily felt through the compresses when applied with all the force which he could endure. He was advised to discontinue what was considered a hazardous proceeding, and to abbreviate his sufferings by submitting to the usual operation. Notwithstanding, being a man of very strong resolution, he determined to pursue this course still longer, and abide the issue. At this time, however, he threw aside the lead compress, and filled its place with *a ball of caoutchouc*, which he bound upon the tumour with all the force he could endure. Not long after, perhaps two or three weeks, the author called again to see him, and was much surprised upon examining the limb, (which he exhibited with no little triumph,) to find the tumour much diminished in size, and the *pulsation gone.* From this time the tumour in the popliteal space was gradually absorbed, and at the end of a few months had entirely disappeared.—*New York Journal of Medicine*, July, 1851.

Results of Wounds of Articular Cartilages.

Mr. Redfern adopts the following as a summary of his observations on wounds of articular cartilages:—

1. Wounds in articular cartilages heal perfectly by the formation of a fibrous tissue out of the cut surfaces.

2. The fibrous cicatrix consists of white and yellow fibres, formed out of the intercellular substance of the cartilages, and of the nuclei of its cells.

3. Articular cartilages disappear after amputation at the joints, either by transformation into fibrous tissue or by slow ejection of their particles into a newly completed synovial sac.

4. Ulceration in articular cartilages differs from that in other tissues in neither being accompanied by exudation or attended with pain [?]—differences which depend on absence of vessels and nerves.

5. Ulcers of cartilage heal by transformation of the surrounding cartilage into fibrous tissue.

6. Inflammation, regarded as a process of abnormal nutrition with changes in blood and blood-vessels, does not occur in the cartilages of man.

7. All diseased states of cartilage are referable to abnormal nutrition of this texture, and have much less surgical importance than has been attributed to them. —*Edinburgh Monthly Journal*, September, 1851.

TOXICOLOGY.

On Poisoning with Sulphuric Acid.
By Dr. Geoghegan.

The following inferences are deduced from a paper on this subject:—

1. That in poisoning by sulphuric acid the poison may reach the interior of the larynx and bronchial tubes during life, and may thus produce a bronchitis of sufficient intensity to prove fatal, either *per se*, or aided by mischief elsewhere.

2. That the blackening of the stomach in poisoning by sulphuric acid does not necessarily involve the carbonization of the tissue, but may consist in the interstitial deposit of blood effused under the corrosive and irritant action of the poison, and chemically altered by the latter.

3. That oil of vitriol does not *carbonize* the dead stomach, but dissolves its coats.

4. That in cases of poisoning the acid may be detected in the blood and parenchymatous viscera; its quantity relatively to the weight of structure operated on, being greatest in the *liver;* and, in proportion to that of the normal sulphates, in the *blood.*

5. That in the blood and parenchymatous organs, the acid is to be discovered (and probably exists during life) solely in combination with the colouring matter and tissue respectively.

3. That the poison, when absorbed, decomposes the alkaline phosphate of the blood, and that the resulting sulphates are rapidly evolved.

7. That the above indicated method of comparative examination of equal weights, when carefully employed, appears suited to the exigencies of medico-legal practice, and is not open to any practical objection which cannot be obviated, either directly or by collateral proof.

8. That researches relative to the distribution and state of combination of substances absorbed by the blood, afford a rational prospect of improvement in our knowledge of the action of therapeutic agents.—*Medical Gazette*, August 22.

Correspondence.

HOMŒOPATHY.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—Your last number contains two important documents upon the subject of Homœopathy, which demand the attention of every member of the Association; and, as the autumn quarterly meetings of the branches are about to take place, I trust they will receive that consideration which their great importance deserves.

I allude to the memorial of the Manchester Medico-Ethical Association to the Royal College of Surgeons, and the address from the Medical Practitioners of Guernsey to the Committee of the Association, on Irregular Practice.

With regard to the first of these, I hope the Central Council of the Association will speedily bring it under the notice of the branches, in order that corresponding memorials may be presented by every section of the Association; and where branches do not exist, by the members of the profession resident in various localities. By this means the great object sought by the meeting at Brighton, will be brought prominently under the notice of the governing bodies of the profession, and convince them that the only object of the Association in this movement is the purity of our Colleges, the respectability of our profession, and the furtherance of the honourable practice of the science of medicine.

The address from Guernsey is, I would humbly opine, a cogent and forcible reply to your correspondent Dr. W. Davies, and those who think with him that our duty as members of the Provincial Association is to leave the matter entirely to the governing bodies; we are, says he, "a body of men banded together for the advancement of medical science, for the promotion of just and honourable dealings in our intercourse with one another, and for the interchange of the courtesies and ameneties of life," and nothing more. Why, Sir, homœopathy comes before us with all the authority of a system of medicine; Hahnemann himself was regularly educated; his followers have all been educated in, and taking degrees and licenses from the recognized bodies, and it differs from all other systems of empiricism in this one feature,—that its practice is solely confined to a *section* of our own profession. Surely, Sir, it is the bounden duty of "*a body of men banded together for the advancement of professional science*, to repudiate homœopathy as is forcibly done in the first resolution passed at Brighton, as "*so utterly opposed to science and common sense, and so completely at variance with the experience of the medical profession, that it ought in no way or degree to be practised or countenanced by any regularly educated medical practitioner.*"

Surely we can take no other or better mode of "*promoting just and honourable dealings in our intercourse with one another*" than by declaring in the words of the third resolution "*that it is derogatory to our honour to hold any kind of professional intercourse with homœopathic practitioners.*" Surely Dr. Davies would not have us "*interchange the courtesies and amenities of life*" with men who, although they may be members not only of our Royal Colleges, but of our own body, have poured ridicule upon an honourable profession, and who seek to thrive by trickery, empiricism, and fraud. This, Sir, is not our duty; our course plainly is to endeavour to purify our own ranks by emphatically declaring that these men and their *compeers*, the hydropathists and mesmerists, ought not to be members of our Association, or retain diplomas conferred by bodies whose principles they repudiate.

We have nothing to do with the public in this matter: we do not, as Dr. Davies seems to suggest, apply "hard names" to them. In accusing the Brighton speakers of this (by implication) he appears to wander about for reasons why he should desert a cause of which he may be said to be the leader, he having been the first in the Association to draw attention to the subject as far as it related to the Scotch Colleges. In your number for for July 23rd, I find that Dr. Wm. Davies, at the annual meeting of the Bath and Bristol Branch, "in a few terse but appropriate remarks" proposed a resolution thanking the Royal Colleges of Edinburgh for their "expressed determination to uphold the science of medicine by severing from their body those who act in a manner unbecoming the character of a physician or surgeon." Why, Sir, if Dr. Davies was justified in proposing such a resolution at a branch meeeting, he had no excuse for declining to serve on a committee appointed by the Association at their collective anniversary to report upon irregular practice, an honour which he declined, for reasons which he says will be obvious from his letter, but which I cannot see.

I envy the men who could, in so short a time, amidst the excitements of the annual meeting, sit down and frame the resolutions which were so triumphantly adopted, and to which, as yet, there has been no cavil, either in or out of the profession; and after a careful perusal of the resolutions adopted and speeches delivered, I see no allusion to the public whatever, except as dupes—none of that martyrizing process so feelingly deplored by Dr. Davies, and which he gives as his reasons for not serving upon the Committee.

Qui vult decipi decipiatur applies in this case, as in all others. I have been many years in extensive practice, and I know that my experience will be fully borne out by my fellows when I say that though the *Malade Imaginaire* may wander about from one system of quackery to another, should any dangerous malady attack him he returns to the legitimate practitioner, and ceases to "try" any more experiments or nostrums.

Sometimes, indeed, as Dr. Williams feelingly observed in his speech, our attentions are too late; but even when they are so, the victim of empiricism, by his death, advances the esteem in which legitimate medicine is held by the public.

And now permit me to draw an analogy between Medicine and the Church. Trinitarianism and Arianism are both systems of religion; medicine and surgery, as taught in our schools, and homœopathy, as taught by Hahnemann and his followers, are, for our present purpose, both systems of physic. Surely, Sir, if the Arian divine were, even by the profession of Trinitarianism, to obtain orders, he would be expelled the Church as soon as his peculiar doctrines were avowed. This has been the custom in all ages, and with all sects. Why should not medicine be guided by similar rules, and every professor of heretical doctrines be compelled to resign his diploma as soon as he no longer holds the principles and practice of his College? "He that is not with us is against us." I cannot call a man a "martyr," nor am I an "enchainer of the human mind," when I call upon our Association to pursue its good work of freeing the profession of a body of men who proclaim their heresies under the sanction of its degrees and diplomas; who, not content with the practice of empiricism as an unrecognised quackery, dignify it by the name of a system, and parade their professional titles (nay, as in many recent instances, seek them) to add a lustre to practices which every honourable man in the profession repudiates with scorn.

Our work is but half done if we do not, by every means in our power, urge upon licensing bodies peremptorily to expel from their ranks all who practise homœopathy and its cognate branches of quackery. Many profess to do so conscientiously; but surely their conscientiousness is easily stifled when, notwithstanding their entire renunciation of the doctrines taught in the schools from which they have obtained their diplomas, they still pertinaciously continue to call themselves Fellows and Members of Colleges which their practice tends so much to degrade and insult.

Without these titles homœopathy in this kingdom would sink into oblivion. No ship fears the approach of the pirate who sails under the flag of a protecting power. Do not the patients of these men tell you that Dr. Globule is a Fellow of your own College? Do they not refer you to the prizes he obtained as a pupil; and tell you that you only differ in your "*systems*;" that he has been convinced of the "*errors*" which you, in your blindness, pursue without reflection? In their eyes you are both equally qualified to treat disease. For this state of things there is but one remedy, namely,—expulsion from the ranks of medicine; and until this is effected the Association should persevere in its present movement.

I am, Sir, your obedient servant,

F.R.C.S.

To the Editors of the Provincial Medical and Surgical Journal.

Dear Sirs,—A letter in our last *Journal* from Dr. Davies, wherein he somewhat condemns, as regards homœopathy, the proceedings of the Annual Meeting at Brighton, I cannot allow to pass unnoticed.

I regret extremely that I was wholly unable to attend that interesting meeting, the more so as I feel as strongly as any member present, on the heresy which has crept into our professional ranks, and, in my humble opinion, the remarks made by the several speakers on this subject were most judicious.

I do not for one moment complain of the amount of public support homœopathy has received, were it far more extensive than it is; but let us enter our solemn protest against having anything to do with what will, some day or another, prove to be one of the greatest humbugs ever palmed upon man. Let us never meet the professors of this system in consultation, either directly or indirectly; let our Colleges be purged of them; let them have colleges of their own; and, were it not that I consider I should be encouraging error, I would most gladly assist them in this effort, feeling convinced that the sooner the system is allowed to stand on its own basis, the sooner will a discerning British public detect its hollowness, as well as its dangerous tendency.

Believe me, dear Sirs,

Yours faithfully,

JAMES HEYGATE, M.D., F.R.S.

Derby, Sept. 18, 1851.

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—I begin this letter with two questions:—Is there such a disease as insanity? Should not an Act be passed declaring there is no such disease; and that confinement, or restriction of liberty, under the presumption of mental aberration, is violating the rights of the subject?

Under the present management and laws for regulating private establishments, such would be the more sensible plan. The proprietors of private establishments are at the perfect mercy of the Commissioners; their visits are inquisitorial, their court a star chamber, and the Act gives no appeal. Their report has to be returned to their office in London, and also to the Sessions' Clerk. No matter what it may contain;—no matter that it may be merely the impression of the mind of *the then visitors*;—no matter if contradictory to a former report;—no reason assigned, go it must, and cannot be altered, nor, as far as I can yet judge, are any explanations which may be offered, attended to.

I have said the visits of the Commissioners are inquisitorial; as such they may come at any hour they please; and I have known them, coming at an early hour, find much fault because the house was not in perfect order, totally unmindful of the morning work in a house where there are dirty patients, and even excepting that, of the regular process of cleaning absolutely necessary, from the palace down to the cottage. How would they like their own domicile to be so early visited, and its state of cleanliness minutely reported!!

Again. Whatever length of time the visitors may stay, they cannot make themselves acquainted with the

habitudes of the patients. If the Act be intended to be of service, which I much doubt, each Commissioner should remain three days at board and maintenance, and perhaps sleep in the same room with a patient, whom he might think unjustly restrained; he would, probably, then get some insight as to the proper modes of conducting and managing difficult cases.

At present it is perfectly impossible for any Commissioners' opinion to be of any value. He presumes to himself he knows how to treat an insane patient. He knows nothing, and can know nothing, without opportunities for such knowledge being afforded him, and yet what observations are made, what peremptory commands placed in the "Visitors Book," totally incompatible with the patients' state. For instance, at the last visit of the Commissioners to a small, well-regulated establishment, solely for females, two perforated chairs were ordered to be broken up, although it was explained that the patient, for whose use they had been principally procured, would never perform the necessary natural functions, unless placed in one of them, but would take every opportunity of dirtying herself, or the ladies' room. In my own establishment I have a patient who *requests* the waistcoat may be placed upon him at night. He feels his irritation constantly preventing sleep; but one Commissioner thinks some other means might be adopted, but refrains from stating what those means might be. I wish the Commissioner would pass one night in the room, and then he might more accurately determine his opinion. An attendant sleeps in the same room, and it would weary out the lives of two, unless this mode of obtaining calmness was resorted to. I hesitate not to say that theoretical ideas as to the mode of conducting the comforts or returning health of an insane patient, are as nothing compared to the results of practical experience. The law as it at present stands is a one-sided and unjust law, but a very valuable one to those who have an interest in its continuance; and fault can be easily found by those who seek for it. I speak not particularly, but generally; and if the general body of proprietors of private asylums are satisfied, my remarks, of course, are useless, but they may be one day surprised at their exceeding supineness. There is much property vested in these private asylums; but that, of course, is as nothing compared with the results of their curative influence, or of their power, when cure is hopeless, of affording means of management so as to promote a comfortable existence; and this is beneficial to both parties. Is there a director or attendant who would not rather obtain for his patient and himself rest and quietness than constant wearying watch, both by day and by night; and surely we all know such a result is best obtained by kindness and firmness. As far as my experience, of a tolerably long standing, justifies the observation, an attendant will always incline to the former; and what Commissioner will name, from his own observations, one director who is not much more satisfied with the regularity and pleasant feeling of his or her establishment, than with constraint, seclusion, or immethodical treatment.

Again. I presume to observe that the law establishing the Commissioners of Lunacy, is neither useful, nor can be useful; it often promotes strife,—it often engenders bitter feelings. It seems to me, from all I have endeavoured to obtain information, to endeavour to find fault, and to accept it readily. I am sorry to say it affords a means of publishing individual cases of diseases which ought, for many reasons, to be kept silent.

Power is inherently pleasant in the mind of man. Power will also give a supposition of excellence; also an emulation of being more wise than those preceding

"Semel insanivimus omnes."

Yours obediently,

E. B.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—I have this day read a paper calling itself "The Alleged Lunatics Friend Society." A more impertinent paper calling itself a "report" I never read; but when I see one name attached I less wonder at its wild enthusiasm and want of common sense. Some three or four cases are searched up and protruded with much flourish of trumpets, in which there may or may not have been mal-practices, for the evidence is doubtful; and the illegality is, not obeying to the letter the law propounded in the Lunatic Act—an Act yet difficult in comprehension, and, in regard to certificates from parties residing in the country, impossible to be immediately obeyed. This the Commissioners themselves acknowledge, and are patient in allowing such inaccuracies to be set right. But this searching report can find nothing to detail but what has been before the public and already adjudicated. Irregularities have been proved as to orders, certificates, entrances—irregularities of books, but the characters of the proprietors have remained unimpeached; and although all laws must be obeyed, yet what are informalities compared to the due regard to the health, convenience, and comfort of the patient? The report of the "alleged" may be formed to subserve some purpose; but I think this age, though Quixotic enough, will not establish windmills to fight with. To believe the report would be to believe that no advance has been made in the history and treatment of insanity, but that we have rather deteriorated, and have returned to that state of barbarism when whips and chains were common modes of treatment;—when that treatment was directed not so much by cruelty as by thorough ignorance of the forms and nature of the disease, and by direct belief that a case for insanity was hopeless, and that nothing remained but to reduce violence or obstinacy into obedience, as Dr. Busby, of celebrated Orbilian memory, well knew how.

I affirm that the good character of private asylums is generally acknowledged; that the medical and moral treatment is conducted upon principles based upon the welfare and comfort of the patient—witness the now many cures—and that the petition of this "alleged society" results from mistaken enthusiasm—from generalizing upon imperfect information, and from that pernicious maxim, "exuno disce omnes."

Yours obediently,

E. B.

THE FINANCIAL STATEMENT OF THE ASSOCIATION.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—The treasurer of the Association at the meeting of the Council, held at Brighton, read a supplemental balance sheet, or liability-sheet, in addition to the account of the finances published in the last number of your Journal.

I understood that such supplemental document would be published, as well as the balance sheet. As a member of the Council, and one of the auditors of the Association's accounts for the year ending August 1, 1850, I beg through your columns, to intimate my wish and hope that such supplemental document may be laid before the members in your columns.

I am, Gentlemen,
Your obedient Servant,
SAMUEL CROMPTON.

Manchester, Sept, 10, 1851.

[We understand from the Treasurer that he simply stated that, in addition to the balance in the cash account, there was upwards of £1000 due for subscriptions; and that there was also a stock on hand of "Transactions" and Journals of small value. The liabilities of the Association at the end of July, amounted to about £120.—ED. P. J.]

DR. MAYNE'S EXPOSITORY LEXICON.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I sincerely hope the profession generally will respond to Dr. Mayne's request, and subscribe to his Expository Lexicon. Lest any one may be inclined to withhold their name from a reluctance to support a work about to appear in parts, I hope my testimony in Dr. Mayne's behalf will induce them to reconsider their decision, and at once come forward and give the Doctor a helping hand. I am the more anxious as the work is unquestionably *much wanted*, and the sooner his subscription list has closed, the sooner it will be published. Dr. Mayne, I know has, from conscientious motives, refrained from announcing his intended publication until he had all the materials ready for its completion. Such being the case, the subscribers may rely with confidence on the regular issue of each part on the day fixed for its appearance.

I remain, your obedient Servant,
THOMAS SMITH, M.D.

Cheltenham, Sept. 20, 1851.

THE MEDICAL BENEVOLENT COLLEGE.

To the Editors of the Provincial Medical and Surgical Journal.

GENTLEMEN,—Mr. Bottomley tells us that he, "with many others," refrains from attaching his name to the list of subscribers *at present*, until they "see the Committee a little more scrupulous about admitting medical subscribers who practise irregularly." But the Committee have no option in the matter. Subscriptions transmitted to them become at once the property of the College, which they, as Trustees, are bound to appropriate accordingly. They have no moral right or legal power to refuse or return them, on any pretext whatever. If they did so they would become guilty of a violation of good faith, which gentlemen so sensitive to right and wrong as Mr. Bottomley and his friends are, could scarcely be expected to overlook. I would beg to suggest to your correspondent, who seems really interested in Mr. Propert's undertaking, that the subscribers at present are not too many, but too few; and that, as he is not only an orthodox practitioner, but a man of influence, the best way to purify the list would be to *grace* it with his own name and those of his many friends. We shall hope to see the list of Croydon subscribers very numerous, especially as many whom Mr. Bottomley has solicited to belong to the *Surrey Benevolent Fund* have declined to do so, and can, therefore, the better afford to support the Medical Benevolent College.

I am, Gentlemen, your obedient Servant,
NO COMMITTEE-MAN,
BUT AN ORTHODOX PRACTITIONER.

Sept. 8, 1851.

Medical Intelligence.

THE CREWKERNE AND YEOVIL DISTRICT MEDICAL ASSOCIATION.

This Association held its second general meeting at Yeovil, on the 11th inst., and many of the medical gentlemen of the neighbourhood attended. Although in existence a few month's only, this society has done a great deal of good, and numbers seventeen members, all of whom engage actively in its support. It offers considerable advantages, and we hope it will continue to uphold the dignity of the profession and that unanimity among its members which is so desirable in this season of heresy and schism. Since its formation, it has declared that those Insurance Offices which do not remunerate the medical referee for his faithful report of the state of his patients' health, to be unworthy of the support of the profession. Active measures are also being taken to prevent the growing injury inflicted upon medical practitioners by so-called benefit clubs and friendly societies, which receive, as members, many respectable tradesmen, whose sole object in entering is to obtain attendance for the small contract payment of from three to six shillings annually. It has brought to light several instances of the inhuman policy adopted by the Poor-Law Board and its satellites, the Guardians. It now calls attention to irregular practice and the gross ignorance, or wilful perjury of many quacks of the present day, and urges on our Colleges the necessity of protecting the public by withdrawing the sanction obtained by the possession of their diploma, in order to expose their apostacy. The members announce their intention to avoid all intercourse with any of the tribe

of empirics. There is little doubt but that an Association commenced in such an excellent spirit, and composed of respectable and respected practitioners, must be of great benefit to the profession and to the public; and we hope that their brethren will in every way give them their willing support.

EPIDEMIOLOGICAL SOCIETY.—INQUIRY ON VACCINATION AND SMALL-POX.

Notice to Members.—We are requested to inform our readers that the above inquiry will shortly be brought to an issue, and it is hoped that those members of the Association who have not already replied to the printed queries, will forward their replies to the Honorary Secretaries of the Epidemiological Society, 38, Berners Street, before the 15th of October next.

This Society has appointed an Epizootic Committee, which held its first meeting at Mr. Tucker's residence, on the 19th of August. Professor Simonds is appointed chairman.

FELLOWSHIP OF THE COLLEGE OF SURGEONS.

The following were the questions submitted at the last examination, on anatomy and physiology:—

1. Describe the knee joint, its articular surfaces and their form, the ligaments connecting the bones, the muscular attachments serving the purpose of ligaments to this joint, other muscles or their tendons passing over the joint.

2. Describe the parts seen on opening the abdomen, and their relative position. Describe the formation, extent and attachments of the great and little omentum, the peculiar charactars of the small and large intestines, and the special circumstances distinguishing the duodenum.

3. Describe the membranes which invest the brain, the peculiarities of their structure and function. The remarkable circumstances distinguishing the arterial and venous apparatus of the brain from those of the other parts of the body.

4. Describe the boundaries of the peritoneum, the parts contained within it, and their relations to each other.

3. Describe the parts exposed in dissecting the bend of the elbow, and their relative position.

6. Describe the circulation of the blood through the heart and lungs, with the action of the valves. Also the changes effected on the blood in its passage through the lungs, and in the general circulation.

The following on surgery and pathology were submitted on the 6th inst.:—

1. State the primary and secondary consequences of a wound into a joint, if adhesion of the divided parts do not speedily take place. Describe the treatment of such wound, and of its consequences.

2. Describe the symptoms and causes of a strangulated hernia. The treatment to be employed for its reduction. If an operation be required, what is its object, and what the circumstances which determine the return or not of the contents of the sac into the abdomen.

3. Describe the symptoms distinguishing concussion and compression of the brain. The kinds of compression, and the periods at which the symptoms appear. State the treatment of concussion and its effects, and generally that of the several kinds of compression.

4. Describe the causes and treatment of retention of urine from stricture. Also, the causes, consequence, and treatment of extravasatian of urine.

5. Describe the primary treatment of a wound made into the brachial artery in the operation of phlebotomy. State what happens to the artery if improperly treated on the occurrence of the accident, and what is then to be done under such circumstances.

6. Describe the consequences and treatment of a penetrating wound of the lungs.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a special court held on the 13th instant, Mr. Leslie Ogilby Patterson, of Downham Market, Norfolk, passed his examination, and obtained his diploma.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, Sept. 11, 1851:—George Earle, Beverley; Henry Folkard, Old Brompton; Henry Lowndes, Liverpool; Wm. Notley, Manchester; Thomas Wynne Williams, Denbigh.

OBITUARY.

September 2nd, at his residence, Chelmsford, John Carr Badeley, M.D. The deceased was a member of the Provincial Medical and Surgical Association, and well known to his professional brethren as an accomplished and talented physician. He delivered the Harveian Oration last year at the College of Physicians.

Lately, at Oxford, J. Kidd, M.D., F.R.S.. Regius Professor of Physic in the University of Oxford. There are circumstances connected with the interest taken by Dr. Kidd in the Provincial Medical and Surgical Association, which demand a more extended notice in our next number.

At his residence, Forston, George Peacock Button, M.D., Superintendent of the County Lunatic Asylum, Forston, near Dorchester.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, September, 1851.

TO CORRESPONDENTS.

Communications have been received from Mr. Harvey, Dr. Edwards, Mr. Hunt, Dr. Ogier Ward, and Mr. Bree.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., Edin.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

[Reported by MR. HENRY GREEN, Student.]

LECTURE IX.

On the Morbid Conditions of the Circulating Tubes.

Gentlemen,—We have next to direct our attention to the affections of the circulating tubes, including the arteries, veins, and absorbent vessels. These affections either consist of inflammations and alterations of structure, or degenerations. My observations will necessarily be brief, as a great many of them rather come under surgical than medical treatment.

Arteritis has not yet been sufficiently studied and ascertained to be admitted as a regular disease into all books treating of physic. Nevertheless, we know that arteries may become inflamed, as well as other parts of the body, and therefore must recognise the affection, whether it be common or not. Certain pathologists, as you may be aware, have asserted that the original cause of all simple inflammatory fevers is nothing more nor less than an idiopathic arteritis. I have never had patients with simple inflammatory fever so violent as to cause death; and, therefore, have never had a personal opportunity of confirming or comfuting such a view of fever, by *post-mortem* inspections. But, nevertheless, I shall have no hesitation in offering my abstract views on the subject, based upon principles of general pathology. I shall and must admit that, if irritating matters were circulating in the general current of the blood, they *might* give rise to a general inflammation of the arteries; and that the consequence *might* be an effusion of fibrinous lymph, which would tend to block up the channels of the capillary circulation, and so induce that arrest of the secretions which is a main feature in fever. But, on the other hand, we must also perceive that, if such irritating matters subsequently induce all the other symptoms of a fever which shall run through its regular and definite courses, not in reference to any local inflammation, but solely in reference to the continuance of such poison in the blood, then the arteritis (*if it do exist*) is no more the cause of such fever than is the previous headache or shivering, but simply one of the many sequences that will follow upon the transfusion of a ferment or other morbid essence into the system. As we cannot admit that any inflammation, throughout the *whole extent of the arteries* could arise, except through the agency of the *whole mass of blood;* and as it is not the office of natural blood to excite inflammation, the conclusion as to the presence of some foreign matter in such a case is absolutely inevitable. But, further, if the fever that supervened were merely symptomatic of the local affection, its course would be very irregular, and subject exactly to such variations as characterise a local inflammation; whereas the marches of such fevers are found to be pretty uniform, and therefore not very consistent with the uncertain progress of any local inflammation. Hence, as you will see, I do not adopt the idea of arteritis being the primary cause of inflammatory fever, or even its necessary concomitant. Nevertheless, should any patients die in the stages of a simple synocha, or in the first stage of synochus, I shall not fail to examine the arterial coats, with the special view of testing these speculations. But, although I neither admit nor deny the existence of an universal arteritis, I entertain no doubt whatever of a limited inflammation of the internal and middle membranes. The softening, wasting, and ultimate ulceration that precede the formation of an aneurismal tumour, leave no doubt of this fact. Such tumour may, certainly, occur in consequence of simple mollification of all the three coats of the artery; but, most commonly, it arises from the destruction of the two inner ones, and a distension of the external investment. This accident usually takes place at some sudden turn or bend of a large vessel, where the current of the blood, meeting with sudden resistance and repulsion, is most apt to exert such force as may induce this lesion of structure. Hence it is most common at the arch of the aorta and in the popliteal artery, amongst those persons who are liable to maintain a constrained flexure of the lower extremity for several consecutive hours in each day. As the latter comes under surgical treatment, I shall make no further comment on it, beyond the mention of the ascertained fact, that in all cases there is found not merely a limited pouch, but also the existence of diseased and mollified artery for a considerable space beyond the tumour; hence rendering it more prudent to stop the flow of blood by ligature on the femoral artery than on any portion of the vessel near the seat of disease, as in the latter attempt the coats will most likely give way, and the person die of hæmorrhage. Aneurism of the aorta is purely a case for the physician, and in its early stages is very difficult of discovery. As may be inferred from physiological probability, the arch is the most frequent seat of the disease, on account of the great body and impulse of the blood that starts up against it at every beat of the heart, and the proportionate repulsion that takes place at the moment of concussion. If any arteritis exist at all, this is very likely to be its chief seat, propagated, as it may be, after the manner of an erysipelas, from the endocardial linings, either under rheumatism or other form of retained excretion. At first there will only be a little roughness, perhaps not sufficient to give rise to any sound. Nay, even before any sound is apparent there may take place a certain amount of difficulty of swallowing, or other evidence of physical obstruction, along with distinct projection of the ribs to the right of the sternum, as in Charlton and Wells.

Mary Ann Charlton had been for a considerable time

the victim of rheumatism in the spine, &c., but got cured of that in the hospital. In the course of treatment she had also a severe attack of pericarditis, with very rapid pulse, friction-murmurs, and total inability to lie on either side. On the subduction of these symptoms, no morbid sound remained about the heart; but a bulging was observed on the upper part of the sternum, with a very faint sighing sound, like that in a small sea-shell, heard at each contraction over the right clavicle. The pulse, at the same time, was recurrent, and easily compressed, beating habitually from 120 to 140. The diagnosis formed was, that there was dilatation of the arch of the aorta, whatever else existed, and the sounds, at first scarcely perceptible, have ever since been growing louder and louder, so that she is now seen regularly in the physician's room as an out-patient, affording illustrations to the gentlemen present of such arterial sounds, as they are so loud and rough that the veriest tyro cannot but recognise them. She is constantly liable, under any exertion or exposure, to be troubled with cough and dyspnœa, rheumatism, &c., but yet, with proper care, and the habitual use of digitalis and iron, she has, upon the whole, been kept tolerably comfortable for nearly the last eighteen months.

Ann Wells, aged 23, an out-patient; was pale and thin. She had slight cough, with dyspnœa, and complained of oppressive fatigue and shortness of breath under the slightest exertion, and was troubled with little boils, strumous swellings, sweatings, and other accompaniments of a languid and vitiated circulation. Her pulse was 120 to 130, recurrent, and readily compressed; and the respirations were 32, but the heart's sounds natural. Though, with the aspect of a consumptive habit, the pulmonary sounds were good, and indeed she too soon lost her cough, &c., to permit the diagnosis of pulmonary phthisis. A bulging, however, was discovered at the upper part, and to the right of the sternum, which suffered some pain under pressure. A blowing sound was likewise discovered there, propagated upwards over the right clavicle. Dilatation of the arch of the aorta was suspected. Some leeches were applied, and, bearing in mind her general habit of body, she took digitalis and muriated iron, along with cod-liver oil. Under a course of this kind, her boils and strumous swellings, &c., disappeared, her pulse descended to 80, and her respirations to 20, and the blowing sounds became more soft and easy. The murmurs had not disappeared when she last ceased in her attendance at the hospital, but she suffered no very appreciable inconvenience, and was, therefore, only enjoined to live carefully, and avoid all excitement, or any great exertion of body or mind. She has twice been under our treatment, and twice got better.

It is to be admitted, that in neither of the above cases has any demonstrable verification occurred, inasmuch as the patients are still alive; but the facts stated with respect to both, certainly offer *primâ facie* reasons for believing in the presence of dilatation and roughness at the arch of the aorta, if not of actual aneurism, in an incipient stage. In each of them it is to be observed that the sounds first discovered were of a very faint and obscure character; so much so that they were not perceived, even under repeated attempts, by inexperienced ears; nor would I have permitted my own perceptions to lead me into any positive assertion of the existence of these faint breathings of morbid action, unless they had been confirmed a week or two afterwards by sounds so distinct and persistent as to remove all doubt.

The statement of this fact simply proves that something is to be gained by constant practice, irrespective of the perfection of hearing, that must necessarily belongs to the young, and that it is only by long persevering diligence, and studied nicety of aural perception, that any one can become a good stethoscopist. And here I would remind you, as a plain and practical fact, that if you would preserve your ears in good condition, you will not remove from them the natural protection of the hair. By this shield from the effects of damp and cold, you may be able to maintain them intact to the end of life; whereas, their open exposure to all the vicissitudes of the weather and to the invasion of loud stunning sounds, may induce disorders, which will end in dulness of hearing, if not in positive deafness.

This deficiency of hearing is a great evil to any one, but more especially to the physician, considering the very many serious ailments to which that faculty affords him the principal clue. Aneurism is one of those diseases. The sound may be double or single, or, when the tumour is very large, it may almost be a continuous hum. This arises from the roughness of the walls, and from the body of blood contained within the sac. While it is yet in the process of commencing growth, there must be a certain amount of roughness, on account of the lesion of continuity in the walls of the vessel; and afterwards, as the cavern expands, and becomes filled with coat upon coat of coagulated stagnant blood, the sounds must of necessity become louder and louder. In the cases now cited, the sounds were heard most distinctly above the right clavicle, and a little below it, though not at all over the aortic valves. At the same time there was irregularity of the pulses at the wrist, some difficulty of deglutition, protrusion of the superincumbent bones, and general constitutional uneasiness, from inefficiency of the circulation. In another of these cases, viz., that of Harrison the blacksmith, suffering from hypertrophy, we have had similar symptoms; but coupled with the systolic blowing, there also arises, from time to time, a continuous musical sound, like that of the shrill hum of a small gnat within a flower cup, the source of which appears to me very dubious. The only treatment that can be pursued, is to moderate the force of the circulation, and to enjoin quietude of mind and body. Under such management, it is possible that the hollow may be filled up by successive coagulations of the contained fluid; otherwise, and most commonly, it goes on increasing, and causing by its pressure, the absorption of all surrounding structures, even including bone, till at length, nothing being left to offer any solid resistance to the perpetual wave upon wave of blood, excepting the accidental and scarcely organizable coagula of the tumour itself, these ulti-

mately soften and give way, and the patient suddenly dies by a gush of arterial hæmorrhage. You had, sometime ago, an excellent example of this fatal conclusion, in a case not belonging to me, in the top ward of the the Adelaide wing, after a protracted lingering, when the sac proved to be about as large as a child's head.

PHLEBITIS is by no means an uncommon disease, and is a particularly serious one, as the morbid discharges from the inflamed venous coat are at once carried to the centre of the circulation, sometimes in great volume, when they set up all the symptoms of a general depressant fever. This species of inflammation may be excited by a puncture, or, at least, the introduction of some irritant poison, such as putrid animal matter, &c.; or it may be propagated from some seat of extensive injury and inflammation along the serous surfaces of the traversing veins, soon involving not only these, but all the other channels through which the poisoned blood passes. All this is illustrated by dissection-punctures, wounds from a foul lancet, or absorption of pus from an injured limb, or from the abraded uterus. In a minor degree it induces what may be called purulent hectic, with rapid small pulse, and delirium—a not unfrequent occurrence after surgical accidents, or in the last stages of peritonitis, pneumonia, or phthisis. Perhaps the worst and most depressant form of this symptomatic febrile manifestation, however, is that disease called puerperal fever, proceeding from an inflammation of the veins and other absorbents of the uterus, transmitted from the denuded surface of that organ along the numerous vessels bound inwards. Pus is often elaborated in this case to a vast amount, and it is always found to proceed from the application of an animal poison to the abraded surface, most commonly introduced from without, as in crowded and mismanaged hospitals, or by infection from impure hands; but yet, in idiopathic cases, decidedly proceeding from some irritating matter eliminated from the patient's own body—an idea very readily understood when we consider what offensive elements may be retained after labour, to react on the tender surfaces of the womb.

As this disease, however, belongs to a particular province of the profession, and, as the consequence of the absorption of pus will be treated of again and again under other inflammations, as well as under the morbid conditions of the blood, I need not detain you with further observations on this point beyond saying that the great principles of treatment will consist in arresting the inward progress of the purulent secretion, both by compression (if practicable) and evacuation, and subduing the inflammatory action by such general remedies as have already been recounted, as leeching over the seat of inflammation, with calomel and tartrate of antimony, in the early or inflammatory stage, but giving stimulants under that depression of the organic life, which is apt to follow in this disease, as in external erysipelas. While upon the subject of the absorption of pus, I may remind you that one of the worst terminations of phthisis is delirium, apparently due to the presence of pus in the last stage of that disease. This symptom must be very painful to all, but more especially to the relatives of the sufferer, who are thus debarred from those last acts and words of tenderness, (not to speak of more important considerations,) which go so far to cheer and sanctify the bed of death. No phthisical patient of mine has ever died in this hospital under delirium, and I attribute this result entirely to the subduction of inflammation by blisters, or other counter irritants.

The PHOSPHO-CALCAREOUS DEGENERATIONS that are apt to overtake arteries, have already been discussed while we were speaking of valvular diseases, and, therefore, it is unnecessary to occupy our time now, either with the nature, causes, or treatment of arterial calcification when not very extended; and the only form of this ailment which I shall mention further, is that of senile gangrene, as it has been called. SENILE GANGRENE however, is not an accurate appellation. It is true that it is generally in the aged that the powers of the heart become so feeble, while the general structures of the body get so indurated or degenerated, that they become, in a special manner, liable to this form of disease; nevertheless, it will happen that younger men shall be attacked by this calciform degeneration of the arteries, and gangrene supervene in them as in the old subject. We may also have similar results from a fatty degeneration, as in the case of Thomas, which is so interesting a one that I shall state its history, as officially recorded in the ward-book.

This patient stated that he had had active service as a soldier for ten years, and had often worked long in the trenches. He had left the army on account of a fracture of his right leg, since which he had become corpulent, though without any positive complaint. Eight months ago he had an attack of severe pain in his right arm, which was followed, or accompanied by, a diminution of its muscular power, and a loss of impulse in the radial artery, so that the arm became quite fatigued by merely driving in a few garden nails. About one month thereafter the right leg became affected with weakness in like manner, and on the day of admission he had, while walking in the street, first felt a numbness creep from the foot upwards. He fell down and was carried to the hospital. On admission he lay prostrate and exhausted in bed, the heart's action was feeble and intermittent, and no pulses were felt, but after a time he rallied a little, so that the heart beat regularly sixty in the minute; while the pulse returned to the left side but not to the right. He had some tremulousness, but no particular pain. His breath was very offensive and his tongue thickly furred; his right arm was colder than his left, and both lower extremities, though fully developed, were cold. He had scarcely any power in his feet, the face was full, but pale and tallowy. The diagnosis first formed, was, that there was paralysis, afterwards constitutional gangrene was apparent, and fatty heart was suspected. The treatment for the paralysis consisted, at first, of hot frictions, with purgatives and ammonia. When the gangrene became obvious at the toes, emollient cataplasms were applied, and he continued the ammonia, with other tonics, and wine. Under this course he seemed to improve, as the

tongue, from black, became red, and the sloughs proceeded to separate, having a healthy looking margin at the living parts. Unfortunately, however, he subsequently caught severe and extensive erysipelas from another man in the ward, which involved the whole of the right leg, a deep burrowiug ulceration set in, and the house-surgeon, Mr. Moore, had to evacuate the matter by long incisions. For several months he lingered in this state and then died in coma. After death the heart was found large, flabby, and pale. Nothing particular was found in the radial or femoral arteries, except that they seemed narrower and softer than usual; but the popliteal of the right leg was obliterated at its bifurcation, and the anterior tibial was a solid chord, all vestige of which was soon lost in the debris of the ulcerated parts. The whole of the muscular tissue of the limb was reduced to a state of fatty degeneration, so that it cut like stale white fish, rather than red animal flesh, and at every incision there exuded a profuse discharge of thick colourless fluids, largely charged with oil. No phosphatic deposits were anywhere observed, and I adduce this case as one which simulated, in a great degree, the calcareous degeneration of which I have been treating.

It will be observed in the case just recited, that the pulses were absent in the most affected side ever since an old attack, and that the ultimate ailment came on with a sense of cold and numbness. At last muscular power was lost, the patient fell down, brown spots appeared on the foot, his tongue was brown, acute local pains occurred, and his toes gradually disappeared, yet he was a large, stout, hale-looking man, and not above 45 years of age, though he looked 60. The treatment of the case was at length partly surgical, but, inasmuch as he entered the hospital with paralysis, and as that and all his subsequent ailments proceeded from a constitutional source, it could not have been justifiable to have employed any strictly surgical appliances while there were any hopes of a constitutional treatment arresting or impeding the progress of the disease. The result was, that the man first lost four toes and part of the cushion of his heel, but had amputation been performed when the line of demarcation became distinct, I think it highly probable, or indeed I may say it is certain, that a defective reaction would have occurred at the stump, and so rendered amputation upon amputation necessary, until we had come to the hip-joint, as was illustrated also in the case of a certain major, about which there was a serious plea in law some fourteen years ago. Without a reference to the printed cause, I cannot charge my memory with the minute particulars, suffice it to say, this gallant major had the misfortune to be attacked with gangrene of the toes like this man Thomas, who was also an old soldier. The family surgeon who attended him employed local stimulants, which greatly augmented the pain, without stopping the gangrene. He next amputated the parts, but the old action, or rather *defect of action*, set in again; outward applications once more failed, and again and again these exciting agents and amputations were resorted to, until there was nothing more to amputate, and death cut the matter short. On this event the gentleman rendered a bill of £750. The executors of the major disputed this, and, if two great surgical authorities had not differed on a certain point, very probably the jury might have given a very disagreeable verdict in the matter; however, while Mr. Lawrence declared for the emollient, soothing, and yet tonic treatment adopted in our case, Mr. Liston as strongly gave evidence in favour of local stimulants and heroic amputation, as in that of the major. Under such high conflicting testimony, no judge or jury could venture to be very decisive; they took, however, a medium course, and cut down the remuneration to £500. I am decidedly of opinion that, under all such circumstances you must seek to soothe irritation, and abate inflammatory action, otherwise, by fibrinous lymph blocking up the vascular channels, and by want of sleep, and exhaustion of nervous energy, the local death must go on increasing. If the parts are maintained in free circulation, it is only to be accomplished by the mild application of heat, as in poultices, and by the support of the internal energies by means of those diets and medicines which are recognised as tonics, and diffusive stimulants, never by those that only excite a temporary exaltation, which is sure to be followed by corresponding depression. The wine, &c., here given, was doled out in very small quantities at short intervals, so as to effect a sustained tonicity. To have given large doses at long intervals, could not have failed to be hurtful. As to local stimulants, they would have increased inflammation, and harassed him beyond expression; while, as respects amputation, every inch of his flesh that might remain, would be a living evidence against its expediency, independently of the very decided opinions that have been expressed by Pott, Sir Astley Cooper, and others. The *post-mortem* appearances verified the opinion as to the constitutional origin of the disease.

Similar inflammations and degenerations may take place in the absorbent vessels, and with similar constitutional results, though certainly less severe. Inflammation, leading to obstruction and enlargement, does thus arise in an acute form, from the application of various irritant poisons, as in the minor instances of petty stings, or the revulsion of natural excretions, and in the greater ones of syphilitic and other more acrimonious matters, in which we witness the regular advance of inflammation along the line of the absorbent canals, and its augmentation at every congeries of these tubes in the conglomerate glands. This process is so completely illustrated by the familiar instances of the painful swelling of the lymphatics of the head, the neck, and the groin, that I need not enter into any particular discussion of it, suffice it to say that our object must be, to remove or neutralise the irritant cause, abate inflammation, and promote absorption of the effused fluids.

The means of neutralizing irritants must, of course, be as various as the varied nature of these agents. Most of them are of some acid tendency, and therefore the application of alkalies is very generally serviceable in the first stage. Should they be alkaline however, oils or acids might be of service, and, if simply putrid, antiseptics, such as acetic or muriatic acids, or

chlorine would prove of some avail. But many are specific and require specific remedies, as in the cases of the morbid poisons. Thus mercury will neutralize the virus of syphilis, vaccine lymph will counteract variolous matter, and sulphur that of the itch; and it will be well for us, when we can add to the number of such certain facts, so as to contend against typhus, scarlatina, or cholera, with success. The local inflammation is to be treated in the same manner as phlebitis, and absorption is to be promoted by the application of heat, and such discutients as camphor, iodine, or mercury, or ammoniacum.

The chronic enlargements which occur in the lymphatic and other superficial glands in the scrofulous, with depositions of tubercular or suborganized granular matter is of a nature very different, at least from acute inflammation; though this may supervene afterwards, under the irritating pressure of the accumulated deposits. They are very apt to occur in the strumous habit, whenever it becomes exposed to cold, or to a continued poor diet with confinement. Thus they are most common among the poor, in prisons and workhouses. We know that, under such circumstances, the absorbents are most active on the living structures of the body, and therefore the least organized portions of the frame are likely to find their way in greatest abundance into the lymphatics. There, therefore, appears to be an occasional accumulation of tuberculous matter in the larger receptacles of that system, which is well understood as the ordinary form of struma, and into the scientific theory of which I shall enter when we come to treat of the morbid condition of the blood and of the ganglionic innervation. You have had many opportunities of observing this morbid condition in the Queen's Hospital, and how readily it may sometimes be subdued by sound nourishment, and free air, along with iodine and cod-liver oil, with iron and phosphate of lime; but the cases are too numerous to be recited. Although mercury is almost universally used in the strumous affections of childhood, a certain prejudice has sprang up against its employment in the same cases in after life, as being dangerous in the extreme. I do not see any sufficient grounds for such a supposition. Doubtless, the manner in which mercury was wont, in former times, to be employed by certain parties, must have weakened the general system, and so increased the disease; and the exception made in favour of children was simply due to the fact that they are less liable to the peculiar effects of that metal than adults. But I can have do doubt that, if judiciously employed, merely as an alterative, and not as a salivant, mercury is just as useful for the struma of the adult as of the child. Indeed the fact has been demonstrated here by the very successful results that have been witnessed from the iodine and mercurial ointment, as well as the mercurial plasters, which have first subdued the inflammation, (when that has happened to supervene.) and next caused the disappearance of the tumour. A very great object is to avoid deformity from the ulceration of these swellings, especially about the neck, and therefore every means that can be devised for discussing the tumours, such as leeches, mercury, iodine, ammoniacum, and the like, should be promptly applied. The ferruginated cod-liver oil, is more a preventive perhaps, than a discutient, and acts after the manner of an improved diet. When irritability exists, sedatives must also be used, especially conium. To sum up, the treatment I generally adopt, and with perfect success, is as follows:—To abate inflammation when present, and to soften the induration by local abstractions of blood, poulticing, and the exhibition of mercury either internally or externally; next, to promote absorption and sooth irritation by such a combination as iodide of potassium and conium; and lastly, to prevent further degenerative action, by tonics, nutrients, fresh air, and all the other adjuncts of the tonic regimen. Such a degenerative action has a constant tendency to recur, and must be as constantly combatted by dietetic regulations. We must, therefore, enjoin a liberal use of albuminous food, and from time to time aid the formation of a proper plasma, by the exhibition of oil, iron, and the calcareous phosphates.

ON ARTHRITIC HEADACHE.

By WILLIAM HARVEY, Esq.,

SURGEON TO THE ROYAL DISPENSARY FOR DISEASES OF THE EAR.

In my former papers on rheumatic inflammation of the ear, I observed that the headache and distressing noises succeeded as a consequence of the attack on that organ. In the arthritic variety, however, this is not the case, the head becomes affected for some time prior to its manifesting any disturbance in the ear, and as the symptoms are often very much mistaken, I have thought it essentially necessary to direct attention to their early character; I shall have occasion, however, to allude to some cases which will immediately follow this paper, wherein the ear becomes the seat of mischief from the first. The noises and benumbed sensation of the head, accompanied with intermittent hemicrania, neuralgia of the facial nerves, pains affecting the eyeballs, the ears, the fauces, the teeth, and the lumbar regions, are all premonitory of this diseased condition. I have, in some instances, witnessed for days, the tonsils so sharply seized with gout, as in the absence of any considerable degree of inflammation and careful history, to question for a time the fact; it sooner or later, however, is explained by a seisure of gout, which solves the mystery. When it attacks the ear, the lobe is generally the part, becoming swollen, intensely red, and exquisitely painful, lasting for days and sometimes weeks, attended with deep and distressing noises, referred to the interior of the head. Dr. Holland observes, that it is somewhat difficult to class the several forms of intermittent headache with other affections of this kind, but those having lengthened periods of intermission, may perhaps, best be noted here. The equality of time often observed, even where the intervals extend to two or three weeks, or yet

longer, is a very remarkable feature in these cases, and denotes a cause, specific in its nature and uniform in its operation. I know instances where such intermittent headaches have occurred during the greater part of a protracted life; more frequently, however, it happens that they affect especially certain periods of life, in this, as in many other circumstances, showing singular relation to various disordered actions of the gouty constitution. In conformity with the same relation, there is reason to believe that the kidneys are the excretory organ most concerned in giving relief in these cases, and principally by an increased separation of lithic acid, or its salts. Such action may readily escape notice where the attention is directed by the presence of pain to another part, but I infer it on close observation of many intermittent headaches, and think the remark likely to be confirmed by others.

Gouty affections of the head constitute one of the most dangerous and most formidable varieties of disease, dependent on or caused by arthritic diathesis. Gout in the head, as it is popularly termed, may be met with either in the form of arthritic headache, or of arthritic apoplexy. The former, indeed, is often the precursor of the latter, and not unfrequently, when it has been mistaken and consequently maltreated, ends in it.

Arthritic headache is a disease that often escapes detection, especially if the patient has not previously had a paroxysm of gout in its regular form, so as to aid the judgment of the practitioner in forming a diagnosis. The symptoms which mark the disease, are attributed to an ordinary determination of blood to the head, or rather to the brain, and the treatment is in accordance with such views. A greater mistake could hardly be committed, for all depletory measures in the treatment of gouty affections of the brain and its membranes are injurious, yet such constitute the principal remedies employed to relieve the consequences of determination of blood to the brain. As it is very generally, although not always, that the head, and subsequently the ear, become affected by the metastatic action of gout, I cannot better allude to the subject as a confirmation of my own views, than by quoting the forcible and clear description given of it, by Dr. Gairdner. He observes :—"That metastasis to the head appears by far the most usual of misplaced gout. It occurs with every degree of suffering The headaches from which those persons suffer, in whom the excretions of urates and urea have, from any cause, been suddenly diminished or temporarily arrested, are only a commencement of this affection, which may well be likened to the effect of a poison. I believe that the substance of the brain itself is the part usually affected in these cases, and my reasons are, that they are never attended with delirium or wandering, but always accompanied by stupor or apoplexy, the ruptured vessel is found in the cerebral substance. It has been said that such cases are to be treated like apoplexy from any other cause. I am quite satisfied that this information is most dangerous. Patients affected with gout in the head do not bear the abstraction of large quantities of blood. Much regard must be had to the heart, which is always more or less diseased, and sometimes in an advanced state of disorganization. We may easily and quickly relieve the worst head symptoms; but if the relief afforded be not meted out with wariness and skill, we shall too surely discover that we have fastened on our patient worse and more hopeless evils. The abstraction of much blood is, however, wholly unnecessary. A relief given to the system by a small bleeding, will enable the kidneys to resume their office, and the worst symptoms will then safely depart."

In these cases colchicum is a most useful remedy. I have mentioned the discovery of Chelius, Maclagan, and Servius, that it greatly increases the secretion of urea. The application of this fact to the case in hand, must be obvious to all, and the effects of the medicine will fully answer their expectation; but here, too, I would insist on the propriety of using minute doses of the remedy, which more safely and not less effectually, than larger ones, accomplish the objects in view. Laxatives in head cases are always necessary; and even drastic purgatives may be required. Prudence, however, is indispensable in their use; for while no constipation is permitted which would urge the blood to the head, regard must be had to the patient's shattered condition. Precise rules cannot be laid down; but the experienced physician will hardly err, if he do not lose sight of the impaired condition of the circulation, at present labouring under a double disadvantage from the oppressed state of the brain, in addition to disease of the central organ."

Arthritic headache, then, is a disease which demands considerable discrimination and close observation to detect, based on the information obtained by extensive experience, as it is only by distinctive signs, which, by some may be regarded as apparently trivial, that we shall be enabled to determine the true nature of the attack.

It occurs generally among those in whom gout fails to show itself in the ordinary way, but remains lurking in the system ready to pounce upon any organ which, by fortuitous circumstances, may be liable to take on diseased action. The higher classes of the community, among whom gout is frequently an heir-loom being in many instances transmitted by both parents, are far more liable to this form of metastatic gout than are either the members of the middle or of the lower orders of society. It is, likewise, found more readily to affect the females of a gouty family than the males, and more frequently after certain periods of life have been reached. The younger members, and the male branches, do not meet with absolute immunity from arthritic headaches, but they are much less subject to attacks.

The symptoms which are not pathognomonic of this disease are,—a sense of fulness in the head, generally constant, but liable occasionally, from casual circumstances, to change into severe pain; a feeling of vertigo or giddiness, and as if a movement were occurring in the head—a feeling to which the attention of the patient is continually drawn, and which, apparently, impairs the power of thought and of memory; all the perceptions

are confused, and the patient at the same time experiences a sensation as if he were about to become insensible. If he stoops, he is apt to be seized with temporary blindness, the hearing is inordinate'y acute, the least noise rendering him almost distracted; he is frequently troubled with a buzzing sound, and sometimes with other noises in the ears; flushings and heat pass at times over the head and face; the hair is often tender and painful when touched, and the scalp feels hot, constricted, and uneasy. With respect to the general symptoms which attend upon this state, they are such as indicate a disordered condition of the digestive apparatus, and an ill-regulated and badly-formed secretion.

The function of digestion is most frequently very imperfectly performed; flatulence, with acid eructations; a sense of weight and general uneasiness at the pit of the stomach; rumbling in the bowels; an unpleasant acid or bitter taste in the mouth; the tongue furred with a brown fur, with occasional yellow streaks; a disordered state of the bowels, which are sometimes confined and at others much relaxed, the stools being generally clay-coloured, shewing a deficiency of bile, or else very high-coloured, dark, and offensive, showing a redundancy of that excretion, but in a very unhealthy state; the urine unusually scanty, and high coloured, and depositing a reddish sediment on standing, with a rough dry skin, are symptoms which indicate a general disarrangement, and an imperfect performance of the ordinary functions of the body, by which the effete matter of the frame is got rid of by means of the secretions and excretions, and fresh pabulum or material furnished to supply the waste of the system. Meanwhile, in the midst of much disorder of the secretive apparatus, the pulse generally remains undisturbed, or, if at all altered, shows a diminished rate of circulation, —a lessened degree of tone in the system.

The symptoms are those that are found to be placed almost beyond the possibility of a doubt. It is the result, I conceive, of a morbid condition in the function of sanguification, or perhaps of the immediate preparatory process or chylification, by a failure on the part of the kidneys to perform rightly their secerning duties, by which the separation of urea and uric acid upon the blood should be effected. The presence of this acid in the circulating medium, then, may be regarded as characteristic of the gout, and the fact ascertained by Chelius, of Heidelburgh, that in the course of twelve days, under the administration of colchicum, the kidneys are excited to abstract from the blood nearly double the quantity of uric acid they had previously separated, will amply serve to explain the remedial influence of colchicum in the relief of the disease, and the manner in which the influence is excited.

2, Soho Square.

[To be continued.]

ON THE PROGRESS OF PUBLIC HYGIÈNE AND SANITARY LEGISLATION IN ENGLAND,

AND THE ADVANTAGES TO BE DERIVED FROM THEIR FURTHER EXTENSION.*

By J. INGHAM IKIN, Esq.,

Fellow of the Royal College of Surgeons of England, and Lecturer on Anatomy and Physiology in the Leeds School of Medicine, etc.

Read before the Leeds Philosophical Society, March, 1851.

In March, 1842,† a Select Committee was appointed to consider the expediency of framing some legislative enactment to remedy the evils arising from the interment of bodies within the precincts of large towns, or of places densely populated. Mr. Mackinnon took the lead in this inquiry, and our member Mr. Beckett, was an active member of the Committee. The result of this inquiry, and of the mass of evidence given, showing the injurious and pernicious results arising from this interment within towns, was the report "that the practice of interment within the precincts of large towns is injurious to the health of the inhabitants thereof, and frequently offensive to public decency; and that it was expedient to pass an Act of Parliament to prevent it, with some few exceptions." The other recommendations and particulars it is unnecessary to dwell upon. The construction of new cemeteries was one of the good results; and after some squabbling we succeeded in obtaining two large

* Continued from page 543.

† I append a list of local sanitary reports made to Government through the Poor-Law Commissioners* *before* the general inquiry by a Committee of the House of Commons in 1842:—

A report from Mr. Hodgson and a Committee of medical gentlemen of Birmingham on the sanitary condition of the labouring population of that town.—A report on the sanitary condition of the dwellings of the labouring classes, &c., in Manchester, from Dr. Baron Howard, Physician to the Ardwick and Ancoats Dispensary of that town.—Also one on the condition of the labouring population in Liverpool, from Dr. Duncan.—One on the condition of the labouring population in Derby, from Dr. Barker. One on the condition of the labouring population of Truro, from Dr. Barham.—One on the condition of the labouring population of Brighton, from Dr. Jenks.—One on the sanitary condition of the labouring population in the town of Wolverhampton, by Dr. Dehane.—One on the prevalence of fever in the parish of Breadsall, Derbyshire, by Dr. Kennedy and Mr. Senior.—One on the sanitary state of the town of Stafford, by Dr. Edward Knight.—One on an improved condition of the town of Lancaster, by Dr. de Virtrié.—One on the sanitary condition of the town of Leeds, by Mr. Robert Baker.

Twelve reports from medical men on the sanitary state of towns and districts in Scotland, were appended also to this report of the Poor-Law Commissioners, besides many others from clergymen, magistrates, and other parties of local influence in different parts of the country; but it is quite impossible in a paper of this kind to enumerate all.

Two very recent publications connected with hygiène I must here, however, notice, as they contain many useful practical suggestions, and the author of them has given his attention to such matters for some years. One is a pamphlet "On the Contamination of Water by the Poison of Lead, and its effects on the Human Body," by James Bower Harrison, Esq., Surgeon, Manchester; and a recent letter of his to the Earl of Shaftesbury, containing "Suggestions as to the Expediency of Submitting certain Branches of Trade and Manufactures to Government Medical Inspection." Dr. Calvert Holland also has written ably on the injurious effects of grinding steel.

* "The Report to the Secretary of State from the Poor-Law Commissioners on an Inquiry into the Sanitary Condition of the Labouring population of Great Britain." This report, indeed, laid the foundation for Legislative interference with regard to the public health, and has proved invaluable. It should have been published in a cheap and abridged form.

and conveniently-situated cemeteries for our own town, besides those in the out townships. The exertions of Mr. Walker, regarding the exposure of the injurious effects of intramural interment in London, have been beyond all praise; and his work entitled "Gatherings from Grave Yards," did more than anything to rouse public feeling on this question. The question, as regards London, has not yet been satisfactorily settled, though in one of the latest reports on the subject, by the Board of Health, an adequate and satisfactory general scheme for extramural sepulture seems to be decided upon. But these reports we shall have to allude to directly, as they come last in order, and are of quite recent date. It was also in the year 1842 that the Leeds Improvement Act passed, and one also for Liverpool, in which latter town the mortality has always been high. These Acts were great steps in advance of most other towns, with regard to sanitary reform. But many of the clauses of the Leeds Act are scarcely efficient, so that the spirit of the Act does not seem always to be successfully carried into practice. Doubtless this will be remedied before long. But it is only due to the town in which we live, which all are so ready to run down and depreciate, on account of its smoke and dust, and in answer to the constantly-repeated charge of want of public spirit (which one must admit is not altogether ill founded) of its inhabitants, for me to state that Leeds is behind few large towns in the kingdom in some of the most essential requirements for the health and comfort of its inhabitants. Our sanitary charities are all excellent, viz., our Infirmary, House of Recovery, and Dispensary. Again, our School of Industry is a fine institution; our gaol,* unfortunately, is of national celebrity, and a model in its way. With regard to the grand desideratum—a good supply of water,—that we ought to have, for the price we have to pay for it. Our plan of sewerage, now carrying out, I hope will be as efficient as engineering skill can make it. Intramural interment is forbidden, with few exceptions, and our cemeteries only require plants, shrubs, and walks to render them very complete and appropriate receptacles for the dead. For relaxation we have our unrivalled moor. But what we want is a more general taste for architectural beauty and ornament, a better looking class of houses, public monuments, adequate town walks and promenades, and public buildings. Our market is much improved and enlarged. Fountains, and other improvements and embellishments, have been suggested. We are now getting a handsome class of churches and chapels, though much money has been thrown away in distasteful church and chapel architecture in this town. Still, looking at Leeds without prejudice, the place may be said to be like its inhabitants; it has considered first the useful—the ornamental and elegant are secondary considerations, to follow in due course.†

To return: the names included in the commission for inquiry into the state of large towns, are a sufficient guarantee that the inquiry would be an efficient one, and the report a practical as well as a scientific and correct one. Among the names we have Buccleugh, Lincoln, Slaney, Graham, De La Bèche, Lyon Playfair, Reid, Owen, Martin, Smith, Stephenson, Cubitt, &c. The principal points embraced in the commission, were "the causes of death among the inhabitants; the best means of promoting and securing the public health under the operation of the laws and regulations now in force, and the usages at present prevailing with regard to the drainage of lands; the erection, drainage, and ventilation of buildings; and the supply of water in such towns and districts, whether for the purposes of health, or for the better protection of property from fire; and how far the public health and the poorer classes of the people of this realm, and the salubrity and safety of their dwellings may be promoted by the amendment of such laws, regulations, and usages." Here we have, then, a most adequate and plain proposition devising a system of public hygiène for the United Kingdom. "The land (says the *British and Foreign Medical Review*, 1844), of mines and machinery; of railways and steam ships; the land of an overflowing industrious, energetic population; the land of unceasing action; the sun and centre of modern civilization; the beacon set up as a guide to all nations," now at length fairly sets to work to devise some comprehensive measure on a vitally important question, and to propose some remedy for a wide-spreading and growing evil. I find there were above sixty witnesses called before this commission; and the main witnesses on the general subject are practical men; and the local reports of different towns are also introduced, and which have been principally made by physicians and surgeons, and various clergymen—viz., Dr. Duncan, for Liverpool; Dr. Laycock, for York. The names of Drs. Arnott, Clark, S. Smith, Liddle, Guy, Aldis, Rigby, and Mr. Toynbee appear amongst the host of witnesses. The evidence of Dr. Thomas Clark, of Aberdeen, and Mr. Hawkesley, of Rotherhithe, on the quality and impurities of water is most extensive, instructive, and telling. Dr. Clark distinguishes the whole saline contents of water as the neutral and the alkaline; the latter consists of bicarbonates—those of lime and magnesia, and of potash and soda; the former of neutral salts—of earth and alkalies; the earthy salts are, of course, the cause of hardness, which is a condition not desirable for domestic purposes. Dr. C. estimates the annual value of soap consumed per head in London at 6s. 8d. The total value, including the alkaline base, is £630,000; so that the difference of cost between the supply of hard and soft water may be estimated for London, at £200,000.

Dr. Clark also states regarding the presence of organic matters, that such are not separable by filtration. Animalculæ are found to abound in the water of all the London companies; the impurity of London water, doubtless is indirectly a great cause of drunkenness. At the present time there is a comprehensive and apparently

* The gaol is a fine large building, in a most commanding situation, and its magnitude is such that the Government send a great number of felons for confinement in it. It is, undoubtedly, a well-conducted, well-arranged, and model building *of its kind*.—I.

† A Public Improvement Society is just established in Leeds, which may do great good, and stimulate public opinion in these matters.—I.

feasible plan for the supply of London with pure water; thanks to the labours of such men as we are now alluding to. As regards the supply of water to towns, it is now found to be quite practical to supply every house with an abundance of water at a small cost. The price of water in Leeds, as well as that of gas, is by no means cheap; and our water-works will have to be enlarged and the supply rendered adequate for the wants of the town, instead of being stinted as at present.* The vitiation of the atmosphere is one of the most important subjects of inquiry in the report; the effects of deficient ventilation, and the general mortality caused thereby occupy a prominent part, as well as the influence of occupation on the health with reference to ventilation. Dr. Duncan's report on Liverpool is particularly valuable. Dr. Guy personally inspected the work-shops of London, and furnished the Commissioners with much valuable information; one of his conclusions is both important and sad, for the proportion of consumption in the three classes of gentlemen, tradesmen and artisans, being respectively about 16, 28, and 30 in the hundred; and this he attributes to confinement for so many hours in ill-ventilated shops. That scrofulous diseases result from epidemic visitations, is equally strikingly shown by Mr. Toynbee. The modes of improving ventilation pointed out the injurious effects of an atmosphere rendered impure by miasmata, its effects on the morals, &c. The use of opiates, drunkenness, infanticide, mortality amonst infants, are all dwelt upon. It appears that in Ashton-under-Lyne opiate mixtures for infants, sold only by fifteen vendors in that town, amounted to the enormous quantity of nearly seven gallons weekly. The over-crowding and filth of common lodging-houses is brought before the notice of the commission, and sanitary regulations with regard to them are recommended. These remarks will show you what an important field of inquiry was entered upon by this valuable report of the Commissioners. About the time this report was published, some useful publications on the sanitary condition of Glasgow and Edinburgh appeared; in relation to the former, one by Dr. Perry, and to the latter, a treatise by that zealous philanthropist and able professional physician, Dr. Wm. Pultney Alison; all who have the pleasure of knowing him can speak of his sterling worth and earnest ability, and his unwearied exertions on behalf of the poor of the city of Edinburgh. "The Contributions to Vital Statistics as a Development of the Rate of Mortality, and the Causes of Sickness, from original and extensive data, procured from Friendly Societies, showing the instability of Friendly Societies, Odd Fellows, &c., with an Inquiry into the Influence of Locality on Health," by Mr. Neison, and communicated to the statistical society, deserve mention as valuable contributions connected directly and indirectly with our subject. Also the work of Mr. Hollis, on the Social and Sanitary Condition of the Working Classes in the City of Dublin". The journal of the Statistical Society also contains much valuable matter connected with public hygiène and vital statistics.

In 1845 the second Report of the Commissioners appeared—a still more important and valuable contribution to public hygiène than the first, and the one that was the immediate cause of the passing of the Health of Towns' Bill or Public Health Act, and the Diseases Prevention Act, and the appointment of the General Board of Health. The Commissioners state in the second Report, that their investigations and reports have excited increased attention to the importance of providing for the physical condition of the poorer inhabitants of large towns, and that the wealthy and intelligent classes resident in them are now, for the most part, becoming alive to this question, and to the necessity of providing for the removal of those causes which tend to vitiate the air, and increase the mortality of the poor in densely-crowded districts. By this active collection and diligent diffusion of information in matters relating to the public health, the reports of the Health of Towns' Commissioners have done the greatest service to the public, and these good results are now beginning to be experienced, as the recent reports of the Registrar-General satisfactorily show. Such laborious results, though not like popular, exciting, political, or theological questions, are in themselves, as stated at the onset, more permanent in their effects, and really more deserving of the title—patriotic. The Commissioners conclude their report with an outline of the measures they propose and recommend, which recommendations formed the groundwork of the Health of Towns' Bill, now in force, and of the contents of which it is unnecessary to give an abstract, as you can refer to it yourselves. We now, then, arrive at the time when drainage, paving, cleansing, and lighting of streets are recommended, as well as the supply of water, to be placed under an administrative body; when additional powers are recommended to be given in this respect both to local authorities and the Government; when the sanitary regulations relative to the construction and ventilation of buildings and the width of streets should be adopted; and when our common lodging-houses are to be placed under public inspection and controul, and all nuisances put down.

The desirability of these recommendations and measures admits of no dispute; and, as a town, we may congratulate ourselves on having, or at least having had, the opportunity, to a certain extent, of carrying them out (I admit very inefficiently) ever since the passing of the Leeds Improvement Act, in 1842. The question, then, arises, which it would be foreign, perhaps, to this place to discuss, which is the best mode of carrying them into effect?—whether a local board can act more efficiently than a central one? As a general rule we must admit that such matters ought to be under the controul of those who have to bear the expense of them; but in those places and towns where the authorities and public neglect their duty, a central board or governing body surely may safely be allowed to interfere.

* The Corporation of Leeds propose to buy the shares of the Leeds Water Works Company, and go to Parliament for a fresh Act, in order to supply the town efficiently with water, the present Company not being able to do so. An able report on the water supply of Leeds has just been issued from the Town Clerk's office, with an excellent speech on the question by Mr. Alderman Shaw.

I have now brought my sketch of the progress of public hygiène down to the present time; and if we may judge from the valuable reports that are constantly in the course of being made to the General Board of Health, as appointed to carry out the Public Health Act and the Epidemic Diseases Prevention Act, we may fairly assume that public hygiène is making rapid progress; and that as rapidly as its ardent supporters could desire, and as prudence would dictate; for in carrying out new measures concerning the interests of large masses of the people, we must proceed on sound and well-established data, and in accordance with the result of practical as well as scientific research, or we shall retard the measures we are anxious to accomplish, and impede the grand, and till recently little studied, question of sanitary reform. In justice to the writers of the valuable reports we have just alluded to, it would have been an omission not to have named and called your attention to them; and those who wish for really instructive and, I may add, interesting information on such matters will do well to refer to them. The breaking out of the cholera in 1848 (72,000 deaths) of course gave a great impetus to this question, and some of the most recent sanitary reports are principally upon epidemic cholera,—its history, causes, progress, prevention, &c. The reports of Mr. Grainger and Dr. Sutherland are most valuable, full of useful matter, and deeply interesting. And without entering into any discussion as to the origin and prevention of the cholera—a subject which many are inclined (in my opinion erroneously) to think that we know as little about as ever, for I may venture to assert that the result of the most searching inquiries, reports, and investigations of so many able observers, is to show, now, that we are in a position easily to collect facts and draw conclusions, that it is in the power of man, and Providence has placed at his disposal obvious and adequate means for materially lessening, if not altogether preventing, this fearful scourge. Facts innumerable prove that overcrowding, want of pure air, offensive effluvia and exhalations, drunkenness, impure water, unwholesome or insufficient food, intemperance, and fatigue are the determining causes of the invasion and spread of cholera. The recent reports show and prove this beyond all doubt; and equally decidedly prove that sanitary ameliorations have invariably been found active in the mitigation and diminution of choleraic disease. The thinning of a crowded population, the suppression of nuisances, the removal of refuse, the lime-washing of dwellings, the supply of good water, which was scanty or unwholesome, have invariably been followed, and often very promptly, by a diminution and even cessation of sickness. I could name a number of towns where this has taken place; for, as has been truly said, in a recent number of the *British and Foreign Medico-Chirurgical Review* for June, 1851, "Never was there a disease in which the finger of Providence has been more conspicuous than in epidemic cholera. Its whole career manifests that it is a divine judgment, not indeed an infliction of wrath, but a chastisement of rebuke. We have been long neglecting our duties to the poor, and to those that cannot help themselves. Thousands upon thousands are annually swept away by diseases which are more or less under control, or even prevention. What did Dr. Rush say between sixty and seventy years ago? His words are pregnant with meaning:—'To all natural evil, the Author of Nature has kindly prepared an antidote. Pestilential fevers furnish no exception to this remark. The means of preventing them are as much under the power of human reason and industry as the means of preventing the evils of lightning and common fire.' And has not experience confirmed the accuracy of his statement? But have we acted in accordance with the duty which the knowledge of its truth imposes? Or have we not rather, in spite of conviction, allowed the most monstrous physical evils to spring up in our towns and villages—evils that inevitably produce disease, wretchedness, and death? A new and fearful messenger has been sent into our land to alarm and warn us. Hitherto the judgment has been tempered with mercy; we have had but a simple duty to do, and but a few simple rules to obey, and the invasion of the pestilence has been comparatively innocuous. It only requires the will of Him who sent it to intensify its virulence by some degree, and its poisoned breath may spread destruction even in the purest and healthiest localities. Who can say that the third visitation may not come armed with treble power? Does not the history of the ways of Providence in past ages lead the thoughtful inquirer to believe that such will be the case, if duties are left undone and privileges remain unimproved. All classes of the community are deeply interested in the inquiry. How much should it then engage not only the serious attention, but also the active and serious labours of the members of that noble profession the great end and object of whose mission is to save life, mitigate suffering, and ameliorate the condition of their fellow-man."

Besides the reports and investigations of Mr. Grainger and Dr. Sutherland, the labours of our metropolitan and provincial brethren,* when the epidemic existed so generally, all parties must admit were beyond all praise, so that it would seem invidious further to give names; but I only make the exception when they refer to writers of official and special reports. Under this head I must name Drs. Burke, Milroy, Lewis, Hector Gavin (the latter, I believe, recently sent by Government to Jamaica, to treat the disease,) Mr. Simon, the Officer of Health for the city of London, (who has been facetiously termed by *Punch*, the real "Simon Pure,") and others, whose reports are most useful and suggestive.

The names and labours of Lords Carlisle and Ashley, (names ever found in connexion with what is ennobling,

* A number of local reports, treatises and essays on cholera—its origin, statistics, termination, and treatment, &c., in different localities, have appeared from time to time from the pens of medical men. One by Dr. John Taylor, of Huddersfield, most satisfactorily discusses this subject, and his views agree with those of Dr. Sutherland and Mr. Grainger. Dr. Budd has written "On its Propagation and Prevention;" Mr. Brittan "On its Pathology," &c., and many others.

useful and philanthropic,) Dr. Southwood Smith, and Mr. Chadwick, are both known and appreciated, and they form the General Board of Health, from whose reports and suggestions we have a right to expect great things; still we must admit, these, in themselves, are comparatively worthless unless the public are influenced by them, take them up, and carry them into practice; hence one of the great objects of a paper like this should be to call attention to these reports and recommendations. Before alluding to the most recent publications of the General Board of Health, I may state, that in 1847 a valuable document appeared in the Report of the Metropolitan Sanitary Commission, written by Sir William Clay, and entitled, "Remarks on the Water Supply of the Metropolis, and was both opportune and useful; as well as that of Dr. Robert Angus Smith, entitled "Report on the Air and Water of Towns." The recent Report of the General Board of Health on "Quarantine," as well as their letter to the Lords of the Privy Council, "On the Practice of Quarantine in England," deserve an attentive study, and as fairly and ably discuss the question as a comparatively non-medical board can be expected to do, but the complicated and delicate questions of contagious and non-contagious disease, and the utility of quarantine, are still questions to all impartial minds and careful observers, *sub judice*. (A congress of Savans is now sitting in Paris, to report upon the supposed contagious and infectious disorders, and on the practice of quarantine, &c.)

The reports of Dr. Sutherland and Mr. Grainger "On Cholera," are models of what such documents should be; and why the labours of such men, along with many others of the medical profession, are not as deserving of the rewards and honours of the State, as those of mere political partizans and agitators, or caterers for public amusement is, I think, difficult to explain. But surely we are on the eve of better times, and due regard will henceforward, as respects State patronage and emolument, be paid to the just claims and arduous duties of the medical profession. The lawyers are sure of many prizes, and those the highest the State can award, and have an especial dislike to see the finger of reform pointed to their profession and their musty, multitudinous, and confusing documents and acts; all the snug berths created by our laws, are mostly in the hands of the lawyers. And the divines, (I say it with all respect,) have a peculiar attachment and eye to a good living, and to the distinctions, titles, and rank, to be found connected with the government of the Church; and the heads of it certainly cannot, with propriety, apply to themselves the striking words of the highest authority—"Silver and gold I have none," whilst the members of our profession, with few and rare exceptions, can never look forward to either State patronage or emolument, to honorary titles or distinction, still we are mulcted to the support of that State in the same proportion as if our incomes were as safe and certain. But I am digressing. Besides the reports referred to, I have to name in particular, the two recent ones, (1850,) that of Dr. Sutherland, "On a General Scheme of Extramural Sepulture," and that "On the Supply of Water to the Metropolis." Both these important publications will do much towards an extension of public hygiène. Both these documents will amply repay an attentive perusal, and the reader will not fail to become, not only instructed, but really interested in these important inquiries. A review of the "Report on Extramural Sepulture," has recently appeared in the *British and Foreign Medico-Chirurgical Review*, which contains some really beautiful writing. A few of the sentences referring to this subject I here introduce, as they struck me forcibly at the time of reading them, and I am sure they are well worth repeating. The reviewer writes:—"A fastidious and sensitive mind might perhaps find something to wound its susceptibility in the mode of conducting the funeral rites of most nations. It might not find any solemnity sufficiently awful—any ceremonial adequately expressive to fulfil its conception, as to how the last duties should be paid to the earth about to return to its kindred elements. It might find something repugnant in the sudden dispersion of the atoms of the frame so lately gifted with vital motion, by the flames of the funeral pile; it might equally object to the mockery of preserving these inanimate atoms as if the art of the embalmer could obliterate the ineffaceable seat of the King of Terrors. But if a curious inquirer should deem it worth his while to glance over the funeral rites of ancient or modern times, he would find that, however, in some points, they may fall short of his conception, such ceremonials have always been conceived in a spirit of grand and solemn poetry. The Greek, crowned with flowers and stretched on his last couch, formed with fragrant and precious woods, as if the flames which were to consume him should spring from no common source;—the Brahmin carried solemnly to the banks of his sacred stream, and then gently committed to the purifying waves;—the Scotch Highlander, buried at night, by the light of the torches of his Clan;—the Red Indian covered with his trophies;—the savage, laid in his solitary forest grave, amid the melancholy sound of the wailing death-song of his tribe, present so many examples of the same spirit of remorse, grief, and humility, which led the early Christian Church to throw around the burial of the dead, that most impressive ceremonial, on which are so marvellously blended—sorrow, pity, and hope for the departed, and warning and admonition for those whose turn must shortly come. Even those nations which we in these days of boasted progress, are accustomed to regard as little better than barbarians (just emerging from the shade of their primitive forests), exhibit for the most part, in their present solemnities, a spirit of which Christian communities could not be ashamed. The shortness of life, the frailty of mortality, the dread mystery of that strange secret, which all men must sometime know, impress the Caffre or the Dyak no less forcibly than the Briton or the German.

The customs of our own country, if they cannot vie in grandeur and impressiveness with the stately ceremonial of the Assyrian and the Greek, are yet

impressive and solemn, and have a more lasting, if not so immediately thrilling, an effect. In order to encourage these devotional feelings still more, the Church, in the eighth century, commenced the practice of allowing the dead to be buried in the vicinity of the churches, so that at once the body might be laid in undisturbed and consecrated ground, and the survivors might associate that holy spot with the place in which they assembled to discharge the rites of religion. In this way, also, as the churches stood generally at some little distance from the mass of dwellings, the resting place of the dead was not disturbed by the harsh and discordant murmurs of the exciting bustle of those who had succeeded at the feverish strife and turmoil of existence. When, indeed, one of the active agents in life's May game turned his footsteps for one moment into the still inclosure, shaded by its funeral boughs, he could not fail to be recalled, by the quiet sanctity of the place, to a recollection of the doom which awaited him, and of the mode of life which ought to be a preparation for that fate.* So also the bodies of the dead were then allowed to resolve themselvs into their original atoms without the living suffering from the inevitable emanations, for as every inch of ground was not, in these days, worth its weight in gold, the cypress and the yew were permitted to plunge their purifying roots into the ground, and to transmute into their own beautiful forms those particles which had ceased to constitute the fleshly temples of immortal souls. Nor were these rites, this ceremonial, these influences in the minds of the survivors, intended for one single class of the community. The Christian Church, knowing no differences of rank on the day when the common lot has rendered such differences impossible, whether poor or rich, there was devised the same farewell for the dead, the same solemn admonition for the living. The rich man might, indeed, sleep in his vault, and the 'rude forefathers of the hamlet,' in their graves of turf, but the same influence sanctified both, and the simple cross over the mound of earth was as sacred as the marble sepulchre, or the heraldic pomp engraved on brass. Knowing, then, the intention of the Church, and consulting the feelings of our nature, by keeping uncontaminated and undisturbed the relics of mortality, how needful was it for the State to interfere in order to prevent the unholy and almost inhuman mode in which interments too often take place in the midst of London and many of our other large cities. If you read the report on Extramural Sepulture and Evidence on Interment in Towns before Parliament, and the praiseworthy reports of Mr. Walker on this subject, the mind feels horror, astonishment, and disgust at the mode in which, in the nineteenth century, and in the centre of the civilized world, funeral obsequies are conducted in the English metropolis, in which 52,000 bodies have annually to be disposed of. During the last 150 years, and particularly in the last half century, London has been literally rising like magic out of the earth. On all sides the suburbs and the open country around have been invaded by its new streets. Churches built even lately, and the name of which often signifies that they stood in fields, now stand almost in the heart of the city; the dwelling-houses are carried up to the churchyard walls. (and this is not confined to London, but is the case in most of our large old cities and towns,) and the habitations of the living, and the abodes of the dead, are in the closest proximity. Thence it comes that the silence of the graveyard is violated by the hum of common life, and the stillness of the tomb is a phrase which has no meaning. The old solemnity of the burial place becomes destroyed, and the steps of men, absorbed in the cares of trade and speculation, cross, without a moment's reflection, the repositories of their departed friends and relatives. The exact state of matters in London has now been so completely laid open and exposed, that common prudence and decency forbid the continuance of intramural interment, and the Board of Health have (thanks to Mr. Walker and others) now proposed to deal boldly with the question, and have brought forward an efficient mode of remedying such a fearful evil; it is, "that every existing graveyard in London is to be closed, no more bodies are to be thrown (for it is nothing more) into them; burial grounds are to be made outside the city, apart from the busy tread of men and the hum of commerce, and these burial places are to be rendered easily accessible even to the poorest. The pauper will be then carried there as solemnly as the peer, and buried with equal decorum; the exhalations of the ground will no longer exert a poisonous influence, and the burial grounds themselves will present the appropriate character of the mausoleum of a great city."

To fulfil these conditions the Board proposes to form a vast cemetery at Erith-on-the-Thames, several miles below London, and to enlarge Kensal Green and the other cemeteries. The advantage of having the principal cemetery at Erith, is its easy access by water, its distance from London, and the existence of a suitable piece of ground. The Board proposes, also, to have receiving houses at convenient distances on the banks of the Thames, to which the relatives may convey the body, afterwards to be placed on board a steamer for conveyance to Erith.

If these measures are carried into effect, along with an adequate supply of pure water to London, "the Board will have accomplished the first of a series of social changes, which will be without parallel in the beneficial effect they will produce in the dense masses of the labouring classes."

If, then, it is found practicable in London, with its population of above two millions, to dispense with intramural interment, and to provide an adequate

* A.D. 740 Cuthred, brother to King Etherard, succeeded him in his Dominions, and was much disquieted by Edilbald, King of Mercia, both by open war and privie practises; but these two Kings coming to a conclusion of peace, joyned both their powers against the over-borne Britaines, and in a bloody battle gave them a great overthrow. In this time saith Beda, the bodies of the dead were permitted to be buryed within the walles of their cities, which thing before was not lawfull, but their corps were interred without in the fields; many of whose tombs are as yet witnesses to us, that daily find them in digging of the grounds adjoyning and reserve them for sight or other necessary use.—*Speed's History of Great Britaine.* Third Edition. 1632. p. 229. (This note was sent me by a medical student.—I.)

supply of water at all hours, for the use of the inhabitants, surely there is no excuse for any town in England remaining behind London in the promotion of such necessary sanitary measures. With regard to a supply of water, we may add, in the words of the *Times*, "that it is now a plain and fundamental maxim of sanitary economy, social policy, and good government that the water we use should be no more an article of trade or taxation than the air we breathe or the light we enjoy." Thanks to the exertions of the sanitary reformers we are now promised light—that boon of Heaven—without paying a tax for the use of it.

[To be continued.]

ON THE

INEFFICACY OF KOUSSO IN SOME CASES OF TÆNIA.

By EDWARDS CRISP, M.D., London.

Read at the Nineteenth Anniversary Meeting, held at Brighton, August, 1851.

Case 1.—On February 20th, 1851, at the Metropolitan Dispensary, I gave this medicine to a boy, aged 6, who I thought had been cured by turpentine some months before. He took in my presence, at different times, three doses, two of two drachms, and one of a drachm and a half, but no portion of the worm was expelled. He now passes joints of the worm frequently.

Case 2.—February 28, 1851.—A girl, aged 12, took two doses of three drachms each, and nine feet of the worm were expelled. She has up to the present time had no return of the complaint. This patient I had also administered turpentine to, and I supposed she was cured by it. The second dose of the medicine produced a great deal of griping pain.

Case 3.—Mrs. T., aged 59, came to the dispensary May 20th, 1851. She has been affected with tapeworm for eight years. Three years ago she had a convulsive fit, and lost the use of her side for three weeks. Has taken no anthelmintic. I gave three drachms of kousso, and in six hours thirty feet of the worm came away; and at present she appears to be cured. This patient had also deafness, palpitation of the heart, and partial loss of sight.

Case 4.—W. R., aged 59, applied at the dispensary May 16th, 1851. Has had tænia for three years. Twelve months since took turpentine; but it produced tenesmus and great pain on micturition. I ordered him half an ounce of kousso, and thirty-three feet of the worm passed after five or six hours. But in this and the other cases the *head was not found*. This man came to the dispensary a fortnight since, and brought several joints of the worm, that had escaped per anum. I have ordered him two doses of the oil of turpentine, but I do not yet know the result.

During the last two years, at the Metropolitan Dispensary, I have prescribed for thirteen cases of tænia, Ten of these patients took turpentine, and seven appeared to be cured. In one no beneficial effect was produced by it; and in two, the worm, although apparently removed after the turpentine, was not all expelled. The latter patients (cases 1 and 2) afterwards took the the kousso. One patient was pregnant, and therefore anthelmintics were not prescribed.

I conclude, from the above evidence, that kousso does not always remove the head of the worm; and that it cannot be considered a specific for tænia; that its action is milder than that of turpentine, and the greater part of the parasite is generally removed *en masse* by it; but it is questionable whether its efficacy in tænia is much superior to that of turpentine, which, when first employed, was also lauded as a specific.

THE LEFT ARM AND HAND OF A CHILD FOUND IN A STATE OF PUTRESCENCE, FROM STRANGULATION, THE FUNIS BEING TIGHTLY BOUND ROUND IT AT THE UPPER PART.

By ALBERT OWEN, Esq., Aylesbury.

On the 3rd of June last I was sent for to a woman, the mother of four children, who was miscarrying in the seventh month of her fifth pregnancy. I found the membranes ruptured, a large discharge of the liquor amnii to have taken place, and the labour pains occurring every fifteen or twenty minutes. There was not any flooding, neither could I, by examination, feel the child. She continued in this condition for another six hours, when the pains ceased, and she went on with her pregnancy to the full period of gestation, without any other inconvenience besides what she termed a constant "dribbling of the waters." On the 27th of July, two months after, I was again hastily summoned, and found the pains strong and regular, the os well dilated, but no portion of the child to be arrived at by manual examination. I, therefore, gave her a dose of the pulverized secale cornutum, which had the effect of increasing the strength of the pains; and in less than half an hour I discovered a hand outside of the vagina, and the head tightly wedged against the brim of the pelvis. All attempts to return the hand, or to pass my own, so as to turn the child, were perfectly useless; and I, therefore, resolved to leave the management of the case for the next half hour to nature, when, much to my satisfaction, as if under some violent and sudden impulse, the uterus discharged the whole of its contents with such force that the fœtus and placenta both came away *en masse*. The child was dead, apparently not many hours, but the entire of the left upper extremity was in a shrivelled, livid, and putrid condition, the funis tightly bound round and imbedded in the upper part of it, just below the insertion of the deltoid; in fact, the limb did not appear much more than half the size of its fellow on the other side. The mother had a good getting up, and seemed none the worse two days afterwards.

Provincial Medical & Surgical Journal.

WEDNESDAY, OCTOBER 15, 1851.

THERE is in the present aspect of medical affairs enough to make any one, who is not thoroughly imbued with confidence that truth and honesty must ever in the end be triumphant, believe that true medical science is destined to be extinguished. Not only is it overlaid by every species of foolery at which a gullible public can be made to gape, but there seems to be a determination even on the part of those who ought to be its supporters, to cover it with contempt and obloquy. Take, for instance, the conduct of those sapient dispensers of public charity—the Poor-Law Guardians. What do we see but the melancholy spectacle of an educated man, and oftentimes a man of refined feelings, subjected to the galling insults of bucolical ignorance. In the Navy, too, the surgeon—the equal in fortitude and chivalrous daring of any officer in the ship, the superior of all in most mental accomplishments, and frequently no mean proficient in nautical science; such a man we see treated as of less consequence than the captain's steward, or at least we did see this, until the Lords of the Admiralty, spurred into a sense of justice by the indignant voice of the profession, have tardily seen to the abolishment of so disgraceful an anomaly. But in the Army some will say—there, at least, the medical officer is subjected to no indignity, nothing occurs there which can grate upon the feelings of a gentleman. Is it so in reality? Let the experience of any army surgeon speak to it. If it has not been so in every instance, the cause is to be sought in the character and qualities of the individual, not in a respect for his position as a member of an enlightened profession. But how can it be otherwise, when everything that can lower him in the eyes of his comrades, as well as of the public at large, is sanctioned by the authorities? Lest we might be thought to exaggerate the indifference which the medical officer meets with at the hands of Government, we transcribe the following circular which has recently been issued from the Horse Guards:—

"*Military Deserters,*"

"Horse Guards, August 19.

"In consequence of the diversity of the practice and insufficiency of the existing methods of marking the deserter with the letter D., and it being found in many instances that the mark has been obliterated in a short time, and even been removed by artificial means, it has been decided that from the first of October, next, this part of the sentence of the Court Martial shall be inflicted, in all cases where practicable, in the military prisons, by the medical officer [!!] attached to each of these establishments, and under special instructions from the Secretary at War.

"G. BROWNE, Adjutant-General."

This disgusting order is indeed the climax of Government insults, and must have the effect of opening the eyes of the blindest medical officer to the position in which he is regarded. It is manifestly impossible that any medical *gentleman* can remain army surgeon after the above date; for although the honourable office of deputy-executioner will only devolve upon the prison surgeon, the stigma will cling equally to every medical officer in the service. A wholesale resignation, unless the disgraceful order be rescinded, is the only method of bringing the Horse Guards to their senses, and we earnestly trust, for the honour of the profession at large, that our brethren in the army will have the spirit in this manner to vindicate their claims to be considered something better than a mere hangman's assistant. If they do not cause this humiliating order to be rescinded, whatever may be thought of him at his own mess-table, the army surgeon may feel assured that in civil life, he will be placed in the same rank as the regimental farrier, and will be allowed to subside for his acquaintances, to a corresponding grade in society.

Since writing the above, the offensive order has been deferred until further notice.

THE manifesto of our Association has fallen like a bomb-shell among the homœopathic quacks; and many of them, we have reason to know, are already turning it over in their minds, whether it will not be more advantageous to them *in the end* to give up their globules and return again to the honourable and more rational practice, which an inordinate covetousness, or a puerile credulity had led them to abandon. Some, too, whose lax consciences have allowed them to consort with these practitioners for *diagnosis sake*, are beginning to feel in their consultation practice, that it is safer to trust for eminence to the support of the profession, than to hang on to the skirts of globulistic professors. All in good time; another year or two will convince most of these parties that their true interest is inseparable from strict professionial probity. The out-and-

out Hahnemannites, however, are not to be frightened, but have published a counter manifesto, which we here reproduce :—

"1. That homœopathy is thoroughly reconcileable with science and common sense, [!!] is in accordance with the experience of some thousands of medical men, and deserves the study of practitioners and the confidence of the public.

"2. That the framers of the hostile resolutions referred to, and other prejudiced opponents are totally ignorant of homœopathy, avowedly refusing to study its principles (in the writings of Hanhemann and others,) and to witness its practice in the homœopathic hospitals and dispensaries, to which they have been repeatedly and cordially invited.

"3. That notwithstanding the difference in their treatment of disease, there can be nothing derogatory in homœopathists and allopathists (equals in education, science, and social position) consulting together at the request of patients and their friends as to the nature of the malady.

"4. That the resolutions of the Provincial Medical and Surgical Association, representing as they do, the opinions of only a small fraction of the allopathic body, are in themselves, and for the reasons given above, utterly valueless.

Wm. Macdonald, M.D., F.R.C.P.E.,
Professor of Civil and Natural History in the University of St. Andrew's.
James Chapman, M.A., Cantab., M.D.
Edward Hamilton, M.D., F.L.S.
David Wilson, L.R.C.S.E.
Thomas Seadam, M.R.C.S.
Robert E. Dudgeon, M.D., Secretary."

We notice a communication in a late number of the *Lancet* without hesitation, as we fully believe that it is an impudent invention of the homœopathic press, and one which the distinguished physicians alluded to will repudiate with honest indignation. Speaking of two prescriptions by these gentlemen, in which belladonna was given for scarlatina, the Editor of the quack journal appends the following comments :—

"Most of our readers are fully aware of the fact that the practitioners of the allopathic school ever and anon resort to remedies given on the homœopathic principle,—*aconite*, *arnica*, and *belladonna*, have been again and again given in this way by many allopathists. *The two eminent physicians mentioned by our correspondent, have distinguished themselves by their gentlemanly forbearance, and their courteous demeanour towards their homœopathic brethren. Neither of them has ever made any difficulty of meeting in consultation, at the request of the patient, any homœopathic practitioner, not for the treatment but for the opinion of disease.* Other eminent men of the 'Faculty' have no less stood aloof from the intolerant bigotry and insolent exclusivism of a certain class of allopathists."

It is but justice to Sir James Clark and Dr. Locock, the gentlemen in question, to state, that their prescriptions were anything but homœopathic as regards dose, a quarter or a fifth of a grain of belladonna being given three times a day. To say that a physician is not to prescribe belladonna in scarlatina because the homœopaths choose to rest its value upon their absurd theory, is too ridiculous; as well might we be forbidden to give quinine in intermittent fever. As to these gentlemen being entitled to the praise which is affectedly bestowed upon them, for meeting the homœopaths for "diagnosis" sake, we do not believe a word of it. Still we respectfully urge upon both Sir James Clark and Dr. Locock, for their own sakes, to deny the imputation upon their character. Rumours, it may be added, are also rife, that a distinguished surgeon does not think it beneath him to attend, chirurgically, to a gouty nobleman's toe, while a homœopathic doctor takes the charge of his stomach. These backslidings do not escape the notice of the profession, which will assuredly make its opinion of such conduct known in a manner not to be mistaken.

Reviews.

Practical Treatise on the Diseases of the Heart and Lungs, including the Principles of Physical Diagnosis. By W. H. Walshe, M.D., &c. London: Taylor and Walton. 1851.

Dr. Walshe's present publication consists of two parts, one devoted to the description of the principles of physical examination of the heart and lungs, the other to the consideration of the diseases incidental to those organs, in the various phases in which they become interesting to the clinical observer. To those who are acquainted with Dr. Walshe's great proficiency in all matters connected with physical examination of thoracic disease, as well as with the unsurpassed field for observation which is at his command in his capacity as Physician to the University College and Brompton Hospitals, it is needless to state that he has here presented the reader with a perfect history of the science and practice of auscultation, as far as it has at present advanced. The only fault that it is possible to find, is that of, as it appears to us, unnecessary minuteness of detail, which is calculated to appal, rather

than to enlighten the student, already sufficiently overwhelmed with the amount of information to be crammed or *ground* into him in the two or three years, which by a pleasant fiction are supposed to qualify him to hold in his hand, humanly speaking, the issues of life and death. This, however, is not so much the fault of the writer, as of the age, an age distinguished by a tendency to dwell upon insignificancies and non-essentials.

When the entire subject, with the exception of the fault alluded to, is so well managed, it is difficult to make selections with reference to pre-eminence, either in accuracy of diction or practical value, but as a specimen of the author's mode of treating this division of his labours, we transcribe the following account of the theory of bronchial respiration:—

"The theory of bronchial and blowing respiration commonly admitted, is, that the murmurs produced by the air moving in the larger bronchi, or (as the lung-movement is excessively diminished, and therefore little air—it may be none—can reach even the medium-sized tubes) the air, moving in the trachea, larynx, and main bronchi of the non-affected organ, is transmitted thence through the hepatized or compressed tissues, with an intensity directly as the conducting power of the lung is increased by consolidation. Three objections occur to me as negativing this explanation:—Pneumonic murmurs habitually differ in quality and pitch from those of the larynx and trachea; they are habitually much stronger than the latter, while in some cases of perfect consolidation, (without obstructed bronchus,) there is dead silence over the hepatized structure. Skoda holds that the laryngo-tracheal murmurs, and those of both main bronchi, consonate in the air contained in the bronchi, permeating the solid parenchyma, and thus produce the phenomenon of bronchial respiration when intense, and of high pitch; whereas weak bronchial respiration of low pitch comes directly without consonance from the lower part of the trachea, the main bronchus, or one of the second order. This essential distinction of the sources of weak and strong bronchial respiration seems artificial, and is not supported by clinical facts; besides, the pitch of metallic pneumonic respiration is irregularly higher than that of the laryngo-tracheal sounds, whereas consonating sounds are always either of the same pitch, or of pitches bearing a certain definite relation to each other."—p. 94.

The mechanism of the *crepitant* rhonchus is still, according to Dr. Walshe, an unsettled question, but he is so far decided as to be satisfied that it is not produced in the interior of the vesicles. The most probable explanation he believes to be, that it is produced in the parenchyma of the lung itself, and that its physical cause is the sudden and forcible expansion of that parenchyma glued together by viscid exudation.

The second portion of this work, although it contains little that is not to be found in other treatises on the pathology of the thoracic organs, must be acknowledged to present to the junior practitioner as valuable a practical guide as any extant. This portion of the work has, moreover, the merit of conciseness. The first subjects mentioned are neuralgia of the lungs, pleurodynia, and intercostal neuralgia. The author then proceeds, *seriatim*, with the ordinary diseases of the lungs, including bronchitis, (acute, chronic, plastic, and syphilitic); acute and chronic pleurisy; pneumonia; gangrene of the lungs; phthisis; asthma, &c. From these pages we shall make a few practical selections.

The treatment of *pneumonia* in Dr. Walshe's hands is active, when the disease is primary and acute. In such cases, bloodletting, within due limits, appears his sheet-anchor, next to which he places most confidence in tartar emetic. Mercury is not held by him in much esteem, he considers it only desirable when antimony is inadmissible. A hint is thrown out that the free administration of alkalies might be useful, by meeting the indications afforded by the large amount of fibrin in the blood.

In secondary and latent pneumonia the treatment is different. General bleeding is rarely admissible, and a judiciously sustaining regimen is advised in preference to the antiphlogistic. In estimating the particular value of any line of treatment in pneumonia, the author points out the importance of a reference to statistics of age in connection with mortality. In the very early and late periods of life, he remarks, that it is difficult to save a patient labouring under sthenic pneumonia; in middle life, with judicious treatment, it is as difficult to lose him.

The chapter on phthisis is, upon the whole, one of the most instructive in the book, containing as it does more particularly, the results of the author's original observations while Physician to the Brompton Hospital. On the subject of diagnosis his remarks are eminently practical, as may be seen in the following quotation:—

"A young adult who has obstinate cough, which commenced without coryza, and without obvious cause—a cough at first dry, and subsequently attended for a time with watery or

mucilaginous expectoration, and who has wandering pains about the chest, is, in all probability, phthisical. If there be hæmoptysis to the amount of a drachm even, the diagnosis becomes, if the patient be a male, and positively free from aneurism and mitral disease, almost positive. If, in addition, there be slight dulness on percussion at one apex, with jerking or divided respiration, while the resonance at the sternal notch is natural, the diagnosis of the first stage of phthisis is next to absolutely certain. * * If there be cough such as described, and permanent weakness and hoarseness of the voice, the chances are very strong (provided he be not syphilitic) that the patient is phthisical. If decidedly harsh respiration exists at the left apex, or at the right apex behind,—if the rhythm of the act be interrupted, and there be dulness, so slight even as to require the dynamic test for its discovery, there can be little doubt of the existence of phthisis. If, with the same combination of circumstances, deep inspiration evokes a few clicks of dry crackling rhonchus, the diagnosis of phthisis, as far as I have observed, is absolutely certain," &c., &c.—p. 394.

In the treatment of phthisis Dr. Walshe fully confirms the general opinion of the value of cod-liver oil, maintaining that its remedial powers are superior to those of any other agent, but admitting at the same time that the degree in which it is able to *cure* the disease is still undetermined.

The latter portion of the volume is devoted to the diseases of the heart and great vessels, but the limits of this notice prevent our doing more than enumerating the subjects discussed. These are :—Functional palpitation, angina pectoris, pericarditis and endocarditis, organic diseases of the parietes and valves of the heart, cyanosis, rupture, aneurism, and polypoid concretions. The diseases of the aorta are :—Aortic pulsations, arteritis, calcification, and aneurism.

In concluding our notice of this volume we have great satisfaction in according to it a high place as a practically useful book. Should a second edition be called for, as it probably will be, some material advantage would, we think, be derived from a condensation of the first part relating to auscultation. A good deal is now admitted which must be regarded as a matter more of scientific curiosity than clinical value, and the suppression of which will, we are sure, be considered as enhancing the usefulness of the treatise as a guide to the student and young practitioner.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

JULY 3RD, 1851.

T. W. WILLIAMS, ESQ., IN THE CHAIR.

Larynx and Thyroid Cartilage Perforated by Ulceration; the right Lung in an advanced state of Ulcerative Disease, and studded with numerous small Cavities: the left generally affected by Tubercular Deposit. An Old Cicatrix at the top of the Right Lung.—By Dr. FLETCHER.

THE following is an outline of the case :—

Dr. Fletcher was called to attend Joseph Partridge on the 2nd of June, 1851. He had been ill some time, and was much emaciated, and in a very weak state. He was suffering from great constriction of the cavity of the larynx, so as to be threatened with suffocation at any moment; and there was much swelling and redness of the neck in the neighbourhood of the larynx. The voice was a very low and hoarse whisper. On examining the chest it was not remarkably dull upon percussion, and not more so in one part than in another; on auscultation respiration was next to inaudible; the pulse was 120 in the minute, and feeble; tongue white, and coated; great difficulty, and pain upon swallowing; thirst very troublesome; bowels open; urine sufficiently abundant, turbid from lithates, otherwise healthy, specific gravity 1020; his cough was very troublesome, and with great difficulty he spat up thick muco-purulent matter.

He states that he has been thought to be consumptive latterly by his medical attendants. About four years since he consulted Dr. Fletcher; he was then suffering from laryngitis, which from the history was considered to be syphilitic, (as he confessed to having had syphilis in several forms, and had not submitted to any regular treatment,) and was treated by mercurials and iodide of potass, and much improved as to the disease and in his general health; but he did not continue his remedies long; he took a situation as coach-driver, and resumed his habits of drinking and excesses of all kinds, and has within the last twelve months been unable to undertake any occupation. Hirudines iv., regioni laryngis. R. Hydrarg. Chloridi, gr. ss.; Sacch. Albi., gr. ij. M. Ft. Pulv., tertiis horis sumend.—R. Hydrarg. Oxydi, dr. ij. Ft. pulv. pro fumigatione oris.

This treatment was continued, and as the mercurial action became evident in the system, the disease of the larynx became less urgent, the voice became more loud and the breathing more free, the swelling and inflammation of the neck much diminished and subsided altogether, and large quantities of purulent matter were expectorated.

On the fourth he was able to swallow a little medicine, and a tablespoonful of mixture, containing small doses of dilute hydrocyanic acid was recommended to be taken every alternate hour.

On the 12th the half-grain doses of calomel were omitted to be taken every other hour, and the following pill every night given instead, as he complained that his nights were restless, and the mercurial action was sufficiently established: — R. Pulv. Opii, Hydrarg. Chloridi, utrq., gr. j.; Extr. Hyoscyami, gr. ij. M. Fiat Pil. omni nocte sumenda.

On the 16th, he was admitted an in-patient into the General Hospital. He was generally improved. He was directed to continue his remedies, and to take half an ounce of cod-liver oil twice a day.

On the 18th a morphine linctus was directed for the cough. Since the breathing had become better, the physical signs of disease of the lungs became evident; there was pectoriloquy at the upper part of the right side of the chest, and crepitation all over. His strength began to give way, and he rejected beef-tea, wine, arrowroot, and other nourishment which he had latterly taken.

On the 23rd the case was considered perfectly lost; a mixture containing ammonia was ordered and all other remedies stopped.

He died on the 24th.

Post-mortem examination.—Head: Brain healthy. *Chest and neck:* The larynx was considerably ulcerated, the chordæ vocales destroyed, the thyroid cartilage perforated in its middle, and communicated with an abscess in the parietes of the neck anterior to it. The lungs were in the state above described. The heart healthy. Viscera of the abdomen and pelvis healthy.

This case was particularly interesting from its history connecting it so closely with a syphilitic origin, and the obstruction of the passage of air to the lungs by the larynx obliterating so effectually the physical signs of respiration and of the disease of the lungs.

Foreign Department.

Reappearance of the Sweating Sickness.

This terrible malady, which caused such fearful ravages in the middle ages, appears to have visited some parts of France. It is stated in the *Journal de l'Arrondissement De Valognes*, that on a particular Sunday there were seven or eight deaths, and seventy new cases.

New form of Varicose Aneurism.

Two different lesions may follow as a consequence of the simultaneous wound of a contiguous artery and vein. In certain cases the blood passes directly from the artery into the vein; the latter becomes dilated either in the exact locality of the wound, or at some distance between it and the nearest branch. This is *aneurismal varix*.

In other cases a tumour is formed, the size of which is limited by the surrounding cellular tissue, and into which the arterial blood penetrates. The communication of the tumour with the vein gives it some other peculiarities, and it is called *varicose aneurism*.

Writers have generally mentioned the following as the characters of varicose aneurism:—A canal, of greater or less length, runs between the artery and the vein, establishing a communication between the two vessels; at some point there is a sac, bounded by cellular tissue. This lesion, which is more rare than the other, has only been submitted to dissection three or four times, and therefore M. Berard reports the following example (*Memoires de la Societe de Chirurgie*):—

A man, aged 40, who was in the habit of being bled for some cerebral affection, had the artery opened by mistake in 1840; a bandage was placed on the puncture. In the morning after the man complained of a pain in the arm, with the sensation of burning along the course of the vessels. Attributing this to the bandage, he loosened it, when the limb began to swell; the tumefaction reached the shoulder and wrist, the skin becoming at length quite black; soon after pulsation became perceptible in the fold of the elbow and lower part of the arm.

After the tumefaction had subsided, a soft fluctuating tumour was found on the inner side of the tendon of the biceps; its pulsations were distinct and isochronous with those of the arteries. The entry of blood into the tumour was accompanied with a distinct bruit. In addition to this a bruit was propagated along the veins, but of a distinctly different character from that which was heard in the tumour. From these signs the author at once perceived that he had a combined case of varicose aneurism and aneurismal varix. After a variety of treatment he found it necessary to tie the brachial artery.

Compression being made accordingly in the superior two-thirds of the track of the vessel, an incision was made in the bend of the elbow, exposing the anterior portion of the sac; this was likewise opened, giving issue to dark fluid blood, mixed with clots. The upper portion of artery when it entered the sac was then ligatured. It was now found that, although the vessel was tied, blood continued to pour into the sac from below, and the author with great difficulty found the lower opening of the vessel, which was hidden from view by the interposition of the vein; in fact the exact condition of the parts was this:—The artery presented a large transverse wound on its anterior surface; in front of the artery lay the vein, glued to it, and itself pierced beneath by a wound corresponding to that of the artery, and above by another of the same dimensions. Above this was the aneurismal pouch, so that the blood from the artery traversed the vein in reaching it.

The explanation of these lesions given by the author is, that during the venesection the vein was pierced through, and the artery opened; the lower puncture in the vein remained open while the upper cicatrized, and an aneurismal varix ensued. After a time the impulse of the blood upon the upper surface of the vein caused the puncture to reopen, and an aneurismal pouch then formed in the external coat of the vein and cellular tissue.

Treatment of Anæmia in Children by the Extract of Bullock's Blood.

Dr. Mauthner (*Revue Medico-Chirurgicales*) is said to have adopted this mode of treating anæmia for some time. The extract is prepared by straining and evaporating the blood to dryness. The extract is powdered, and given in doses from ten grains to a drachm. The cases in which he has found it especially useful are:— 1. Those in which anæmia has supervened upon protracted diarrhœa. 2. In the anæmia after typhus. 3. In anæmia following profuse suppuration. 4. In the anæmia resulting from albuminuria. He has found it useless in tuberculosis.

Spontaneous Luxation of the Shoulder-Joint.

Spontaneous dislocation of the hip-joint, as a consequence of disease, is a familiar occurrence to surgeons, but it is very rare to meet with a similar lesion in the joint of the shoulder. The following interesting example is recorded by M. Hannon, (*Presse Med. Belge,*) in which the humerus was displaced during the course of an attack of acute arthritis:—

A man, aged 45, of robust constitution, became the subject of rheumatic inflammation of the shoulder-joint. The pain was acute, the tongue furred, skin hot and perspiring, and in fact he had all the symptoms of rheumatic arthritis in its most acute form. The swelling of the shoulder appeared on the second day, and continued to increase until the sixth day, when the patient suddenly felt a sudden tearing pain, which was the induction of the head of the humerus having left its situation. When examined next day the elbow was separated from the trunk, the arm turned outwards, the fore-arm flexed, and held by the other hand; the shoulder was flattened. Passing the fingers under the acromion, a cavity was at once perceived, and the head of the bone was found in the axilla.

The dislocation was reduced, and the bone maintained in its place by proper bandaging, and from this time there was considerable relief to the pain, as well as subsidence of the tumefaction of the joint. A few days after a second partial dislocation occurred, but this was again reduced, after which the patient made a good recovery.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Nerves of the Uterus.—By M. Boulard.

While the discussion on the existence or non-existence of a special uterine nervous system is yet fresh to the memory, it may not be uninstructive to give an outline of the observations of an anatomist unconnected with either disputant. M. Boulard has recently read a memoir to the *Societe de Biologie*, in which he says:— "The results of our dissections have constantly been opposed to those of Dr. Robert Lee, while they have been completely in accordance with those of Mr. Snow Beck." The conclusions of the memoir are as follows:—

1. The nerves of the uterus are derived from the hypogastric plexus of the lower sacral nerves and from the inferior mesenteric plexus, and are distributed in such an inextricable mesh that it is impossible to determine whether they originate in one system or the other. Nevertheless, we have constantly seen on the right side a nerve of considerable size coming out of the lumbo-aortic plexus, and traversing the broad ligament to ramify on the uterus, ligaments, and fallopian tubes, sending also a few filaments to the ovaries. This nerve anastomoses on the sides of the uterus with one or two branches from the hypogastric ganglia or plexus.

2. The uterine nerves are few in number, and of extreme tenuity.

3. These nerves do not increase in size during pregnancy. This the author has ascertained by dissecting, side by side, the uterus of a child of 12 years old, and that of a woman in the last stage of pregnancy. The only difference appears to be in the width of the interspaces between the filaments; there is no difference in the size of the filaments themselves.

4. The neck of the uterus appears to the author not to be entirely deprived of nerves; he thinks that he has traced a filament into the os uteri.

6. He has never discovered an uterine plexus; but regards the appearance, so called, as deceptive, and to be produced by the peculiar interlacement of venules, lymphatic vessels, and muscular fibres. — *Gazette Médicale*, Aout. 16.

PRACTICAL MEDICINE AND PATHOLOGY.

Abscess of the Liver bursting into the Pericardium.— By Dr. Humble.

Instances in which abscess of the liver makes its way through the lungs are sufficiently common, and in many cases terminate favourably, but it seldom occurs to the physician to witness a case similar to the one below related.

A man, aged 36, formerly a soldier, complained of headache, languor, and general uneasiness, with considerable thirst. His tongue red and dry; pulse 112; respiration easy; no cough; skin hot and dry; bowels confined. He was ordered a dose of castor oil, and a diaphoretic mixture. Next day his symptoms were much relieved, but his tongue was still dry, and slightly furred. He was ordered six grains of mercury with chalk at bed-time, and to go on with the mixture. He continued to improve, his febrile symptoms gradually declining, until the 22nd day of August, when he seemed much depressed in spirits, but complained only of debility. His skin was cool; tongue clean and moist; pulse 90, soft and regular; his bowels open. To have wine three times a-day, and full diet.

On the 25th he was sitting up; his appetite was good; he was much more cheerful, and feeling better in all respects, but at eight o'clock next morning he suddenly died. He was examined ten hours after death. The heart was found slightly hypertrophied, and its cavities dilated; all the valves were healthy; the serous surfaces of the pericardium were coated

extensively with coagulable lymph, and its cavity contained a large quantity of pus, derived apparently from a communication through the diaphragm with a cavity in the substance of the liver, which contained purulent matter. This cavity also communicated with the inferior lobe of the right lung, which was hepatized, and contained various sinuses running into each other. The upper lobes of this, and the whole of the left lung, were healthy in structure. The abdominal organs, excepting the liver, were healthy.—*Medical Gazette*, September 13, 1851.

Successful Treatment of Croup by Cauterization of the Larynx.—By Dr. Townshend.

The author was called to a little girl, aged five years and a half, who had been suddenly seized with croupy breathing shortly before. She was treated with Dover's powder repeatedly during the day, and the room was filled with vapour by immersing heated irons occasionally in a tub of hot water. Cauterization with nitrate of silver was practised at noon and in the evening without much relief; at twelve P.M., the croupy respiration increasing, the patient was fast sinking from suffocation; the pulse intermittent; the caustic was more effectually applied. Expectoration of a portion of the membrane, an inch in length, and half an inch wide, followed in fifteen minutes; relief was immediate; ether was also inhaled with a happy effect, producing a pleasant sleep. Several portions of membrane were expectorated during the night and the following day, and the respiration became natural. No patches of lymph upon the tonsils or fauces were discovered. At this time, seven days from the attack, the patient is playful, with a good appetite. Expectoration purulent and bloody. Has had no return of dyspnœa, but still speaks only in a whisper.—*American Journal of the Medical Sciences*, July, 1851.

Treatment of Bright's Disease.—By Dr. Hughes Bennett.

The author observes, in an admirable clinical lecture on this disease, that the main remedies for the fundamental disease are,—general and local depletion, counter-irritation, diaphoretics, diuretics, and astringents. In acute cases general depletion is essential, if there be general reaction. Counter-irritation of the loins is probably too little resorted to. It is improbable that any benefit can be derived from depletion or counter-irritation in stearosis, uncomplicated by inflammatory desquamation. In all cases, acute or chronic, stearotic or inflammatory, diaphoretics are of essential service. The best are Dover's powder, the warm bath, warm clothing, and, for convalescents especially, a moderately warm climate. Diaphoretics have always appeared most serviceable when they are so given as to excite a gentle perspiration during a part of the night. Diuretics are seldom necessary for the fundamental disease; but they are sometimes advisable when the urine becomes very scanty, even although there is no dropsy; and they are undoubtedly the most certain and speedy remedy when the dropsical effusions are considerable. I am convinced that the fears entertained by some of injury being produced by the stimulus of diuretics on the kidneys are visionary. In *one* case only have I ever witnessed any harm, and in numberless cases I have seen dropsy quickly removed by diuretics, not only without increase of the other symptoms and secondary affections, but likewise with manifest improvement in them all. The stimulus caused by diuretics may well be supposed to differ entirely from the peculiar irritation which gives rise to either inflammatory or stearotic desquamation; and in that case the induction of the one may not of necessity tend to induce, keep up, or increase the other. Besides, is there no likelihood of advantage from diuretics sweeping out the tube-casts and other matters obstructing the uriniferous tubes? The best diuretics in the author's experience are, digitalis, squill, and bitartrate of potash, taken simultaneously. Nitrous ether, broom tops, acetate of potash, or oil of juniper, have seldom succeeded in his hands when the other three have failed; but after all these have failed he has seen diuresis speedily established by Holland's gin. He doubts whether astringents, even in chronic cases, are of the benefit we might expect. He has seen a few cases in which the albuminous impregnation ceased under the use of acetate of lead, or under that of gallic acid; but the good effects have not been so frequent as to entitle him to speak positively in their favour.

Speaking of the treatment of secondary diseases, he says, that it "does not materially differ from that which is applied to the same diseases in other circumstances. All of them are more difficult of cure when secondary to Bright's disease. Inflammations must be treated with activity in the usual way. I repeat that, after frequent careful watching, I can find no objection to the use of diuretics for removing dropsy, but quite the reverse. But in this affection we should avoid the cathartic plan, as being apt to excite permanent diarrhœa; and mercury should be shunned as a mercurial, on account of the facility with which, in this disease, it produces excessive action. The best remedy for diarrhœa, which so often proves troublesome, and sometimes dangerous, in Bright's disease, is the Edinburgh lead and opium pill, in the dose of five or ten grains twice, or even thrice, a day, to which may be added, in severe cases, a fatty suppository of muriate of morphia. Vomiting may be sometimes removed by bismuth, but more frequently by morphia, hydrocyanic acid, creosote, pyroxylic spirit (medicinal naphtha), chloroform, or little fragments of ice; and when these fail, a blister over the epigastrium has sometimes succeeded. It is not necessary for me to say anything of the treatment of other secondary diseases. In all cases stimulant liquors should be used with caution; but they are sometimes unavoidable when the exhaustion is great. The diet in the acute form must be low, light, and farinaceous; but in the chronic form a moderate allowance of nutritive easily-digested food, with a moderate use of liquids, has always appeared to me the preferable diet, when the patient can take it."—*Edinburgh Monthly Journal.*

SURGERY.

Opinions regarding Strictures of the Urethra.—By Mr. Guthrie.

1. That a hard and elastic, or an intractable stricture is never permanently cured by dilatation, or

by the application of caustic, although it may be materially relieved by the regular periodical use of a dilating instrument.

2. That the division of an old, hardened, or elastic stricture through the perinæum is not unusually followed by a permanent cure, although it is always attended by immediate relief. The disease being apt to return unless a solid sound or a catheter is occasionally passed to prevent it.

3. That the operation of dividing the perinæum and urethra in such cases is sometimes attended by severe hæmorrhages, by fever, and is occasionally followed by fistulous openings, giving rise to much inconvenience.

4. That such division does, in some instances, effect a permanent cure.

5. That the division of the urethra through the external parts should never be attempted in any portion of it anterior to the bulb, such operation not being necessary; for the narrowest stricture of the pendulous or moveable part may always be divided internally with much less comparative danger than by the external incision, inasmuch as the instrument can be guided through this part by the finger and thumb of the left hand of the surgeon with a certainty almost unerring.

6. That the stricture considered by all surgeons as the most important and difficult of cure—viz., at the termination of the bulbous portion of the urethra—may always be divided, when impassable, by a *straight* instrument, and in general more easily than by a *curved* one; the use of which is founded on the erroneous belief that the stricture is situated in the membranous part of the urethra, instead of being, as it is, anterior to it.

7. That the division of a stricture should, if possible, be effected by an instrument passed through it, and cutting from behind forwards, rather than from before backwards, although a combination of both methods will frequently be necessary to ensure success.

8. That the division of a stricture by these means will not always ensure a permanent cure if more than the mucous membrane is implicated, unless such parts be divided also.

9. That in cases of intractable stricture, the mucous membrane, the inner layer of involuntary muscle, and the elastic tissue external to it, should be divided, when the operation is done from within, but not the outer layer of muscular fibres, which should remain as a barrier between the stream of urine and the common integuments of the external parts—an accuracy of division not always to be attained: whence, perhaps, the difficulty of effecting a permanent cure.

10. That when a permanent cure is effected in these cases, the divided elastic wall of the urethra is not reunited by a structure exactly similar to itself, but by common areolar tissue, rendering the part more dilatable under the pressure of the stream of urine; the formation of which dilatation can be aided during the progress of the cure by pressing on the divided part with the point of a solid instrument passed daily for the purpose of preventing, if possible, that contraction which always takes place during the process of cicatrization; a proceeding which cannot be advantageously adopted when the parts are divided through the perinæum, lest it should encourage the formation of a fistulous opening, to which there is always a tendency.

11. That in cases of intractable stricture accompanied by one or more fistulous openings in the perinæum, in *young persons*, or of middle age, the operation through the external parts, or along the urethra, may be resorted to at the pleasure of the surgeon with an equal chance of success, provided the division of the obstruction or bank preventing the free passage of the urine be effectually divided, the *sine quâ non* of the operation.

12. That the operation within the urethra should always be preferred in *elderly* persons, particularly if somewhat stout or fat, as less likely to create severe constitutional disturbance; and if this operation should fail from any cause, it by no means interferes with the due performance of the other through the perinæum, which in serious cases then becomes imperative, as the last resource capable of giving relief.—*Lancet*, June 7, 1851.

Treatment of Obstinate Ulcers by the Internal Use of Tincture of Cantharides.—By J. Tart, Esq.

In a case of extensive ulceration in a broken constitution, after the failure of various plans of treatment, Mr. Tart gave ten drops of tincture of cantharides three times a day, with marked benefit. In three days from the commencement the sores began to contract, healthy lymph appeared round the edges, and vivid granulations started up. In a fortnight the ulcers were quite healed. On this case the author remarks:—

"Such was the progress and issue of a case that had baffled every previous treatment employed. It affords one of many examples I could bring forward of the great utlity of cantharides in indolent ulceration, dependent either upon atony of the engaged parts, or system generally,

"In 1845, while resident in Burmah, my attention was directed to the treatment of the ulcers met with in that country, and which had long been found difficult to heal by different medical gentlemen stationed upon that coast. I drew up a paper, exhibiting the appearances presented by the different ulcers, and the states of of constitutional derangement with which they were identified, and in which I had employed the tincture of cantharides with marked success. The paper alluded to, backed by several cases treated by different medical friends, was forwarded to the Madras Medical Board, who ordered it to be circulated throughout the medical service of the Madras army.

A few extracts from the paper here referred to will show the characters of the ulcers where I found the tincture of cantharides useful:—

1st. "Where the granulations were exuberant, but pale, weak, and flabby.

2nd. "Where there was deficiency, or total absence of granulations, the ulcers being deep and scooped out, with raised and indurated edges.

3rd. "Where the granulations were not defective, but cicatrizing irregularly, sometimes in the centre, at other times on one side, the lymph which was thrown out and organized one day being absorbed the next.

"It was further remarked that their indolent character was to be referred to morbid states of the system, varying from little perceptible deviation from health to the different grades of anæmia. It was difficult at first to assign the cause of this indisposition to heal, in sores which presented themselves in subjects where the

general health was little impaired, and this was increased on finding that they did not yield to the exhibition of remedies known to exercise a beneficial influence upon such ulcers. It was from observing the ineffective attempts at reparation, which I occasionally witnessed in the different cases that came before me, that suggested the belief of the primary derangement to be owing to deranged circulation of the affected part, and the blood being deficient of, or not elaborating, plastic lymph of sufficient quantity or quality necessary for the healthy granulating process."

Tracheotomy in Croup; Chloloform used.—By Henry Smith, Esq., F.R.C.S.

The chief value of the case narrated by Mr. Smith, consists in its being the only instance in which chloroform has been used in the operation of tracheotomy. The case was one of inflammatory or exudative croup occurring in a child aged four years. By the use of chloroform anæsthesia was safely induced, and it was observed that the breathing became more free and tranquil. Whilst insensible, Mr. Smith opened the trachea, on which mucus and false membrane were expelled. The child appeared to be going on favourably for some hours, but next day it became gradually comatose and so died.

On examination, the fauces were found covered with exudation, and the trachea lined with false membrane, which extended even to the larger ramifications of the bronchial tubes.

Dr. Snow's reasons for not refusing to use chloroform in this and similar cases are so sound, that we transcribe them. In a letter to Mr. Smith, he says:—"I believe that many medical men would have objected to the employment of chloroform during tracheotomy, or a case in which extreme difficulty of breathing existed, but the following are the reasons which induced me to recommend it, when you asked my opinion on the subject:—1st. Chloroform in moderate quantities does not diminish the strength of the respiratory movements. 2nd. I have ascertained by experiments on animals, that a larger quantity of air is not required to support life under the influence of chloroform and other narcotics than in ordinary circumstances; but, on the contrary, that they can actually subsist on less air than in the normal state. And 3rd, the struggles of the child that would be occasioned by pain and fright, if the operation were performed in the conscious state, would cause an increased demand for breath, and be a real source of danger.—*Medical Gazette*, August 29.

MIDWIFERY.

Cæsarean Operation; Successful to Mother and Child. By Mr. Poland.

The patient was a woman who had borne five children, but who subsequently to her last confinement appears to have become the subject of carcinoma uteri. She was admitted into Guy's Hospital, under Dr. Oldham, being in the seventh month of pregnancy. On the 2nd of July labour pains became manifest, and examination being made, no os uteri could be felt. The pains continued without the least effect upon the uterine orifice, which was insurmountably closed by malignant growths; and under these circumstances the Cæsarean operation was suggested by Dr. Oldham, and performed in the usual manner by Mr. Poland, chloroform having been previously administered. The child was extracted living, and the mother expressed herself as having been entirely unconscious of the operation.

On the ninth day the sutures were removed; and two months after the operation the patient is reported as in a satisfactory state. The child is thriving.—*Lancet*, September 5.

On Bandaging the Abdomen after Delivery. By Mr. Kesteven.

One of the commonest practices, and in general medical opinion one of the most useful, is that of bandaging the abdomen after delivery. The author, however, believes that it is "not only unnecessary, but in many cases absolutely injurious; its utility being quite other than is usually stated, while any advantage which it offers are to be gained by its employment at a later period than is generally directed."

The objects alleged to be gained by the application of the roller are:—1. To promote the contraction of the uterus. 2. To lessen the severity of the after-pains. 3. To prevent hæmorrhage. 4. To prevent syncope. Lastly, to protect the patient against the consequences of sudden alteration of the balance of circulation, by which syncope, inactivity of the uterus, and hæmorrhage, have been produced.

In examining these reasons, the author concludes that all the ends proposed may be accomplished without the roller, and that the custom is "more honoured in the breach than in the observance." He does not, however, altogether discountenance bandaging the abdomen, but restricts its use to a later period than is generally advised. The proper period is, he thinks, when the uterus has firmly contracted, and the patient is got comfortably "to bed." Before this he considers it an useless encumbrance.—*Medical Gazette*, Sept. 12, 1851.

NOTICE OF THE LATE JONAH WILSON, ESQ., OF HUNTINGDON.

The following biographical notice of the late Mr. Wilson, by M. Foster, Esq., of Huntingdon, by whom it has been forwarded to us for insertion in the *Journal*, and we have much pleasure in acceding to the wish of our respected Associate:—

Mr. Wilson was born at Oswaldkirk, Yorkshire; was apprenticed to his maternal uncle, Mr. Wass, of Thirsk, in the same county, who appears to have been a person of great energy of character, and a very respectable practitioner of medicine; Mr. Wilson always spoke of him with emotions of pleasure and grateful satisfaction. For a short time he studied at the Borough Hospitals, and for three months at Edinburgh, and soon began practice at St. Neot's, Huntingdonshire, but he found his deficiencies so great, and his confidence in himself so slight, that in the course of a few months he resolved to return to hospital practice. He became an assistant apothecary under the late Mr. Stocker, of Guy's, and

prosector to the late Sir Astley Cooper. For five years he studied and laboured with the most unwearied diligence and perseverance, at the expiration of which period he commenced practice at Huntingdon, entering into partnership with Mr. Desborough, whose health had so much declined as to induce him to relinquish the profession. Mr. Wilson rapidly rose in public estimation; his accurate acquaintance with anatomy and surgery, acquired in that celebrated school under Sir Astley Cooper, when in the full vigour of his splendid career; his thorough knowledge of pharmacy, as evinced in his work "Pharmacopœia Chirurgica," which he committed to the press soon after his arrival at Huntingdon, and his keen powers of observation, retentive memory, and masculine understanding, render it no marvel, that in the then low state of medical and surgical knowledge, particularly the latter in the provinces, he should the first year have trebled the amount of returns, and in the course of a few years attained the highest eminence, and for many years commanded the most lucrative practice in the neighbourhood, both in general practice and in consultations with all his medical friends around. About 20 years since, the premature death of his eldest son, intended for the profession, gave so powerful a shock to his system, that it was with difficulty he could command his attention, hitherto unremitting, to his professional duties. Attacks partaking of the gouty diathesis, frequently disabled him altogether, and in a few years he gradually withdrew from the arduous engagements of his profession. Three years ago he left Huntingdon to reside with his affectionate son, and ended his days in peace, on the 13th of June, 1851, in the 73rd year of his age.

Mr. Wilson's intimate knowledge of the materia medica, combined with his ardent attachment to classical, medical, and general literature, gave him great facility in prescribing. For elegance of diction, exact, and dignified design of each element, together with a comprehensive grasp of the combined and main action of the whole, his prescriptions were considered *models* well worthy of notice and imitation, being as free from the multitudinous complexity of the ancient school, as from the raw simplicity of the modern. Amongst our medical classics, Mr. Wilson was particularly partial to "Gregory's Conspectus Medicinæ Theoreticæ," generally reading it through once in the course of the year; "Heberden's Commentaries" was scarcely ever out of his sight; Von Swieten and Sydenham also were much admired by him. Of English authors, his great favourite was Fordyce on Fevers, a work he was ever lavish in praising. He thought the more modern authors far below them in the closeness of their observations, always excepting "Copland's Dictionary," a work he, alas! lived not to see completed—which is a lot, apparently, likely to befall many of us.

Mr. Wilson, ever ready to perform an operation when absolutely necessary, even more fondly admired and relied upon nature's great powers; he was remarkbly successful in the medical treatment of surgical cases; his knowledge of midwifery, in all its mechanical forms and vital powers, was complete; few men of his day were his equal. The first edition of his "Pharmacopœia Chirurgica," was dedicated to Sir Astley Cooper, and was published November 2nd, 1809; the second edition March 2, 1811. It soon passed through the third, and now, for many years, has been out of print; it was highly esteemed at the time of publication, and for a long time was a text book for the practitioner of surgery. I have had the testimony of the most eminent men of our profession, that the "Pharmacopœia Chirurgica" was always on their study table—a book of constant reference. Mr. Wilson, like the "Sexagenarian," correspondent of this *Journal*, was no diplomatist. It is true the degree of M.D. at Aberdeen was offered to him, but he perseveringly refused to accept it. He was not a member of the Royal College of Surgeons; in his early days that honour was not much sought after, and writhing under the pangs of "res augusta domi," and with the advice of his warm-hearted friend, Sir Astley Cooper, he launched forth on his career of success and usefulness *without* that now imperatively necessary and valuable qualification.

Huntingdon, July 14, 1851.

Correspondence.

NECROSIS FROM LUCIFER MATCHES.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—The Provincial Medical and Surgical Association affords a valuable means of concentrating into a focus the information scattered through the provinces on any subject which may engage the attention of its members. It further may serve to unite the exertions of the profession, in carrying out any measures which may be conducive to the public good. In both these ways the Association may become an important sanitary organ, and as such well deserve the respect and consideration of the nation. On many subjects the information derived from the manufacturing districts is pre-eminently valuable, and the medical men who reside in these places can alone represent the wants and necessities of a large class of the community. There is, perhaps, no more important study in respect to the *etiology* of the diseases found in public hospitals, than that of the influence of the trades. They who will carefully inquire into these matters, and be at the trouble of repeatedly watching the artisan at his work, will be able to trace the sources of many obscure complaints, and will be led to abandon that routine manner of accounting for diseases which contents itself with vague phrases and surmises. They will also not rest satisfied with the *mere treatment* of a disease, which must return as soon as the patient resumes his employment.

My present object is to direct the attention of the Provincial Association to the evils arising from the manufacture of lucifer matches, and request from that body such information as its members may have to afford. I do not presume to ask the lengthened detail of cases, as this would involve considerable trouble, but simply for brief replies to the following questions:—

1. Whether any case or cases of necrosis, from this cause, have come under the notice of any member?

2. After what period of employment?

3. Whether immediately arising from such employment, or after any and what cessation from it?

4. At what manufactory they occurred?

5. The result of the case?

6. Age of the patient and peculiarities of his condition; whether scrofulous, or having carious teeth?

7. If any preventive measures are taken at the manufactory, and what?

My reason for proposing the third question is, that the necrosis produced by phosphoric fumes may arise at a considerable period after removal from the cause. A case is related by Dr. Strohl, of a young woman who had consulted him in June, 1845, who had been employed five years in a manufactory of lucifer matches; she had been accustomed to dip the matches in the preparation, and during all that period she had experienced no inconvenience. She then left the establishment and undertook another employment. *In three months afterwards* she experienced pain in the upper jaw, which was succeeded by swelling and abscess of the gums. Eight teeth in succession became rapidly carious and were removed. When first seen by Dr. S. she had been eighteen months away from the manufactory. In many other cases the patients have left their occupation apparently suffering from a trifling pain in the face, though afterwards they have had extensive disease of the bones. In another case related by Dr. Strohl, a female, aged 22, who had been employed in the same manufactory as that last mentioned, continued for two years in good health, and until two months previous to her quitting the occupation. Afterwards the teeth became carious, and a fœtid suppuration arose.

The fourth question is important because the cases which have occurred have mostly arisen from particular manufactories; and consequently it is to be supposed that deficient ventilation may have an important influence. Hence the necessity of the supervision of such manufactories, on which subject I have addressed a letter to a distinguished philanthropist, the Earl of Shaftesbury.

It seems that the Austrian Government have not thought this subject unworthy of consideration, but have ordained the observance of certain precautions which have been recommended by a medical commission. The health of artisans has been singularly neglected in England, where benevolent schemes are generally supported with equal zeal and munificence. Perhaps it may be that the profession itself has been wanting in alacrity to make known the baneful results of some forms of employment, or has been deterred by a fear of giving offence, where patronage was concerned. Such fears, I need not say, are altogether beneath the consideration of an honourable and humane profession.

For the use of those who have not already paid attention to the necrosis which arises from phosphoric fumes, I may briefly notice some of the authorities which may be consulted. Mr. Stanley, in his work "On Diseases of the Bones," alludes to this affection; Mr. Taylor in his work "On Poisons;" the *American Journal of Medical Science* for 1846, p. 525; *Chamber's Edinburgh Journal*, July, 1846; the *Lancet*, for 1847, vol. 53, p. 203; the *Lancet*, for 1849, [two papers, see the index]; *La Nouvelle Encyclographie*, Aout., 1850, p. 219. I believe there are various German pamphlets on the subject, and some memoirs on it have also been addressed to the French Royal Academy of Sciences; one by M. Roussel, in February, 1846, and another by M. Sedillot, of Strasbourg, in March, 1846.

I have the honour to be, Gentlemen,

Your obedient servant,

JAMES BOWER HARRISON.

Higher Broughton, Manchester.

ON THE

EXTERNAL USE OF NITRATE OF LEAD.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—As I am not aware that the nitrate of lead has ever been brought under the notice of the profession, except as a disinfectant, I venture to send you the following account of some of its applications to other purposes, in some of which it has supplied a desideratum, and in all has succeeded to the fullest extent.

Two years ago, when, in consequence of the approach of the cholera, the attention of the public was directed to the removal and destruction of noxious gases and odours, a number of so-called disinfecting agents was brought forward for this purpose, and among them the nitrate of lead.

Finding, from numerous trials, that it fully bore out all the encomia that were given it for correcting bad smells, and far exceeded the preparations of chlorine, in utility, for these purposes, by the advantage it possessed of being perfectly inodorous, I was induced to try it as an antiseptic for the preservation of recent morbid preparations. I perceived, however, that though the nitrate of lead, in solution, effectually checked decomposition and removed all fœtor, yet it became deposited upon the substance in the form of a white precipitate, that penetrated the surface and combined with the tissue of the preparation, thus spoiling its appearance, and destroying its utility as a representation of the effects of disease. Reasoning, therefore, on this property of the nitrate to combine with and harden the tissues with which it is brought in contact, it occurred to me that it would form an excellent lotion for the cure of fœtid discharges, not only by removing the smell, but by checking the secretion by its astringency.

The first case in which I used it with this intention was that of a lady, whose lochia were so offensive as to scent the whole house, and nauseate even the nurse. It was used as an injection, and the third application effected the complete removal of the fœtor.

I have also used it with success as a lotion for sore legs when in a sloughy and indolent condition, and I find that it soon restores them to a healthy state, inducing a proper secretion of pus, with firm granulations on the surface of the ulcer.

I have not yet used the nitrate in acute gonorrhœa, but it acts admirably as an astringent in gleety discharges, as well as in those of cancer uteri, whether sanious or purulent. In short, as a lotion it is as extensively useful as the diacetate of lead, while it is superior to that preparation by its disinfecting property.

I have not, however, ventured to use it as a collyrium, for fear of the deposit of lead affecting the transparency of the cornea.

In chronic cutaneous diseases, the most remarkable instance of its efficacy has been afforded in a case of eruption, of a kind of rupia or impetigo of five years' standing. The complaint broke out on the vertex of a woman, aged 50, and, leaving its original site, it has gradually crept down over the forehead, nose, and cheeks, to the level of the mouth. The primary form of the eruption consists of inflamed flattened pustules slightly elevated above the surrounding skin, which discharging their contents, form thick, rough, yellowish crusts, or scabs, fissured in all directions, like those of crusta lactea, which, firmly adhering and growing from their base, like rupia, for a longer or shorter time, fall off at last, leaving cicatrices of various shapes, exactly like the seams and pits of small-pox. The patient came under my care some months ago, when I tried many remedies, both internal and external, in vain, quinine being the only one that produced any good effect, and this not permanently. As the skin around the sores and where they had healed seemed in a state of hypertrophy, the papillæ projecting in many places as in elephantiasis, it occurred to me that the best way to check the progress of the disease would be to apply some penetrating astringent to the surface; and with this view I ordered a lotion of the nitrate of lead, with quinine internally. In the course of a few days the eruption ceased to make any progress, the crusts began to fall off, and the skin to lose its redness and swelling; and in a fortnight every sore was healed, though the face and forehead remained still seamed with scars. There has been no fresh breaking out for some weeks, though, as the nose is still red and swelled, I have ordered the continuance of the lotion.

The formula I generally use is the following:—R. Plumbi. Carb., scr. j.; Acid. Nitr. dil. q. s. ad. solvendum; Aquæ. dist., lb. j., M. Fiat. Lotio bis terve indies assidu utenda.

In the above case the lead was increased to half a drachm. The best test for the degree of strength of the lotion is the production of a *slight* smarting, which soon subsides. In the hope that the merits of this preparation will become readily known to, and fully tested by the members of our Association, I request the favour of the insertion of the above-mentioned particulars in the *Provincial Medical and Surgical Journal*, and remain, Sir,

Your obedient Servant,
T. OGIER WARD.

Kensington, Sept. 18, 1851.

THE RECENT OUTBREAK OF CHOLERA.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—In one of the daily papers some little time ago, (about the middle of August), I saw a paragraph copied from a Birmingham paper, containing an account of reported cholera in that town, calculated to give rise to unnecessary alarm. About the period alluded to, I had the charge of a district of the Greenwich Union for about three weeks, the weather for a few days was unusually depressing, and several cases of aggravated "English cholera" came under my notice. Some assuming many of the characters of the epidemic of 1849, and which I dare say were closely allied to the cases reported at Birmingham. One night, in particular, I was called to two cases, in a very filthy locality. I found both parties suffering with the following symptoms:—Constant diarrhœa; vomiting; cramp of the abdomen and lower extremities; pulse scarcely perceptible at the wrist; skin cold; voice husky; and thin watery evacuations, with scarcely any odour. These symptoms soon subsided under the treatment of calomel and opium, brandy, astringents, and hot applications.

During the epidemic of 1849, I had the charge of a district of the West London Union, where cholera raged as badly, or I may say worse, than in any part of the city. I believe I witnessed nearly 1,000 cases, a considerable number of the most aggravated form; but I must confess I did not see the disease *cut short* in one instance after it had assumed the symptoms above described. At that period, too, I had the advantage of the advice of several leading physicians connected with the hospitals; all were desirous of testing their favourite remedies, but I am not yet persuaded that the sufferers were much benefitted by the various means resorted to. It appeared to me if the patients' constitution was pretty good, and the locality favourable, there was some fain hope that he might "weather it," to use a familiar expression. It is my opinion that the disease recognized in this country as cholera, or "English cholera," has assumed, since the epidemic of 1849, *many symptoms closely allied to the Asiatic*, but that the disease widely differs in severity, real character, and result.

I am, Sir, your obedient Servant,
EDWIN BISHOP.

September 8, 1851.

UNRESTRICTED SALE OF LAUDANUM.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—If the subject I am about to mention appears to you of sufficient importance to be inserted in the *Journal*, I shall feel much obliged by your bringing it in that way under the notice of the Association, or in any way you think proper.

The use of *opium* for its intoxicating effects, is becoming daily more general among the humble but useful classes of society, and the ease with which it is obtained from the retailing chemist and druggists, tends to propagate the mischief. Only two days ago my attention was directed to one among very many instances that have occurred to me, by my good neighbour Mr. Sweet, (a member of our Association,) who showed me a *pint* of laudanum, with the name of the chemist from whom it had been purchased, at Birmingham, for two shillings and eightpence. It is true, "poison" was marked on the label, but this frightful quantity was

sold to a single individual, non-medical, and to whom the vendor was a stranger.

Mr. Sweet accidentally met with it, where it had been brought as a present to a poor person, just as brandy or tea would be brought, and with as little precaution; and he wisely and kindly prevented further mischief by his timely interference.

Whether the Legislature, with a due regard to the "salus populi," should be called upon for some further enactment, after what has been done in regard to arsenic, the Association, (the members of which constitute the best judges of the evils arising from the indiscriminate use of laudanum,) can decide. No better court of appeal in such a case could be found than that to which these remarks are now submitted.

A. W. DAVIS, M.D.

Tenbury, July 23, 1851.

ON MENTAL ALIENATION.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—Mental alienation has been defined by Esquirol as a cerebral affection, ordinarily chronic, characterized by disorders of sensibility, of intelligence, and of the will. It is to this form that I more particularly submit my remarks.

It has been said, like wine, to develope the private feelings, sentiments, and disguised ideas of its subject—in fact, to unlock the closet of the human mind; it is undoubtedly true, that in many instances, the moving springs of conduct, and the probable reason which led to the outbreak of the malady, can be traced.

It is true that, in a large establishment, an epitome of the world can be found—the same ideas, the same envies, the same passions, the same mixture of misery and happiness! But here the effects are more decidedly marked, because there is none, or but little restraint placed upon actions, as the passions have become stronger than the reason. Even in the limited number of a small private establishment, marked differences occur; all the shades of human desires and aspirations are discernable; very frequently, though, a more guarded mode of conduct may be maintained, the result, as I apprehend, of the facility afforded of stricter observation This will seldom deceive the experienced eye.

I am not writing an essay; and it is by no means my intention to go through the symptoms of mental alienation; generally speaking, there is some defect in one, two, or all, of the external senses, but almost invariably egotism. The inmates pay very little attention to one another,—their own wants, wishes, condition, and comforts must be immediately attended to; and often jealousies arise from what may be considered a preference shown to another.

In regulating all this, in endeavouring to bring better sentiments into play—to restore to reason distorted intellect, how often is the manager of a private establishment disturbed and prevented by the interference and conversation of injudicious friends, and by the wrongly-timed observation and directions of those who doubtless consider they are moving in their path of duty, but who appear to reason from general principles on individual cases. Who can so well observe the bearings of a patient's mental infirmity as one who sees frequently, and writes down regularly, the different phases of the disease.

Again, it is seldom that a patient is placed under private care at the first outbreak; most frequently an attendant is procured, and medical means are resorted to. This may occasionally answer in violent cases, and in some first instances, but it is more generally attended with false hopes, much anxiety, and increased expense. At length a private establishment is chosen. By this time the mental affection has taken deep root, and the bodily condition of the patient not improved by various modes of treatment. In difficult cases it is probable that some time must elapse before the key-note of the mind can be obtained. Upon many subjects the patient may talk well and compare justly; and a mistaken notion emanates as to any actual insanity prevailing. Of this, frequent examples are enumerated in all books treating upon the subject. Nevertheless, I consider this form of the disease is frequently lost sight of, and that present appearances are not unfrequently admitted as the standard of mental health.

Many suicides have been committed in consequence of this error.

I remain, yours obediently,

E. B.

Medical Intelligence.

HOMŒOPATHY AND THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The following requisition to the Council of the Royal Medical and Chirurgical Society is in course of being signed. We understand that it will be presented at the commencement of the Session in November :—

"We, the undersigned Fellows of the Royal Medical and Chirurgical Society, being convinced that the doctrines of homœopathy and mesmerism are utterly fallacious, and inconsistent with the facts of medical science, hold that they are unworthy to be professed, or in any way countenanced by members of this Society, the object of which is the promotion of a sound knowledge of medicine and surgery. We therefore request the Council to take this subject into consideration, with the view to prepare regulations whereby all homœopathic, mesmeric, and similar irregular practitioners shall be excluded from the Fellowship of this Chartered Corporation. And we hereby request the Council, with as little delay as possible, to summon a special general meeting of the Fellows to resolve on the same."

THE HOMŒOPATHS.

We understand that a motion was brought forward at the Medical Society of University College, to expel certain members who practise homœopathy.

THE SALE OF ARSENIC.

Mr. Sefton, druggist, of Accrington, has been prosecuted for not strictly obeying Lord Carlisle's Act. He sold the arsenic in the presence of a man who signed a book as witness; but he did not colour the mineral with indigo or soot, and the purchaser was under age. Mr. Sefton pleaded that he did not know it was necessary to colour the arsenic, and he thought the purchaser was of age. The Magistrates fined him £5 only, the full penalty being £20.

A NEW QUACKERY.

In Naumberg a man named Mahner is preaching the necessity of a new regeneration, not in the spiritual, but physical sense. He warns a sickly race that it must return to the lost state of "primitive health," or *Urgesundheit*, as the means of more fully enjoying life, and attaining a patriarchal old age. It is to be secured by a diet of bread and water, going barefoot, and letting the hair and beard grow; in short, making a nearer approach to man's original state in costume than the decencies or prejudices of modern society will altogether permit. On this topic he has been lecturing to a chosen few, but his doctrines do not seem to take, bread and water not being tempting, even with four-score years promised as the prize of self-denial. It is also said that the apostle does not fully act up to his own precepts, preferring a well-spread table and every variety of wine or beer to the pure element; but this may be a calumny of the hotel keepers. The German journals are perpetually turning up some eccentricity of this sort; to prepare or preserve health, the oddest "cures" are resorted to. A section of the public seems determined to escape the hands of the faculty, and die by some irregular process, rather than with the aid of medicine. In a single advertising sheet could recently be counted up a water cure, a grape cure, a milk cure, and a hunger cure; to these must be added another just getting into vogue—some of the former having had their day—it is the cure by muscular exercise, by which cripples from rheumatism are put through a course of gymnastics; and dancing is prescribed for the gout. These, however, are all merely cures or remedies; the "primitive health" theory is founded on a system of living which would literally make "man's life as cheap as beasts," without much prolonging it. As far as hair and beard go, many of the Berliners are meeting the Naumberg preacher more than half way.—*Lancet.*

QUEEN'S COLLEGE, BIRMINGHAM.

An influential meeting of the friends and supporters of the Queen's College, Birmingham, was held in the Town Hall of that town, on Tuesday, the 7th instant, on the occasion of the presentation by the Queen of Her Majesty's portrait to the institution, and the distribution of annual prizes to the students. In the absence of Lord Lyttelton, the Principal of the College, the Rev. Chancellor Law, Vice-Principal, presided. The following prizes were then distributed to the successful students by the respective professors of the several classes:—

Warneford Medals, Banks, Franks; Warneford Scholarships, Waller, Webb; Governors' Gold Medals, Russell, Rowland; Warden's Senior Theological Prize, Oakes; Medal in Anatomy, Russell; Certificate ditto, Coleman; Medal in Surgery, Webb; Certificate ditto, Russell; Certificate Practice of Physic, Banks, John Smith, æquales; Medal in Forensic Medicine, Franks; Medal in Midwifery Class, Webb; Second Medal ditto, Perry; Certificate of Honour, Stillman; Medal in Materia Medica, Harris; Certificate ditto, Franks; Medal—Botany, Harris; Medals in Chemistry, Franks, Wilkinson, æquales; Certificate, Cantrell; Book—Demonstrations, Franks; Law Professor's Prize, Suckling.

PRELIMINARY EXAMINATION AT APOTHECARIES' HALL.

We are happy to observe that the remarks which were made some months since in the *Lancet*, upon the propriety of the junior members of our profession presenting themselves for the preliminary examination in classics and mathematics at Apothecaries' Hall, have been so warmly responded to. We are informed that nearly one hundred candidates have entered their names for this trial; and, as will be perceived, the Examiners have found it necessary to commence their duties three hours earlier than was originally intended. As it will be utterly impossible to conclude the examinations in one day, the proceedings are to be resumed on the Monday and Tuesday following.

It has been intimated to us that the Greek part of the examination will, upon the present occasion, be limited to the Gospel of St. Luke; but that, if any candidate should object, upon religious or other grounds, to the New Testament, he may be examined in the first book of Xenophon's Anabasis, if he prefer it.—*Lancet*

APPOINTMENTS.

Military.—83rd Foot: Assistant-Surgeon Edwd. Touch, M.D., from the staff, to be Assistant-Surgeon, *vice* Innes, who exchanges. Hospital Staff: Assistant-Surgeon John Henry Kerr Innes, from the 83rd Foot, to be Assistant-Surgeon to the forces, vice Touch, who exchanges.

Naval.—Surgeon, Thomas R. H. Thompson, M.D. (1851), to be Surgeon-Superintendent of the *Marion*, convict ship. Surgeon, Frederick W. Le Grand (1839) to be Surgeon-Superintendent of the *Marion*, convict ship, in the room of Thomas R. H. Thomson.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted members on Tuesday, the 30th ultimo:—Dr. Barron, St. Thomas's Street, Southwark; Dr. Habershon, Finsbury Circus; Dr. Parker, London Hospital. Also Dr. Thornton, Norwich, was admitted an extra-licentiate.

ST. GEORGE'S HOSPITAL.

The annual distribution of prizes took place in the Board-room of the hospital—the Right. Hon. Sir F. Pollock, Lord Chief Baron of the Court of Exchequer, presiding.

In addition to the scholarships, the following prizes and certificates were presented by the Lord Chief Baron, with some appropriate remarks with each:—

Anatomy, Senior Class: Prize, Mr. George Nayler; certificate, Mr. W. J. Williams. Junior Class: Prize, Mr. Oscar Byrne; certificates, Mr. G. Y. Hunter and Mr. J. Penny.—*Physiology:* Prize, Mr. J. R. Davern; certificate, Mr. J. S. Dodd.—*Botany:* Prize, Mr. W. R. Cornish; additional prize, Mr. J. Penny.—*Chemistry:* Prizes, Mr. W. R. Cornish and Mr. J. Penny.—*Practical Chemistry:* Prize, Mr. Wyndowe; additional prize, Mr. C. Royston; certificates, Mr. W. Jane and Mr. Jeckell.—*Materia Medica:* Prize, Mr. J. Penny: certificates, Mr. W. R. Cornish and Mr. G. Y. Hunter.—*Medical Jurisprudence:* Prize, Mr. Bolton; certificate, Mr. Firth.—*Midwifery:* Prize, Mr. W. B. Harrison; certificate, Mr. C. Royston.—*Practice of Physic:* Prize, Mr. W. B. Stephens; certificates, Mr. H. V. Carter and Mr. Francis Day.—*Surgery:* Prize, Mr. H. V. Carter; certificates, Mr. Francis Day and Mr. W. B. Stephens.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 3rd inst.:—Charles Thompson Abbott, Nenagh, county Tipperary; Charles Coates, Leeds; Edward John Complin, Charterhouse Square; John Davies, Brecon; George Graham, Cootehill, county Cavan; Henry Joseph Herschel Griesbach, Millington, Yorkshire; Henry Hanks, Malmsbury, Wiltshire; Thomas Le Gay Holthouse, Australia; Thos. S. Hollingsworth, Leicester Square; Lawrence Francis Mahony, Bedford Square, East; Thomas Whitefield, Millman Street; Joseph Coleman Wright, Dublin.

SOCIETY OF APOTHECARIES.

Gentlemen admitted on Thursday, September 25th:—James Black, Chesterfield, Derby; Henry Walter Bucknill, Rugby, Warwick; William Hill Clarkson, Ledbury, Hereford; George Jonathan Mitchinson, Carrington, Boston.

Gentlemen admitted on Thursday, October 2nd:—Leonard George Boor, London; Charles William Chaldecott, Dorking, Surrey; William Henry Cutts, Chesterfield; James Harnett Dowling, Cerne Abbas; Henry Gramshaw, Gravesend; John Grabham, Rochford, Essex; Francis Nuttall, Bury, Lancashire; James Parkinson Scowcroft, Bolton-le-Moors; John Joseph Whiting, Lynn Regis.

OBITUARY.

On the 2nd inst., at St. Margaret's Terrace, Cheltenham, John Baron, M.D., F.R.S.

BOOKS RECEIVED FOR REVIEW.

On the Pathological Anatomy of Bronchitis. By W. T. Gairdner, M.D., &c. Edinburgh: Sutherland and Knox. 1851.

The Journal of Psychological Medicine. October, 1851.

Monthly Journal of Medical Science. October, 1851.

London Journal of Medicine. October, 1851.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

SUFFOLK BRANCH.

Mr. C. R. Bree, of Stowmarket, having resigned his office of local Secretary to the above Branch, all letters in connection with the Suffolk Branch must be addressed to Dr. Kirkman, of Melton, Suffolk, who has been appointed his successor; it is therefore requested that all those gentlemen, (members of the Suffolk Branch), who have not yet paid their subscriptions for the current year, will be good enough to forward the same to Dr. Kirkman.

YORKSHIRE BRANCH.

Mr. W. Matterson, of York, has succeeded Mr. W. D. Husband as local Secretary to the above Branch; all letters and communications in connection with the Yorkshire Branch must be addressed to Mr. W. Matterson, and all members of that Branch who have not yet paid their subscriptions for the current year, are requested to transmit them to Mr. Matterson.

SHROPSHIRE BRANCH.

Mr. Humphreys, of Shrewsbury, has been associated with Dr. Drury, of that place, as joint local Secretary. All communications in connection with the Shropshire Branch may be addressed to either of those gentlemen, and by whom subscriptions and arrears will be received.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association at Worcester.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, September, 1851.

TO CORRESPONDENTS.

We have received several communications relative to the proposed prizes for "Hospital Reports," and in answer to these inquiries we beg to state, that the reports must be sent in to the Editors of the *Journal* during the year specified, but they may relate to cases of any previous year. They may also be sent in separately, or not, as most convenient, and with or without remarks. The hospitals in which they occur must be specified in the report, and also the name of the surgeon or physician in attendance.

Communications have been received from Mr. Humphry, Mr. Collett, Mr. Richardson, Dr. Cullen, Dr. Watts, Mr. Soloman, Dr. Whitton, W. E., Birmingham Pathological Society, Mr. Bainbrigge, An M.D. out of Practice, Mr. Wills, and Mr. Foster.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

LECTURE

ON THE

DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

BY DR. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

LECTURE VI.

THE PULSE; COMPLEXION AND HABITUS; POSITIONS OF THE BODY; MOVEMENTS; TEMPER AND HABITUDES.

THE *pulse* is much more variable in children than in adults, and naturally more frequent. I have frequently found the pulse 120 in infants, without any notable disturbance of the health; and it may happen that the same infants, at a different period of that day, will offer only 75 or 80 pulsations. The intermittent pulse occurred in my practice frequently, without any bad signification, in particular during the recovery from a severe and exhausting fever. Delicate children, and those disposed to convulsions, present also, occasionally, an intermittent pulse. A *slow and rare pulse*, below 60, almost always indicates a transudation in the head. Irregular and intermittent pulse is frequently connected with the preceding, and in similar circumstances.

Complexion and habitus.— The proportional development and relation of single parts to each other, or to the whole body,—certain forms and points which they present—impart to the whole a determined feature, which constitutes the *habitus* connected with a certain temperament and disposition to certain maladies. Before the sixth month we are frequently at a loss in distinguishing any special kinds of *habitus* of an infant; but after one year there are, very commonly, the essential marks of them. Allow me to bring before you those pictures of *habitus* which I have taken from nature, and found suitable to the purposes of practice:—

1. The *normal habitus* needs not, I think, to be described. There is a regularity in the whole frame, and a harmonious proportion between all its single parts.

2. *Nervous habitus.*—A delicate, slender, but proportional complexion, with a fine forehead; during the first years of life, frequently a large skull, but no notable abnormity in the ossification; very commonly light hair, thick and fine; skin delicate, with the veins transparent, in particular on the temples; much sensibility and vivacity, and eminent intellectual gift. It is more expressed and frequent in females, with a disposition to convulsions and spasms; eclampsy frequent about the first dentition, and fatal without inflammatory changes of the brain; between the eighth and the twelfth year frequently attacked by chorea. If this habit is strongly expressed, cold lotions of the head and the spine are recommendable.

3. *Scrofulo-phthisic.*—Much like the former, but rather a small chest and prominent scapulæ; long and thick eyelashes. We might call it also scrofulo-nervous *habitus*. About the dentition much subject to pure nervous convulsions, less to hydrocephalus; this latter affection more frequent above the third year. Between the fourth and twelfth year much disposed to catarrhal affections, in particular of the bronchi and the eyes, with slight superficial erosions on the sclerotic and cornea, with a little swelling of the glandulæ meibomiæ. About puberty, frequent tubercolosis in the texture of the lungs. It is difficult to counteract this disposition by hygiènic means. Gradual strengthening of the body by exercise promises most.

4. *Scrofulo-impetiginous.*—Large skull, sometimes angular; face of different proportions, if very small in comparison to the skull, it is the worse; long and thick eyelashes, thick lips, abdomen bloated, and flabby legs; retarded ossification and locomotive power; hair of different colors, seldom very dense; coarse skin; voracity for farinaceous substances; frequently nocturnal head sweats. Disposed to eczema, impetigo, and achor on face and head; to glandular tuberculosis, to hypertrophy of the brain, to hydrocephalus, to caries of the joints and vertebræ. The greatest danger and mortality between the first and third year. Hygiène:—The most convenient articles of food are animal flesh and greens; no farinaceous things, much open air and exercise. Luke-warm salt baths, and cold lotions, with friction after it. Iodine is the most powerful remedy against the scrofulo-impetiginous dyscracy.

5. *Scrofulo-rachitic.*—Large skull, with too protuberant frontal tuberosities, proportions of the face different, frequently large and bloated, very long and thick eyelashes, a semicircular furrow beneath the lower eyelids; dense hair, commonly dark and growing even over the upper part of the front; a very visible down over the whole surface, in particular on the front, the outside of the arms and legs; the articulations in a somewhat enlarged state. Thick lips, bloated abdomen, and thin flabby extremities, coarse skin; voracity of farinaceous substances; much retarded ossification and locomotive power; pigeon breast, and laterally excavated narrowed chest; disposition to rickets. Hygiène: animal food, some little of a good wine, dry open air, cold spiritous lotions, and frictions of the whole body. No warm baths.

6. *Bilious habit.*—Seldom clearly recognizable, and even seldom developed in the first years of life; proportional development of the body, with the exception of some prevalence of the hypochondria; dark hair; the colour of the skin rather impure, sometimes with dark red flushed cheeks; disposition to acute diseases and bilious affections. Vegetable food, in particular greens; luke warm baths.

7. *Sanguine* not distinguishable in little children from the regular habit. In general healthy and cheerful children, always in good spirits, with the same vivacity which we have pointed out as one of the properties of

the nervous habit, but without that excessive degree of sensibility which characterizes the latter, may be regarded as in possession of the sanguine habitus.

Besides these portraits of habitus and dispositions, we meet with infinite gradations of mixtures of them.

If we compare the nervous with the scrofulo-phthisical habit, as described, we shall find the most obvious the mixture of both in one individual; taken physically, these habituses, as they present themselves before our eyes, and according to great many analogies which we find between both, we must recognize an intimate relation between them. I am not able nor willing to trace tubercles of the lungs to the superabundant nervosity as a source; I state only the fact, as I observed it very frequently.

The same relation and affinity we find between that habitus which I described as the scrofulo-impetiginous and the rachitic. There is a condition of the body, very frequent between the 9th and the 18th month, with a large skull, large abdomen, flabbiness and weakness of the limbs, which either develops fully into rickets, or into impetiginous scrofula.

The *position* of the body of the child, in bed as well as in the arms of the nurse, is frequently indicative of the quality or local seat of disease. It is a long time since this was observed and regarded as a matter of significance by clever practitioners. I limit myself to mentioning the dorsal position as almost exclusive in transudations in the head, in typhus, in acute carditis and pericarditis, and acute peritonitis or enteritis. Dorsal, but with more or less lateral inclination, in acute affections of one of the lungs; we observe even, that in acute lobar hepatization the child keeps almost constantly the position on the affected side, and is prevented from laying on the healthy side by cough and dyspnœa. The position of pleurisy, however, is inconstant. I observed frequently the lateral position on that side which is opposite the one affected. In large transudations, on the contrary, I observed frequently a dorsal position, or inclined, over the healthy side. The most unsteady position we find in gastric disorder, or chronic abdominal affections; in abdominal glandular disease they lay frequently on the belly.

There are some very significative positions. If we find a child in the dorsal position, the head hanging backwards, with opened mouth, the lower extremities flexed in the knee, and negligently thrown outwards, the hands, or one of them, touching the genital organs; we may suspect a transudation in the brain.

The *movements* of single parts, automatic or convulsive, or weakness, or pain in moving them, or impeded movement by pain or contracture of that part, should not escape our attention. In young infants severe fits of eclampsy commence frequently with slight convulsive movements of the muscles of the eyes, or of the cheeks and mouth, by which the infant seems to smile, and causes, by this appearance, pleasure to the mother, who soon will be subjected to a dreadful deception. In children from seven years upwards, chorea commences, with slight irregular movements of the head and the extremities, generally attributed in that stage of the disease merely to bad habit.

Temper, habitudes, and inclination.—The temper of the little patient must be valued, in any circumstance that we find the child fretful, or much inclined to cry. We mentioned, however, already, that the biliary habit is very seldom developed in infancy and early childhood, at least I regard this case as a rare exception before the eighteenth month. Consequently, if a little child is fretful, and cries frequently, we must closely inquire into the cause.

The habitudes of children depend much upon the method of their usual management, with which we must never neglect to make ourselves acquainted. Sudden changes in the regular habitudes, pleasures, or affections of the child, or some constant salient abnormities in habitudes and affections, enable us sometimes to conclude upon the commencement or presence of certain affections.

I mentioned already, and bring it once more under your consideration, that none of all those objective symptoms of which I have given a short review, taken alone, has a constant and absolutely inherent diagnostical signification. I find it very useful to make that sort of analysis of single phenomena, but the art of diagnosis accomplishes its difficult task by clever comparison and synthetical composition, after the premised analysis of them.

CASE OF

POPLITEAL ANEURISM,

CURED BY PRESSURE UPON THE FEMORAL ARTERY.

By G. M. HUMPHRY, Esq.,

SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Read at the Branch Meeting of the Association, at Ely, June 17, 1851.

William Mitchell, aged 24, from Wisbeach, admitted into Addenbrooke's Hospital, August 1st, 1849: in ill health, with anxious pained expression, sallow complexion, pulse 104.

The ham and lower-third of the inside of the right thigh occupied by a firm swelling, giving a circular measurement of eighteen inches and a half; the left limb, in a corresponding situation, giving only thirteen inches and a half. The swelling was most prominent a little above the internal condyle, and at the middle of the ham, uniformly firm, but communicating an indistinct sense of fluctuation. Its outline could not be clearly ascertained in consequence of an œdematous condition of the subcutaneous tissues. The integuments were natural, with the exception of a faint blush in places, and a few white starry spots, like cicatrices, which he said had appeared within the last few days. There was effusion into the knee-joint, raising the patella and still further distorting the limb. The part was exceedingly tender, and he suffered great pain in

the swelling, and agonizing pains shooting down the limb; the skin of the leg and foot feeling, to use his expression, as if it were being burnt in a fire. He was restless, incessantly turning about to find a more easy position. The limb below the knee was œdematous, rather cold, and devoid of sensation below the middle of the leg; he could not move the foot or toes. The femoral artery could be traced to the lower-third of the thigh, where the swelling began. No pulsation could be felt in the anterior or posterior tibial arteries. No pulsation whatever could be felt in any part of the swelling, nor was his severe pain in the slighest degree relieved, or the size of the swelling diminished by pressure upon the artery at the groin, though it was continued for several minutes, so as to prevent the passage of blood. A distinct bruit was audible over the tumour; and there was also a bruit, synchronous with the first sound of the heart, heard over the commencement of the aorta.

He was a sailor. Seventeen weeks before his admission he had been compelled to leave his ship in consequence of an attack of rheumatic fever, which continued severe for about five weeks. During the whole of that time he suffered a good deal of pain about the right knee, more particularly in the neighbourhood of the inner condyle of the femur. When the pain subsided in other parts it continued unabated in the knee. About this time he first observed the swelling, which began on the inside of the ham; it increased quickly and was attended with distinct beating, which he could see and could feel with his fingers. He was very clear upon this point, and said that several surgeons had examined the swelling and had perceived the beating within the last few days. It seemed probable, therefore, that the cessation of the pulsation was dependent upon some inflammatory changes in the aneurism or the surrounding parts caused by the journey to Cambridge.

He suffered acute pain all night in spite of fomentations and opium, and on the 2nd was still in great agony. The œdema had rather increased. No bruit or pulsation could be perceived in the swelling. Twelve leeches and fomentation applied, and a grain of morphia given at night.

3rd.—Less pain; swelling rather less tense; the bruit had returned; still no pulsation.

4th.—A further diminution of pain. The swelling softer and fluctuation more evident. Pulsation could now be distinctly seen and felt; but it was limited to the course of the popliteal artery, not being perceptible in any other part of the swelling.

7th.—The pulsation of the whole tumour being to-day quite decided and the bruit audible, there remained no longer any doubt as to the nature of the case; so we determined at once to commence treatment by pressure. The arch tourniquet (Santorini's) was applied a little above the middle of the thigh, and the common torniquet at the groin; the latter being retained in place by a strap round the pelvis and another round the upper part of the thigh. Great pains were taken to stop completely the pulsation in the artery, and in the tumour, and it required considerable pressure to do this. However, the tourniquets being used alternately, the object was attained continuously for several hours without much inconvenience to the patient; and after fifteen hours of effective treatment, the pulsation in the tumour had entirely ceased. Constant pressure was kept up for two days longer; afterwards the tourniquets were applied only at intervals. In three or four days, when the swelling had begun to diminish, he was greatly troubled with pains in the feet and toes. This was probably dependent on some change going on in the nerve consequent on the partial remission of pressure upon it as the aneurism decreased in size, for on August 30th the pain had nearly ceased. Still there was no sensation below the middle of the leg, and no power to move the foot and toes.

September 4th.—No pulsation or bruit. The size of the tumour decreases slowly. The movements of the knee are much more free

October 4th.—Has for sometime moved about the ward on crutches, swinging the right leg. Moves the knee boldly though not quite freely. The size of the swelling diminishes very slowly, the circular measurement being still 17 inches. It is soft and indistinctly fluctuating. Sensation exists over a greater space than it did, but he cannot move the foot and toes, which remain swollen. The femoral artery may be traced to the lower-third of the thigh. There is no pulsation perceptible in the tumour or in the tibial arteries. The œdema of the foot might prevent its being felt in the latter. Returned to his home.

In the course of the following winter he was again in the hospital for several weeks, on account of the paralytic condition of the foot, which continued, although the aneurismal tumour was smaller and soft, and pulsation had entirely ceased. Electricity was used, with some benefit, and he again went home. Some months afterwards he was attacked with inflammation of the chest, and died. Mr. Burnam, who attended him at Wisbeach, wrote me word that he had recovered the use of the limb, and that the swelling in the ham had almost disappeared before his death.

In this case the origin of the disease in the popliteal artery was clearly traceable to rheumatism. It is very seldom that such a cause can be assigned for the commencement of aneurisms in the extremities; the disease being usually attributed to an injury, a sprain, or to free movement of the part. Even in the thorax the diseases of the arterial coats that give rise to aneurism, are more generally dependent upon age or intemperance than rheumatism.

The extent to which the characteristic symptoms of aneurism were, on the patient's admission, masked by a tense inflammatory condition of the surrounding tissues deserves particular attention. At one time both pulsation and bruit were entirely absent, and pressure upon the femoral artery failed to produce any alteration in the swelling; indeed the swelling then resembled an abscess more than an aneurism, and it is certainly no wonder that mistakes in diagnosis should, under similar circumstances, have, in more than one case, led to

serious mistakes in treatment. As the inflammation and tension diminished, first the bruit and then the pulsation returned.

The cure by pressure upon the artery above the aneurism was effected in a shorter space of time than in any other case of which I have seen an account; all pulsation in the tumour having ceased fifteen hours after the treatment was commenced, and it never returned. A case is related in Dr. Bellingham's "Observations on Aneurism," treated at the Royal Military Infirmary, Dublin, in which pulsation ceased after ten hours of compression, maintained by two instruments alternately relaxed, (the pressure upon the artery being sufficient to check completely the pulsation in the tumour,) and it did not return. In this case, however, it is to be observed, that pressure had previously been applied to the artery in the groin by a weight, and had, it was supposed, caused some deposition of fibrin in the aneurismal sac. Not long ago a case was related at the Medico-Chirurgical Society, by Dr. Bellingham, in which the pulsation had ceased twenty-three hours after compression had been commenced. In the greater number of cases of which reports have been published, weeks, and even months, of patient endurance and constant attention have been required to bring about a successful issue. Indeed the great, perhaps the only, valid objection to the treatment of aneurisms by compression of the artery above the tumour, is founded on the tediousness of the process, and the pain to which the patient is subjected by the long-continued pressure of the tourniquet. In all other respects there can, I think, be no question that preference is due to the treatment by compression in comparison with that by ligature. Its general efficacy has now been proved in a sufficient number of cases. Of thirty-six cases treated in this way, in Dublin, we are informed that twenty-nine have been cured. If properly conducted, the procedure is almost entirely devoid of danger, either to the limb or to the patient; and, if it fails to effect a cure, the patient has not been placed in a more unfavourable position for the treatment by ligature. In cases where it has been necessary to operate under such circumstances, or where an opportunity has been afforded of dissecting the parts after compression, it has been found, with one or two exceptions, that neither the artery nor its investing cellular tissue, have been subjected to any material alteration at the part pressed upon, so as to increase the difficulty of the operation, or to modify its results.*

From the history of cases, and the dissections that have been made, it appears almost certain that the cure of aneurism, whether the means used be compression or ligature, takes place in much the same manner, viz., by the formation of coagulum in the cavity, and the subsequent absorption of that coagulum and contraction of the sac. The formation of the coagulum appears, in most instances, to be the primary and essential part of the process, and the treatment is likely to be effectual and speedy, in proportion to the degree in which it favours the coagulation of the blood in the sac, by placing it at rest. It is by no means necessary that the artery should be obliterated at any part of its course. True, it commonly is obliterated in the vicinity of the aneurism; but in all the instances of dissection after cure by compression that I have met with, the artery has remained pervious above the aneurism; and even where ligature has been employed, it has not unfrequently remained pervious between the ligature and the aneurism. It is not even necessary that the circulation through the artery should be completely arrested, a mere retardation of the current of blood being sufficient to permit the deposition of fibrin in the sac, which is already favoured by inequalities in the surface of the sac and other causes. Nevertheless it must be borne in mind, that the more completely the current is suspended, the more quickly will coagulation take place in the sac, and the more speedy, as well as more certain, will be the cure. I do not think that this point has been sufficiently attended to in the treatment of aneurism by compression. So much has been said about its being requisite only to moderate the force of the arterial stream, that surgeons have been content in many cases with applying very slight pressure, have thus prolonged the treatment over an unnecessary period, and have sometimes failed to produce the desired result altogether. This at least has, I believe, been the case in most instances where so much time has been required to effect a cure; or, what amounts to the same thing, the instruments have been clumsy and insufficient, or the patient intolerant of pain.* Surely more numerous and more speedy cures would be obtained, and the new treatment would lose some of the reproach which now attaches to it, if the attempt were made in each case to carry it out more vigorously and effectively. In doing this, great care and great attention is required. Two, or even three, tourniquets should be used, so as to distribute the pressure over a greater surface, and to permit of a variation in the points at which it is applied. The instruments should be well adapted, and the surgeon should visit the patient frequently to adjust the apparatus, and regulate the pressure. If it can be done, without giving much pain, the pressure upon the artery should be maintained with such force as completely to stop the pulsation in the tumour; and great pains

* In a recent discussion at the Medico-Chirurgical Society, Mr. Cock is reported to have said, that he "had experienced some difficulty in applying the ligature after compression had been used, in one case, from thickening and absorbent inflammation over the sheath." I do not find any mention of this difficulty having been encountered in other cases of the same kind. Mr. Hewett has, in two instances, made most careful dissection, without discovering any thickening in the sheath or cellular tissue surrounding the vessels. In one case dissected by Dr. Bellingham, where pressure had been applied for twenty days, when the patient died suddenly from disease of heart, there was "some slight thickening of the cellular tissue around the vessel, at the situation where the pressure had been made, but no alteration whatever in the vessel itself." In two other cases there was nothing to indicate the points at which compression had been made; and in a fourth, the artery above and below the aneurismal sac is said to have been healthy.

* Doubtless, as Mr. Paget suggests in his remarks upon a case lately published in the *Medical Gazette*, the particular form of aneurism, whether it be "saccular" or "tubular," must have great influence on the facility with which coagulation of its contents will be brought about; the uniformity of the dilatation in tubular aneurism being very unfavourable to such a process. But this is not sufficient to explain the lengthy periods consumed in the treatment of popliteal aneurism by compression in so many cases, because the "tubular" form of aneurism is very rare in the ham.

should be taken to effect this. If that cannot be done, we should endeavour to effect this, as nearly as possible, by maintaining as much pressure as the patient is able to bear. In a great number of the recorded cases no mention is made of the amount of pressure employed; but so far as I have been able to gather, the cures have been far the most expeditious, and on the whole the least painful, where the surgeon has made it his object not merely to *moderate*, but to *stop* the pulsation of the aneurism.

CASE OF

RUPTURE OE THE BLADDER FROM EXTERNAL PRESSURE.

By Dr. TOMKINS, Yeovil.

During the spring of 1847, when the railway works were in progress near this town, an excavator, in undermining some earth in a deep cutting, was thrown from a height of more than twenty feet; the ladder on which he was standing was knocked from under him by the sudden fall of an almost solid portion of earth, weighing several tons. The man fell on his back, and the pickaxe with which he was working, together with the ladder, were thrown several feet behind him. The main bulk of earth descended on his abdomen, and it required the united efforts of nine or ten men to lift it from his body. He was conveyed home, and visited by my son, Mr. W. F. Tomkins, surgeon, who found the abdominal integuments much contused, and an extensive lacerated wound in the perineum, through which three fingers could be passed with ease, and which enabled him at once to discover that the bladder was ruptured.

My son sent for me to visit the case with him; and on my arrival I found the man almost pulseless. There was considerable hæmorrhage from the wound, which was three or four inches in extent, laying open the posterior portion of the urethra. I passed my finger through the wound, and found the bladder extensively ruptured, and at the same time introduced a catheter by the urethra, and brought it readily through the rent in the perineum. When reaction took place, the patient suffered most intolerable pain, accompanied with sickness and vomiting, for which a grain of opium was given every hour or two, with the best effect.

It is unnecessary to detail the symptoms and treatment of the case from day to day. Considerable sloughing of the integument of the abdomen took place. Fomentations and poultices were applied; the bowels were kept open by the aid of injections and castor oil; his strength was kept up; and opium given freely to soothe his pain, to the extent of from eight to sixteen grains a day. The wound soon began to assume a healthy aspect. A catheter was passed from day to day, and occasionally kept in the bladder a few hours at a time. At the expiration of two months the wound had healed, leaving the course of the urethra rather tortuous; but at the end of another month, when the man left the town, the bladder was so far restored as to enable him to retain from eight to twelve ounces of urine.

Remarks.—This is an important case in surgery, proving that rupture of the bladder is not, as has been supposed, *necessarily a fatal injury*, and points out to us the necessity, in the event of such an accident, of our immediately making an external opening to give vent to the urine, which otherwise must be retained in the peritoneal cavity, and occasion death.

By such an operation we merely place a patient in the same position that he would be in after the lateral operation for stone with the gorget; for the wound in the perineum and urethra was as clean as if it had been cut with a scalpel; and here comes the question as to how the wound was produced. It is certain it was not from the entrance of any extraneous substance from without, for the man had on a pair of new corduroy trousers, suspended by his braces, and there was not the slightest rent about them. It is, therefore, evident that the weight and pressure of the earth compressed the bladder so completely within the pelvis that the urine was sent forward with such force as to tear the urethra and perineum in the manner described; and this tends to point out to us the utter impossibility of deciding, in many cases, the precise mode in which wounds are inflicted, or the weapons or missiles by which they have been caused.

CASE OF

RUPTURE OF THE FALLOPIAN TUBE.

By CALEB WHITTON, M.D., Llangollen.

During the course of this month Mr. Cotton, surgeon, Northampton, was requested to see a poor woman, aged 26, the wife of a shoemaker. She complained of severe pain in the abdomen, some vomiting, and had rather a feeble pulse. This was in the afternoon, and she had been taken ill about mid-day. Some purgative pills with opium were prescribed. In the evening he asked me to see her with him, as I was staying a few days in Northampton. We found the pain somewhat less, slightly increased by pressure; pulse extremely feeble, and the patient apparently sinking; we both considered there was some serious lesion of the abdominal viscera, but of what nature we could not pretend to determine. She considered herself three months advanced in pregnancy. Early on the following morning she died. A *post-mortem* examination discovered the effusion of about three pints of blood into the abdominal cavity; a large ulcerated rupture in the left fallopian tube, about its middle; a fœtus of about two months amongst the extravasated blood, and two small hydatids on the left ovary. She had been in her usual health in the morning, and whilst out had stumbled over a stone.

Llangollen, September 30, 1851.

OBSERVATIONS

ON NITRATE OF SILVER STAINS OF THE CONJUNCTIVA.

CASE OF ABSOLUTE BLACKNESS.

By JAMES VOSE SOLOMON, Esq., M.R.C.S.,

Surgeon to the Birmingham Eye Infirmary.

The application of a solution of nitrate of silver, if long and injudiciously applied to the conjunctiva of the eye, produces a discolouration which is indelible. The sclerotic conjunctiva becomes of a dusky brown, or of an olive colour; the palpebral linings, more particularly of the lower lid, assume a brownish or livid hue, or, as will be presently shown, may become black; the sulcus between the inferior lid and globe is more deeply dyed than the other parts. In the majority of cases which have come under my notice, the conjunctiva of the superior lid retains its natural colour. In a few rare instances the salt becomes incorporated with ulcers of the cornea, forms a subchloride of silver, and perpetuates one or more black lines in their cicatrices.

A still more uncommon, and I believe hitherto unrecorded change of colour, consists in absolute blackness of the conjunctiva, an instance of which, the only one that has ever come under my notice, is probably of sufficient interest for publication in the *Journal*.

Case.—A young woman, aged 29, came from a small town in Radnorshire to consult me for a dimness of vision. Both cornea were extensively covered by opacities, which were irregularly streaked with black lines. The caruncula lachrymalis and tarsal borders were of a jet black colour, giving the appearance, at a cursory glance, of soot or dirt settled on those parts. The palpebral conjunctiva was smooth, and in colour not quite so black as the margins; the sclerotic conjunctiva was of a deep olive colour. I found on inquiry, that she had at one time suffered from strumous ophthalmia, for the cure of which a strong ointment and some drops had been prescribed and freely used; these applications were continued for three or four months.

The black streaks which traversed the opacities of the cornea and the olive sclerotic conjunctiva, decisively indicated the nature of the other discolorations. There is a much greater susceptibility to these stains in some individuals than in others. They are more common to adults than children; possibly because ophthalmic disease among the latter is for the most part either of the strumous or purulent kind, in both of which the surface of the eye and its appendages are continually bathed in secretion.

If we excise a portion of discoloured sclerotic conjunctiva, a white cicatrix is formed, indicating that the fibrous membrane retains its natural colour.

As we are at present unacquainted with any means for removing the stains under consideration, our obvious duty is to prevent their occurrence by vigilant attention and care, which may be accomplished by prescribing the preparations of nitrate of silver, in short and intermitting courses, and by frequently noting the condition of the lining membrane of the inferior palbebra. In public ophthalmic practice, it would be well if the solution were not dispensed in larger quantities than two drachms at one time.

Since writing the above, a man, 60 years of age, who has been all his life a martyr to rheumatism, has become my patient at the Eye Infirmary. The right globe is collapsed; the left eye retains some vision, it has been repeatedly inflamed; the iris is of a dull leaden colour, and convex towards the cornea; the pupil is puckered, adherent to the lens, and filled within a third of its area by opaque lymph (artesia iridis imperfecta); near the centre of the cornea is a leucoma.

Fifteen or eighteen months ago, he for the first time consulted a surgeon, who prescribed caustic drops, which he has ever since applied. The conjunctiva of the inferior palbebral sinus is of a greenish black colour. The inner surface of the surperior lid has lost somewhat of its natural polish; a few black dots assume an aborescent shape near the superior punctum; a light brown and well-defined narrow stripe extends along the concave aspect of its tarsal cartilage.

I have cited this case to show the impropriety of allowing patients to use the preparations of lunar caustic *ad libitum*; and as an interesting example of how well the superior lid escapes serious change of colour, even in the very worst and most neglected cases. It also illustrates the destructive character of uncontrolled rheumatic ophthalmia.

ON

MEDICAL DELUSIONS & CHARLATANIC PRACTICES.

By BENJAMIN W. RICHARDSON, Esq.,

Licentiate of the Faculty of Physicians and Surgeons, Glasg.

I. Homœopathy.

Of the thousand popular medical delusions, that have at various times been brought forward, there are few that have taken so firm a hold upon the public mind, as the one known under the name of homœopathy. This arises mainly from the fact, that the science of legitimate medicine, during the last century, has advanced so much, and the information of medical men has become so great, that the public generally are lost in attempting to follow the scientific physician; but being at the same time anxious not to feel ignorant, in a matter that so greatly concerns themselves, they are ready to turn their attention to any system which they think they can comprehend, however backward or however dangerous that system may be.

Now, the homœopathic system answers this purpose: it falls back upon the medical knowledge and the medical ideas of the people; it also makes use of plausible arguments, and works upon that powerful element of the human mind—the love of the marvellous.

In the days of the famous Greek physician, Alexander (Trallanius), there practised at Constantinople another physician, called Uranius, a man so far behind his scientific friends in information, that they justly laughed at him and treated him as a buffoon. This man went with the Ambassador Arebindus, to Persia, where, by artfully concealing his deficiencies and assuming the gravity of a philosopher, he so pleased Chosroes, the Persian King, that the Magi were assembled to consult with him on questions of natural philosophy. Uranius, though ignorant of these matters, by his *confidence*, supported his reputation, having this advantage over his adversaries, that if he knew little on the subject, those he disputed with knew much less; and the king was so charmed with him, that he pledged him at table, and declared, that of all the philosophers he had seen, (and the most famous had visited his court,) Uranius was the most acute and accomplished. "The reason," (for this admiration of the King) says the sensible old writer from whom the account is borrowed,* "is plain and natural, which is, that we have a great inclination to everything that resembles us, and an aversion to whatever is above us. It must be owned that Chosroes had all the qualifications necessary to form a great captain, but for what relates to learning, it must be confessed that he could attain to no greater height than what a scholar of Uranius could arrive at."

Now, the non-professional part of the public hold just the same relation to medical science as Chosroes did to natural philosophy. They may be great captains, learned in law, giants in theology, admirable historians or politicians, and skilled in other branches of learning; but of medical science they can know nothing without spending their whole lives in the study of its principles. Hence, to the public, the reasonings of a medical Uranius are logic itself; it seems to them that by comprehending these reasonings, they have attained suddenly to a perfect knowledge of what they before considered a mysteriously intricate science, and many of them prefer the new plan to all others, because it adapts itself to their capacity.

One can almost imagine that there exists a kind of balance in the world of knowledge, as in the world of nature. It would seem that men must progress, *en masse*, not in sections. This man represents a body of men, and has advanced too far, and if he continues to progress at his own rate, his comrades will not be able to follow him or appreciate the benefit of his services. The event is foreseen with the evil of it. So a clog is attached to the man. He is galled by it; as indeed, well he may be, for he knows he is acting rightly, and sees the clog to be in itself a very foolish thing—an idiot pulling at his skirts. But bear it he must; and the good will follow. His friends will in time march to their proper position; he will then be allowed to go on unimpeded, and will feel none the less safe, in not being too far ahead. Now, of all sciences, medicine is the one most commonly clogged from this cause; the people are very much concerned by it, and they will have it at something like an understandable distance from them, so that if it dares to advance beyond a certain limit, some visionary system springing up behind it is sure to meet with great patronage. In this manner a Morison rises, and assuming to himself the character of a medical Saviour, mixes at random a powerfully dangerous nostrum, and holds it up for sale. The trick succeeds: Morison's pills are bought as fast as green peas in June; and the innocent babe at the breast has thrust down its throat a dose of medicine strong enough for a middle-aged elephant. But by-and-by this delusion goes the way of all fallacies; and now, by a strange exhibition in the rule of contrary, there rises another fashionable system—the homœopathic, by listening to the doctrines of which, full grown persons are induced to swallow a dose of medicine so small, that the same dose suspended in the throat of a gnat, would show a proportion similar to a pin's head suspended in the dome of St. Pauls.

The object then, of these papers, is to show, in simple language, and by an appeal to common sense, the absurdity of this last variety of popular medical delusion —homœopathy.

For this purpose, several of the most prominent homœopathic assumptions are first noted down and then discussed. The assumptions are all to be found in the numerous books put forth by homœopathic writers.

Concerning the sincerity of homœopathic practitioners no mention will be found in the following papers. They are written against the system, not the men. Neither does it form any part of their object to recal such practitioners into the pale of legitimate medicine, because it is believed that all who *heartily* practise homœopathy as a profession, are past all recal, even though a Plato should reason; while for others, if others there be, who practise the system for lucre's sake only, believing it not, these stand at so low a figure in the moral barometer, that the dignity of any man would be sullied even by thinking of them. Finally, while the attention of the public is respectfully directed to what follows, it is deeply regretted that in this enlightened day, any writer should have the occasion allowed him of fighting with a shadow, and that too, in defence of science, reason, and truth.

The Homœopathic Assumptions.

The assumptions of homœopaths about to be considered, are six in number; many more might be added, it is true, but these will be found to embody all the leading doctrines of the Hahnemannic system, together with the most popular arguments used by homœopathic writers. The assumptions are:—

1st. That diseases arise from two sets of agents, viz., natural agents and medicinal. Thus, the disease ague, as it arises from marsh miasmata, is a natural disease. Salivation, as it arises from the effects of mercury, is a medicinal disease. And that this distinction of diseases was first made by Hahnemann, the founder of homœopathy.

2nd. That three plans are followed by medical men in the application of medicines for the treatment of diseases:—

* Dr. Friend's History of Physic.—p. 130.

(*a.*) *The antipathic*, in which the axiom *contraria, contrariis curantur*, is acted upon, which translated implies, that in disease contraries are cured by contraries. Thus a patient suffers from constipation, and a medicine is given which, in health, would produce the opposite of constipation—relaxation.

(*b.*) *The allopathic*, in which *one disease is tried to be cured by setting up another*. Thus, a man suffers from what is called determination of blood to the head, and a seton is inserted into the nape of the neck; the allopath, says the homœopathists, hoping by this means to set up a new disease in the neck, and so to cure that in the head.

(*c.*) *The homœopathic*, in which the axiom *similia similibus curantur* is followed, meaning, that similar diseases are cured by similar, which axiom is combined with a second, *that no two similar diseases can exist in a state of intensity in the same body, at the same time*. Therefore, if the lungs suffer from inflammation, a remedy is given which would, in health, produce inflammation of the lungs. Or, if the nose suffer from bleeding, a remedy is applied that in health would produce such bleeding, (a smart tap on the organ for instance;) or the bowels are constipated, and a remedy is given that in health would produce constipation.

3rd. That Hahnemann, the founder of homœopathy, and his followers, have, by experiments on themselves and others in a state of health, discovered that for every natural disease a similar disease is capable of being excited by a medicinal agent. Thus, Peruvian bark is said to possess the power of producing a disease similar to ague, nux vomica of producing a kind of palsy, and so on; therefore, on the strength of the last assumption, these experimentalists have discovered the means of cure for the same diseases.

4th. That in prescribing medicine, the more minute the dose administered the better, and the more safely will it act, so that medicines may be divided into doses consisting of the millionth, trillionth, or decillionth part of a grain, and yet retain their efficacy.

5th. That to homœopathists is due the credit of first calling particular attention to diet, cleanliness, and exercise, as curative means in the treatment of various diseases.

6th. That the practice of homœopathy is safe and effectual; that it places medicine amongst the fixed sciences; and that it is destined to become the practice of all truly scientific men.

The Correctness of the Assumptions.

The first assumption treats of diseases as arising from natural or morbific, and from medicinal causes.

Of the correctness of the doctrine, that certain morbific agents are capable of producing certain diseases, no doubt can be entertained. Marsh miasm produces ague; scarlet fever contagion produces scarlet fever, &c. Nor can it at all be doubted, that medicines carried to an excess in their administration, produce sometimes a powerful effect on the body, a disease in fact; therefore the division of diseases into natural and medicinal is a proper one. But let no one conclude that homœopathists were the first to make the division here spoken of. The division has been known and used for nearly two thousand years. Thus Hippocrates, the father of medicine, who lived more than 400 years before the birth of Christ, spoke of the effects of impure states of the air as productive of disease, and also of the classes of symptoms, that is to say of the diseases induced by remedial agents, and in this he has been followed by all other writers; indeed the study of the diseases produced by medicinal agents was, without doubt, almost the first step made in medical science, and has ever held a distinct and important position. At the present day there is not a school of medicine existing that does not possess one teacher at least whose only office it is to give instructions on the natural causes of disease, and another teacher to give instructions on the effects or diseases that may be induced by medicinal agents.

This first homœopathic assumption, therefore, is utterly at variance with truth, in so far as it speaks of Hahnemann as being the first person who divided diseases into natural and medicinal, and of the followers of Hahnemann as being the only persons who use such a division.

Mortlake, Surrey.

[To be continued.]

ON THE PROGRESS OF PUBLIC HYGIÈNE AND SANITARY LEGISLATION IN ENGLAND,

AND THE ADVANTAGES TO BE DERIVED FROM THEIR FURTHER EXTENSION.*

By J. INGHAM IKIN, Esq.,

Fellow of the Royal College of Surgeons of England, and Lecturer on Anatomy and Physiology in the Leeds School of Medicine, etc.

Read before the Leeds Philosophical Society, March, 1851.

A recent enterprising proceeding, which will tend strongly to advance the cause of hygiène, as well as to benefit the public generally, is the "Inquiry of the Analytical Sanitary Commission," and the publication of its results in the *Lancet;* the Editor deserves our best thanks for such exertions. Their utility is already being felt in London and elsewhere. This Commission furnishes information as to the quality, composition, and adulteration of the various articles of food in common use, as well as that of the water; and it promises to examine wine, spirits, drugs, &c. It appears from these reports that ground coffee, so called, is very rarely, indeed, to be procured pure, and that it is adulterated not only with chicory but with many other substances not near so harmless; for chicory is adulterated with carrot, parsnip, mangel-wurzel, beans, roasted corn, biscuit powder, burnt sugar, red earth,

* Concluded from page 573.

oak bark tan, tan known as "croats," mahogany sawdust, baked horse's and bullock's liver, Hamburgh powder, Venetian red, &c.—a tolerable list sufficient to show what rascality is committed by some men, though calling themselves honest tradesmen.* With regard to sugar, its impurities and adulterations are equally startling. The "Acarus Sacchari," or sugar mite, abounds in the low-priced impure, moist, brown sugar, so no wonder the grocer's itch existing. In these sugars, also are found fungi sporules, starch, wood lime, lead and iron, stone sand or grit. Flour, potato-starch, and gum, are also used to adulterate sugar, but these are comparatively harmless. Lump sugar is recommended to be much more generally used, as being comparatively little exposed to these impurities and adulterations. The flour in London is found to be very pure and genuine; occasionally we have known cases of adulteration. In this town such has been the case to a somewhat large extent, but exposure ensued, and it is to be hoped the crime and fraud of adulterating flour is now rare. Chalk, bone-dust, plaster of Paris, and white clay, have been found in flour. The act of mixing by the miller is perhaps justifiable, I mean only that of mixing different qualities of the same grain; but meal is constantly adulterated with barley-meal. Bread, as is well known, often gets adulterated; and agents are employed to render it light, and of a good colour. Such agents should not be allowed, they injure the bread, and are not wholesome. The substances employed are—alum, sulphate of copper, (of course, in minute quantities, but sufficient to affect the health, especially of the delicate and young;) and the great majority of persons in the country accustomed to eat home-made bread, cannot take baker's bread, or London bread, without some annoying, if not dangerous symptoms. Rice-flour, boiled and mashed potatoes, are also found mixed with bread. Unsound flour, I need not add, should be avoided as much as possible; the flour mite soon makes its appearance when the sample is unsound; and diseases are apt to attack, to a formidable extent, the cereals, especially in wet and unfavourable harvests. "Bunt, smut, rust, mildew, ear-cockle, wheat-midge, are well known to the corn grower.

With regard to mustard, it is constantly found to be adulterated with radish-seed, rape-seed, wheaten flour, turmeric powder, and capsicum pepper; in fact, like arrowroot, it is very rarely to be procured pure, genuine Maranta arrowroot being scarcely ever sold. Pepper is adulterated with linseed, mustard-seed, wheat flour, pea flour, sago meal, pepper dust, husks and factitious pepper berries. Cocoa is constantly mixed and adulterated, not only with sugar and starch, but with other matters of an injurious nature. The farinaceous foods—ervalenta, revalenta Arabica, &c.—are spurious compounds, and the health of invalids has been often rendered much worse by taking them they mainly consist of lentil powder, resembling in colour, structure, and taste, the pea-meal, and, like both peas and beans, contain a large amount of nitrogenized matter, in the form of legumine. When lentils are taken as an article of diet, they are found indigestible, often occasioning distension and flatulency.

The profit derived from these farinaceous foods, such as Dr. Barry's Revalenta, &c., is enormous, the cost of the ingredients in a packet of 2s. 9d. would not amount to 6d. In this manner the inquiry of the Analytical Commission is now proceeding, and is likely to be always attended with most useful practical effects, by the exposure of the frauds to which the purchasers of articles like the above are subject.

It is to be hoped the whole class of foods and drinks will be investigated in the same accurate manner. The effect will be, it is to be hoped, that such adulterations will become much more rare, and that our food will be rendered more wholesome. All honest tradesmen dealing in genuine articles, should unite to expose and prevent the fraudulent dealer, then the public would have no excuse (with such facts proving the deception and roguery,) for encouraging cheap shops, falsely so called, but would be content, and prefer to pay a remunerative price for a genuine article.

A recent hygiènic measure of some importance, and one that the fearful extension of the crime of secret poisoning had called for, is the Act of Parliament regulating the sale of arsenic. The main provisions of this bill are as follows:—On every sale of arsenic the particulars of the sale are to be entered by the seller. No person shall sell less than ten pounds weight of arsenic

* *Tea and its adulterations.*—The *Lancet*, in three of its late numbers, has devoted a portion of its space to an exposure of the adulterations to which green tea is subjected before it reaches the hands, or rather the tea-pots of the consumer, a topic, it is to be feared, on which the "greenness" of the public is in proportion to its want of precise facts and information. The disclosures made by the "sanitary commission" of the Journal will be anything but gratifying to those who prefer "hyson," "young hyson," and "gunpowder," to congou or souchong; for while the principal black teas are declared to arrive in this country in a genuine state, every sample of green tea subjected to the microscopical test was found to be adulterated—that is to say, glazed with colouring matters of different kinds, which are employed to give a "facing" to the tea, and consist in general of Prussian blue, turmeric powder, and China clay. Not the least curious conclusion arrived at by the commission is, that in this country there is really no such thing as green tea—that is, one which possesses the natural green hue considered to characterise that kind of tea, that colour being invariably artificially produced by the materials above mentioned. Out of thirty samples to which chemical and microscopical tests were applied, not one was found possessed of the natural green colour; whereas, out of several samples of Assam teas, of British and Dutch growth and manufacture, and unquestionably genuine and entirely free from any "facing" whatever, the teas were of a dull yellowish colour, without the slightest tinge of green—resembling, in fact, the leaves of the adulterated samples of green tea imported from China, when deprived of the colouring so much patronised and admired. We are further informed that the British fabricators of spurious tea are but little behind them in the manufacture of imitation green tea, which they prepare from exhausted tea leaves, or from any other leaves which may be picked up by the hedge side, or in the wood, faced with ingredients of a still more poisonous description than are used by the Chinese themselves, the home adulterators thus contriving to "better the instruction" derived from the example of the foreign manufacturer. Directing their attention next from green tea as imported, to the same article as commonly sold, the commission state that of 20 samples purchased of various tea dealers in different parts of the metropolis, all were found to be adulterated. Whether any genuine green tea exists in China is held to admit of some doubt; but there is none at all as to the artificial colouring of all that is imported into this country, and consequently of all that is sold. We speak now of the respectable dealers, for it appears that those of the unscrupulous class are in the habit of mixing what is termed "lie tea" (an article most fitly named) with the choice "gunpowder" they retail to the public, and which is thus made to undergo a further deterioration after leaving the honest hands of the Chinese. The "lie tea" in question is a compound of sand, tea-dust, and clay, and is worth, exclusive of duty, only 6d. or 3d. a-pound, and, therefore, offers the temptation of large profits to those who are unprincipled enough to employ it for the adulteration of the superior kinds of tea.

at any one time, to any person who is unknown to the person selling, unless the sale be made in the presence of a witness known to the party selling, and to whom the purchaser is known, and who signs his name, together with his place of abode, to such entries, before the delivery of the arsenic to the purchaser; and no person shall sell less than ten pounds weight of arsenic to any person under age. Arsenic, before sold, to be mixed with soot or indigo, in the proportion of one ounce of soot or half an ounce of indigo to one pound of arsenic. The penalty of offending against the act is £20. It will not, however, interfere with the sale of Arsenic in medicine, under a medicinal prescription. The bill proposed for the regulation of the practice of chemists and druggists will, it is to be hoped, check the indiscriminate sale of laudanum, Prussic acid, &c. In order to extend and reap the benefits of the numerous recommendations contained in the Parliamentary and other publications referred to in this paper, and in order to promote the health and happiness of the community, and reduce the heavy mortality of our large towns, the public must not rest satisfied with calmly looking on or indifferently waiting for the adoption of measures from which they must derive the greatest benefit, but, they must co-operate with their advisers, and be willing to pay for such measures, as in all cases prevention is better than cure. Prudent expenditure in the promotion of sanitary measures will never have to be regretted, for the good effects, if not immediate, will be permanent, and our large towns will, by degrees, become healthier, cleaner, and improved in moral condition as well; for we know, from the highest authority, how closely akin cleanliness and Godliness are to each other. To promote this improved condition, we must have pure air, plenty of light, (now, fortunately, to be had without paying for,) and this light we must not lose the benefit of, as we are apt to do, by the inroads of smoke and dirt upon our glass windows. Smoke must be consumed much more generally than it is at present, for the practicability of its consumption is now admitted. A good supply of water must be had at any price, and all the poorer classes of cottages should be supplied free of cost by the landlord. All streets, passages, courts, &c., should be furnished with pipes and taps, for the purpose of cleansing the pathways, and jets of gutta percha tubing employed for washing the fronts of houses and windows, &c. The dismal, dingy, dirty appearance of our streets and houses might thus be to some extent removed. Adequate drainage and sewerage for all towns, are of course amongst the first grand measures to be adopted, and these must be done before any other improvements can be effectual. Public baths should be more generally supported in different localities; public washhouses for the poor, are found in London to be very convenient and useful, as well, I believe, as profitable; they should be erected in all our large towns and populous places. As to public parks, gardens, walks, and promenades, we are a century behind our continental neighbours; they are beneficial not only to the health, but they conduce to good feeling and social intercourse as well; our rigid habits of domestic privacy amongst the middle classes are often carried into extreme, and really at times prove injurious to health and mental vigour. Public dinners tend to promote good feeling, and as a nation we have the credit of enjoying them, and there is no reason why the public promenade, or rooms for well-ordered public amusements, should not be much more frequently resorted to, and found connected with every city and town in the kingdom. Manly exercises, games and pastimes, and innocent amusements, should be more generally encouraged. Timid mothers should be taught that cricket and other healthy games are more beneficial than injurious, and that the boisterous plays and exercises of boys at our large schools are infinitely superior to what may be considered as the more refined amusments at home; and after all, it would be doubtful policy to supersede or shun the national sports of old England, though they may, and often do, directly or indirectly, lead to folly, intemperance and gambling, but they are not so *abused* by those who really seek to *enjoy* them for the sake of the sport itself; and because parties are foolish enough to *abuse* them, that is no reason why they should be totally avoided; the fine manly character of the British yeoman would soon disappear, if their amusements had always to be sought in towns or at some insipid watering place. On the subject of the education and recreation of the physical powers, I have read papers here and elsewhere on previous occasions. Public opinion is now more alive to the importance of this question, and we are now beginning to adopt several salutary regulations in this respect; the shortening of the hours of business in our offices, warehouses, shops, and mills, is a step in the right direction.

The free admission to public museums and their establishment at the public expense, and the opening of cheap reading-rooms and libraries will in the course of time become much more general throughout the country, and thus the inducements to frequent the haunts of vice and intemperance will be less. These institutions cannot exist long without producing their good effects, and accompanying them, we shall find the public taste rapidly improving, our streets, squares, and houses will be constructed in better taste, and with more uniformity and architectural beauty. Our public buildings will be of a superior class to what they are at present, the close unhealthy courts removed, our common lodging houses much improved in accordance with the views of Lord Shaftesbury's bill, which arose from the able report of Mr. Grainger, "On the present state of certain parts of the metropolis, and on the model lodging houses of London." According to his Lordship's statement in the House of Lords, "The operation of the bill would, in the first instance, be limited to boroughs and parishes not having less than a population of 10,000 persons; and it was provided that the Council of any borough might adopt the Act, the expense to be charged on the borough fund; that, on the requisition of ten ratepayers, churchwardens might convene a vestry to determine whether the Act should be adopted; but the resolutions were not to be

deemed carried unless two-thirds voted for them; that, when the Act was adopted, the vestry should appoint Commissioners for carrying the same into effect, and that the overseers should levy, as part of the poor-rate, such sums as the vestry should deem necessary; that vestries of two or more parishes might concur; that Town Councils and Commissioners might erect lodging-houses, or adapt buildings, or purchase existing houses; that if lodging-houses were considered unnecessary, or too expensive, they might be sold with the approval of the Treasury; that the Council and Commissioners might make bye-laws, subject to the approval of the Secretary of State. Then came a provision which was necessary to prevent abuse, and it was to the effect that no person receiving parochial relief should be a tenant of these lodging-houses, except the relief was given on account of accident or temporary illness. The bill was guarded in every respect against the probability of jobbing, and against its being converted into eleemosynary uses, which would entirely destroy the object in view. A too rapid and too general adoption of the bill was also guarded against; and it had this advantage—that if faulty it could not be widely spread, as one or two failures would utterly check its operation. The bill violated no principle, but merely enabled a locality to provide what a labouring man could not provide for himself. There were reasons why this undertaking should not be left to private speculators. First of all, they shrank very much from it, because it required a great deal more care and supervision than any private individual was inclined to bestow on it, and, moreover, private speculators had a tendency to have recourse to small, narrow, and confined houses; for there was no doubt that such houses, without having any arrangements for decency and comfort, gave a much larger profit than constructions on the plan such as he proposed, and such as were, in his opinion, indispensable for the comfort and decency of the population. In proof of the enormous profits yielded by very small houses, he mentioned an instance of a house belonging to a society with which he was connected, and which they now kept as a mere curiosity. That house, notwithstanding every means of comfort and decency were afforded in it, compared with other houses of the same size, returned thirty per cent. on the outlay. What, then, must be the profit made by those who, having a large number of these small houses, took from the inmates the same amount of rent without giving anything like the same accommodation as the society he belonged to? There were at present a vast number of schemes for the improvement of the working classes, and he felt assured that those classes would, if the opportunity was afforded them, also improve themselves. The concurrent testimony of all persons conversant with the habits of the people went to show that the improvement of their domiciliary condition reversed all those frightful pictures which he had felt it his duty to present to their Lordships. On this subject also he might bring to bear the testimony of foreign nations. He knew no one subject which had so much excited the interest of foreign nations as that of the erection and management of lodging-houses for the people. Their Lordships would be surprised to hear of the amount of correspondence which had proceeded from all parts of Europe—from Paris, Germany, Spain, Italy, and also from the United States—asking for plans. He could assure their Lordships that not a few of the foreigners who arrived here to see the Crystal Palace came to him desiring to be taken round to those establishments formed for the benefit of the working classes, and they expressed their opinion that nothing was more satisfactory or more full of promise for the wellbeing of this country than the efforts made for the advantage of the working people, more particularly in that particular direction to which he now called their Lordships' attention. The present really was a measure by which they would give to the working man that which he had a right to possess—a full and free opportunity for the development of his energies."

Prince Albert's model lodging-houses are models in their way, and we have now an establishment in Leeds of the kind provided at the expense of Mr. E. B. Dennison. I append a short account of Prince Albert's model house, erected by His Royal Highness near the Cavalry Barracks, Hyde Park:—"The subject is one of great importance, and a visit to the building, which is now completed, will be found very instructive. For some time past a lively interest has been taken in this matter by the most philanthropic men of the age, for both in town and country the sanitary defects of the dwellings of the poor were felt to be a reproach upon our civilization. There were obstacles, however, in the way which it was found extremely difficult to overcome. In the first place the question of expense presented itself. Cottages were erected very pretty to look at, and a vast improvement in their internal arrangements on the old forms of dwellings in use, but when they were completed it was found that the cost, as compared with the ordinary rates of wages, precluded the idea of their extensive adoption, and that as trade speculations they would not answer. Considerate landlords have, nevertheless, provided in many instances convenient and comfortable accommodation for their work-people, actuated by a lauable desire to see them comfortable; and the Society for Improving the Condition of the Labouring Classes has erected model lodging-houses in different parts of the metropolis, which, being constructed on a large scale, have returned a fair profit on the money invested in them. So far success has been achieved, but it was necessary to carry the experiments made much further before any permanent or extensive effect could be produced in the objects contemplated. It was requisite to show that at a cost, if not smaller certainly not larger than that at present incurred for building the very inadequate houses which workmen and their families inhabit, houses could be erected giving them the benefit of sanitary arrangements, and providing for their increased comfort, cleanliness, and domestic decency. The rate of wages in this country, whether in the rural or town districts, leaves but a small margin over, after the purchase of food and clothing, for rent and the other expenses

attached to it. This sets limits to the outlay in building labourers' tenements which cannot be transgressed, and the consequence has hitherto been that they have been compelled to live in abodes totally unfit for human habitation, and which have led to an immense amount of preventible mortality among them. Damp walls and floors did one part of the work of destruction, and overcrowded rooms, where cleanliness, decency, and comfort were impossible, the rest. At this stage in the sanitary movements it is superfluous to say more on these subjects, as their evil influences are admitted on all hands. The question remained,—How were they to be dealt with? how was the working man to be provided with a suitable home at a rent which his wages permitted him to pay? It was found that the inferior bricks of which his humble tenement was constructed held water like a sponge, and that from one of them as much as a pint of moisture could be extracted. He and his family, therefore, were constantly undergoing, night and day, a species of hydropathic treatment which doomed them to inhale damp air, wear damp clothes, sleep in damp beds, and suffer all the complicated miseries which arise from walls streaming with water, and absorbing the rain from without, and the heat of the fire from within. That was one great difficulty to be overcome, and it has been accomplished in a very successful and ingenious manner. The bricks used in the construction of the Prince's model houses are hollow, whereby their strength is preserved, at the same time that the necessity for lath and plaster is removed, and perfect dryness secured. Their form renders them applicable, not only for side and partition walls, but for floors and roofing, and by glazing their surfaces the most ample facilities are given for cleanliness. Each room can be washed out as thoroughly when thus constructed as an earthenware dish, and fuel is not uselessly expended in warming a solid mass of material saturated with moisture. By this species of wall ventilation, which, singularly enough, appears to have been practised among the ancient Romans, the close fœted smell so offensively present in apartments that have been overcrowded for some time after they are vacated is entirely got rid of. Other advantages also present themselves, for buildings thus constructed obviously become fireproof, and hollow bricks are found to be excellent non-conductors of sound. In small confined tenements there is no greater source of discomfort than that which arises from the manner in which the slightest noise penetrates through partitions and floorings, and a simple inexpensive arrangement, which protects the quiet and privacy of the poor man's family, is a boon of immense value to him. The use of hollow bricks is thus recommended by a variety of considerations, but the chief benefit which it confers remain to be stated. By it a saving of at least one-third is effected in the expense of ordinary construction, and quite as much in fuel and annual repairs and insurance. We shall revert to this point again, and in the meantime proceed to other matters worthy of special notice in the arrangements of the model houses. One peculiarity which strikes the visitor is the avoidance of expensive woodwork and the employment of few and cheap materials to do all that is required. The plasterer and the carpenter are almost entirely dispensed with, and mineral manufactures, in one shape or other, are resorted to. Everything is of durable material, and little liable to go out of repair. There are some obvious improvements which might be made in the construction, and some economies that might be effected, for the building is, of course, experimental in its character, and does not claim perfection, being undertaken by His Royal Highness principally to stimulate the efforts of those whose position and circumstances enable them to carry out similar undertakings. Viewing it as a whole, however, the visitor will not fail to observe that it is a good working model, not a mere prettiness expensively got up and inapplicable to practice, but a sincere, honest, and sensible attempt to supply a design for the style of architecture suitable to the labouring classes and within their means to command and pay for. It is adapted for the occupation of four families of the class of manufacturing or mechanical operatives residing in town or near it. Each tenement is arranged on precisely the same plan, having a well-lighted lobby or porch, a living room, a scullery, a watercloset, and three sleeping apartments, all simply but effectually provided with convenient fittings for domestic comfort. The separation of the sexes and of parent and child is complete. Closets, dust-bins, sinks, safes, shelves, &c., are included in the plan. The ventilation is carefully attended to, and, above all, the water-supply is not neglected. Some varieties exist in the manner of finishing the different rooms, and the public will form a better conception of the care with which the whole has been got up when we mention that nearly a dozen well-known manufacturers and makers have been laid under contribution for suitable materials. We now come to the questions of expense and profit, from rent, upon which, of course, the success of the experiment turns. The calculation on this subject is, that a building of the kind can be erected for £400, or about £100 for each tenement, and that a payment of 1s. per week for each room, or about 3s. by each family, would pay 7 per cent., and cover all contingencies. Now, any one who knows what the house-rent of the labouring classes in London is must regard this as a very successful result. In Church Lane, St. Giles's, 3s., 4s., and 5s. per week are paid for single rooms of the same size; and in these abodes of vice and misery malignant fevers, and every form of epidemic disease, are constantly at work, doing frightful havoc. Let any one who wishes to understand, in its true siguificance, the importance of that movement for improving the condition of the labouring classes, over which Prince Albert so appropriately presides, after paying a visit to the model houses at the Knightsford barracks, go direct to Carrier Street, or Church Lane, or Kennedy Court, St. Giles's, and he will learn an instructive lesson from the contrast thus presented to him. He will be moved with compassion at the spectacle of such squalid misery, and with gratitude that at the Great Exhibition of the world's industry the hard lot

of those who toil in the lowest grades of labour is not forgotten. At present the model houses are only accessible by order,* but we trust soon to see them unreservedly thrown open to all comers. It is only in that way that those whose comfort they chiefly provide for can see them properly, and until the humbler classes themselves enter into the schemes and plans for their social improvement, entertained by those above them in station, little real progress can be made."

As to infant schools, they are very useful, and should be planted in different localities ; but as to the suggestions of public nurseries, the plan, to my mind, is objectionable, and would withdraw tender infants too much from their natural guardians, who, it is to be regretted, are now too much in the habit of leaving them, (often, it is true,) to procure a maintenance for them by working in mills, hence the temptation to dose their infants with anodynes to keep them still during their absence.

Another important improvement in a sanitary point of view, is providing, as much as possible, our new houses with adequate areas and spaces, both front and back, in order to procure due ventilation. Cottages of the working classes should be built with some respect to the health of the inmates, and should be liable to inspection by the public authorities, and never erected upon undrained plots of ground. Cellar-kitchens, perhaps, cannot be altogether dispensed with, but they are objectionable. Mills, manfactories, butchers' and chandlers' shops should not be allowed to abut upon, or be continuous with, the main streets, as they are sources of nuisance, and great eye-sores as well. Cattle markets, shambles, fish-markets, and slaughter-houses, should be isolated, and never seen or allowed in the thoroughfares of a town. London, at last, is to be freed from the nuisance of its cattle market in Smithfield, the existence of which so long in the midst of a great city, has been a standing disgrace to it. Paris and other continental cities, though behind us in many sanitary regulations, have long had their cattle markets and slaughter yards at a distance from the heart of the city. Public waiting rooms are also at last to be established in London, the want of them has long been felt by all strangers. The lighting of our towns might be much improved, as well as the modes of paving the streets ; the use of ashes might easily be dispensed with, and gravel substituted. To carry these and similar improvements into practice, the public mind must be constantly stimulated and roused, and the local authorities having the power to carry these into effect, supported and aided in every possible way, as we know how tardy we all are individually to cast away old habits, and so we find public bodies loath to adopt improvements, until compelled from circumstances or the force of public opinion to do so. The officers of health to be appointed under the Health of Towns' Bill should be men of standing and acquirements, able to write reports and suggest remedies, and thus have some influence over the public mind. Many of the improvements now alluded to are proposed to be effected by the carrying out of the Health of Towns' Bill, but as yet this Bill is comparatively a dead letter, and few towns have availed themselves of its powers, and fewer still placed themselves in the position to render its operation useless or unnecessary.* Towns having their own improvement Acts, move slowly on with sanitary measures, though when an epidemic happens to appear, a great talk and stir is made at the time about the want of them. We should act the sure and prudent part of adopting preventive measures whilst we have the leisure and opportunity for so doing. No longer contenting ourselves with hearing of such improvements being desirable, but carry them efficiently into operation by using the scientific researches placed at our disposal, and benefitting by, and carrying into practice, the recommendations of the eminent men whose labours I have had occasion thus imperfectly to bring before your notice.

My trouble in preparing this paper will be amply repaid, if I shall have succeeded in advancing one iota, or given the slightest impetus to, the progress and extension of preventive or hygiènic science. In seeking to use the means, and enjoy the blessings and advantages a kind Providence has so abundantly placed at our disposal, in marching forward in the path of improvement—mental, moral, and physical—by improving the habits and condition, as well as cultivating the minds, of the masses, and lagging not behind in this age of enterprise, invention, and competition, we shall not fail to reap the advantage in our own times, but we shall hand down the benefits to a grateful posterity.

* Afterwards they were thrown open, and were so when I visited them.—I.

* *Board of Health.*—Some returns were presented before Parliament, from which it appears that the number of towns from which petitions have been received for the application of the Public Health Act since it has passed is 215. The total number of towns in relation to which examinations and reports have been made by inspectors, and provisional orders have been applied with the sanction of Parliament, is 46, and by order in Council, 52. That the total number of places in relation to which reports and examinations have been made by inspectors is 34, for orders in Council 12, and towns or places awaiting second inquiries or not yet reported upon to the Board is 55, and places in which the application of the Act is suspended is 12. The average expense of the local examination, the printing and publication of the reports (of which 342 copies is the average number of copies locally circulated), and of the application of the Act by provisional order, is £121, and by order in Council, £83. The average expense of passing Towns' Improvement Acts during the years 1849 and 1850 was £2,042 each Act. The total number of applications made to the General Board of Health for assistance under the Diseases Prevention Act was 1,925; of special complaints as to public nuisances, 1,279; of letters received, 18,581: of letters transmitted, from September, 1848 to May, 1851, 56,742; of Board meetings, 617; of claims to compensation examined and awarded under the Metropolitan Interments' Act, 169 parishes.

Hospital Reports.

MARYLEBONE INSTITUTION FOR DISEASES OF WOMEN.

CASES UNDER THE CARE OF DR. S. EDWARDS, ACCOUCHEUR TO THE ABOVE INSTITUTION, AND LATELY PHYSICIAN TO THE EASTERN DISPENSARY OF BATH, ETC., ETC.

Case I.—*Dysmenorrhœa from Mechanical Obstruction of a Tumour.*

S. Parkes, aged 34, unmarried, a maid-servant, was admitted May 21st, 1851. Is of dark complexion and bilious temperament; has been declining in health for

the past twelve months, having suffered much pain from leucorrhœa and menorrhagia, which was accompanied with very great pain, gradually increasing with each returning period. Up to the month of April 1850, she enjoyed excellent health, having lived in various situations since the age of 19, in her capacity of domestic servant. At the commencement of her 17th year, she first menstruated and continued healthy and "regular" to the period just named, when pains commenced the day previously to, and continued during, the first day of its flow. This was associated with much bearing down, and from this date a slight leucorrhœa made its appearance. Previous to the time of her admission she was so weakened from the menorrhagia, the dysmenorrhœa, and leucorrhœa, that she was obliged to give up her service. She has now a considerable aching pain over the sacrum, and a "bearing down," especially on standing. The menstrual flow is very profuse and accompanied with pains of a violent forcing character, which a fortnight before compelled her to keep her bed. In the intervals she has leucorrhœal discharge of a yellowish colour, occasionally quite white. She complains of dyspeptic symptoms, *e. g.*, pain after eating, flatulence, and occasional sickness. The appetite is defective. The pulse quick (96,) small, and weak. Bowels usually a little sluggish. Has been several times under medical treatment with but a slight and transient relief. The dyspeptic symptoms were subdued for a few days, as also the leucorrhœa, to return again, however, on leaving off medicines and vaginal lotions. Presuming as she had been under the care of very respectable practitioners, that all had been done for her that general remedies were likely to effect in the absence of local ones, I proposed examining the womb with the speculum. On passing up the instrument I found the cervix considerably larger than in the ordinary virgin state, and the "os," which was stretched, blocked up by a tumour of a very firm texture, of the size of a hazel nut, a portion of which projected, glans-like, beyond the lips of the "os." On passing a probe around the growth, it was found to be attached to the inside of the uterine neck, about a quarter of an inch up, by a narrow pedicle. Believing that the irritation and various symptoms were occasioned by this morbid body, it was drawn down by means of a pair of forceps and immediately excised; blood flowed to some two or three ounces, which was encouraged, hoping it might somewhat relieve the congested condition of the cervix; caustic was then applied to the divided surface and she was recommended the employment of a lotion, composed of the oxyde of lead, powder of opium, and compound tragacanth powder. Also to take an ounce of the following mixture twice daily:—R. Ferri Sulphatis, gr. xviij; Magnes. Sulphatis, dr. ij.,; Acid. Sulph. Dil., dr. iss. Infusi. Gent. Co., oz. xij. M. Fiat mistura.

24th.—There has been no bleeding worth speaking of, little more than a bare show. The leucorrhœa, under the use of the lotion, has diminished. She states that she feels better, and that the mixture improves her appetite. To continue the remedies.

28th.—Being unable to attend from a country professional engagement, my friend Dr. Wardell saw her. Some caustic was again applied to the injured surface. She is much better, and feels stronger, and is in better spirits. The lotion was directed to be continued, and powders of calumba, tartrate of soda and ginger substituted for the mixture.

June 18th.—During this interval she has very much improved in general health; she has continued the use of the powders and lotion, excepting at her "period," which came on at the usual time with diminished flow, and with the most trifling amount of uneasiness. The cervix is softer, and considerably diminished in size, and the "os" has returned to its, (I should consider,) normal diameter. There is still leucorrhœa, but to a considerably decreased amount. She complains of feeling nervous, and occasionally hysterical. To take the mixture as previously prescribed, with the addition of ten drops of the tincture of sumbul to each dose. An injection of alum, sulphate of zinc, and tannin, to be substituted for the oxyde of lead and opium.

August 20th.—She has been seen once or twice since last report, and was continuing to improve. To-day she informs me that she menstruated on the last occasion without pain, that the leucorrhœa had left, and in fact she considered herself well, and was about to enter a situation that evening. A cold-water injection was recommended her, and frequent ablutions with the same to the genitals. Discharged cured.

Remarks.—The above case presents a good illustration of dysmenorrhœa arising from mechanical obstruction. The affection had been coming on for upwards of a twelvemonth, imperfectly at first, but increasing as the uterine mischief would seem to have progressed, and, as it was immediately relieved by the removal of the tumour, there is no other legitimate inference than that it was the cause of the dysmenorrhœa. I have also elsewhere related two cases of a similar character, one of which occurred in the private practice of Dr. Wardell, and in each of which the pains disappeared with the removal of the tumour.

On looking at the case of S. Parkes I am induced to believe that something also may be attributed to the congestion and irritation of the lining membrane of the uterine body and neck. The dyspeptic and other reflex symptoms showed an amount quite compatible with this view.

That the above was a fair example of the value of physical examination, no one will doubt who will peruse its history. She had previously been under, I have reason to believe, judicious *general* medical treatment, but with scarcely a diminution in her symptoms, in fact she gradually lost flesh and strength, and was compelled to give up her ordinary avocation. The nature of her case was one that could only be dealt with successfully by manual interference, and had it been allowed to go on, and simply treated as one of menorrhagia, with dysmenorrhœa, it is probable that life would have been sacrificed by the repeated bleedings, from a prejudicial feeling towards a most invaluable mode of investigation. What the stethoscope is to the chest, the speculum

undoubtedly is to the womb; not, however, that I would uphold local, to the exclusion of general, treatment, in the diseases of the womb, for I believe that very many of the diseases of that organ are produced by a morbid condition of the general system, and should be met equally by general as by local means.

The obstruction was a small, pediculated, fibrous tumour, or polypus, of a somewhat firm texture, and of the ordinary character. It had not fully emerged from the uterine passage, but blocked up the "os," stretching this latter tightly over it. Had it been otherwise, in all probability there would have been no menstrual pains, as in a case of polypus which lately came under my notice, wherein it was suspended in the vagina by a small and thin pedicle to the lining membrane of the uterine neck; but as this case will form the subject of another communication, I shall reserve any remarks upon these tumours until then.

It will be seen that on one occasion the tincture of sumbul was had recourse to; and this opportunity is taken of stating, after very extensive trials, that I have formed a very favourable opinion of it in several of those affections in which it has been recommended. In amenorrhœa, however, I have not found it of much benefit; but in several nervous and hysterical affections, as also in atonic dyspepsia, I have several times prescribed it with very great success, after a fruitless and lengthened trial with several of the ordinary well-known remedies.

Provincial Medical & Surgical Journal.

WEDNESDAY, OCTOBER 29, 1851.

In the discussion which is now so common in all circles on the subject of the "Bloomer" costume, the opinion of medical men is constantly asked by those who come in contact with them. It is therefore, desirable that we should all carefully consider the question in its bearings on the health of our female patients, before we commit ourselves by a decided opinion; which, of course, would naturally influence our patients and their respective friends.

The advocates for the new costume contend that it is advantageous from the absence of stays, from its covering more completely the lower limbs, and from its superior cleanliness in walking through dirty or dusty roads. With the first of these arguments we have nothing to do, as there is no more necessity for stays in the one mode of dress than in the other; besides, we are inclined to believe that tight girdles, without stays, are more injurious than the more even pressure afforded by a well-made corset: and we know that if a small waist is accounted a beauty, it will be attained by pressure of some kind or other by those who are anxious to appear in a more sylph-like form than nature has assigned to them.

With regard to the better covering of the lower limbs, we certainly can see no advantage in the "Bloomer" trouser over the ordinary drawers used by the ladies of all European countries. But in the matter of superior cleanliness, we acknowledge that Mrs. Bloomer and her fair proselytes have a decided advantage. There can be no doubt that the long sweeping skirt of our modern belles is a very dirty appendage, and we should rejoice to find it replaced by the short petticoat in fashion fifteen years ago.

Against this solitary advantage we have to adduce its unfitness for the peculiar infirmities of the sex. All the secretions in the female require a different management of dress from that of the male, in order to prevent the soiling of the material of which that dress is composed; and we are strongly of opinion that for this reason alone the "Bloomer" costume will never become general among those who value personal cleanliness and delicacy. We need not descend to particulars in order to render this clear to any one who will consider the difference between the cut of the "Bloomer" trouser and the ordinary drawers of our ladies. These latter articles would certainly be hardly compatible with the short petticoat proposed by Mrs. Bloomer, for in a high wind a considerable exposure of the person would inevitably take place; whilst the trouser if cut in such a way as to suit a short petticoat would interfere with the cleanly passing of the excretions, as we before remarked.

In addition to these reasons we may adduce the unsightliness of the frock and trouser in a state of pregnancy. We should recollect that the Turkish costume, from which Amelia Bloomer has taken her pattern, is adopted in a country where the females are secluded in the harem, and where a pregnant woman is rarely submitted to the public gaze. In Europe, on the contrary, air and exercise are in that interesting state considered more than usually necessary; and we confess that we have no wish to see our ladies perambulating the streets when about to become mothers in the dress now

proposed for them. The petticoat open in front would certainly not then be becoming, nor would it suit the portly dowager of fifty.

For these reasons we should hesitate before we advised our female friends to change the pattern of their habiliments. There is no doubt that many of them, in vulgar parlance, would like "to wear the breeches;" but we think that those of them who have sense enough to consider the subject properly, will come to the conclusion that the attempt at masculine dress is as unfitted to their bodily weaknesses as are the habits and thoughts of the male sex to the mental peculiarities of their fairer and better halves.

Reviews.

On Excision of the Enlarged Tonsil, and its Consequences, in cases of Deafness; with Remarks on Diseases of the Throat. By WILLIAM HARVEY, M.R.C.S., Eng., Surgeon to the Royal Dispensary for Diseases of the Ear, &c.

IT has often been our lot to hear complaints that the medical officers of hospitals and dispensaries (of the latter especially) are not sufficiently communicative to the profession at large, with regard to their experience and clinical observations. And this has been alleged with considerable show of justice against certain dispensaries of the special character, which from their peculiar position present rare opportunities for the advancement of medical or surgical science. We have no intention at present of naming any particular dispensary which has thus virtually closed its portals against professional inquiries, but at all events Mr. Harvey has, in the volume before us, vindicated the propriety of his appointment to the Royal Dispensary for Diseases of the Ear, by giving to the profession the results of his experience on a subject of great practical importance, viz., the treatment of deafness by excision of the enlarged tonsils as the supposed cause of the infirmity.

Mr. Harvey denies that deafness ever presents a justifiable occasion to remove the tonsil glands. To demonstrate this proposition appears to be the main object of this publication. He tells us that his experience has led him to the following conclusions:—

"1. That the enlarged tonsil, or elongated uvula, does not, *per se*, give rise to imperfect hearing.

"2. That the extirpation of the tonsil does not only not remove deafness, but on some occasions causes it.

"3. That in cases wherein the tonsil is enlarged, the disease is in the mucous membrane generally, and that its morbid condition, when remediable, is so only by means of judiciously-regulated constitutional treatment.

"4. That the tonsils are not merely secreting organs, but play a further and most important part in the animal economy, holding as they do most intimate sympathies with important, though distant organs.

"5. That extirpation of the tonsils in the young has led to pernicious results, such as giving rise to bronchial and pulmonary disease, with other mischiefs, to be mentioned in this work; and notwithstanding high authorities in favour of extirpating the tonsils or uvula for the relief of deafness, the operation has almost uniformly proved a failure."

He then proceeds to establish these conclusions by detailing several cases, which certainly bear very strongly on the various points at issue. On the connexion between the tonsils and the sexual organs in both sexes, and the disregard of this important physiological fact by thoughtless operators, Mr. Harvey makes some very pertinent and important observations. The loss of the tonsils appears to have created wasting of the testicles in the male subject, and an equally atrophied condition of the mammæ of females who have been thus mutilated. The sympathy existing between the parts about the pharynx and the generative organs has not wholly escaped the notice of physiologists, but we believe Mr. Harvey was the first who brought it forward as a practical objection to removing the tonsils.* And it occurs to us as a confirmation of the existence of this sympathy, that a French author observed in a late number of the *Gazette Médicale*, that the bromide of potassium, which, given in small doses, possesses the power of inducing a state of insensibility of the palate and fauces, has also the power of inducing torpidity of the genital organs.

That the enlarged tonsil does not, *per se*, give rise to imperfect hearing, the author proves by quoting three cases in which the tonsils were considerably enlarged, in two of them from childhood, without in either case being accompanied with deafness in any degree. And he adds another case in which the left tonsil only was enlarged, and the hearing was perfect in the left ear, though defective in the right. Every practitioner must have met with many cases of tumid tonsils in which the hearing was unaffected.

* Dr. Laycock has given his attention to this subject, and furnished some important observations, of which Mr. Harvey appears to have fully availed himself.

Kramer (quoted by Mr. Harvey) altogether denies that the Eustachian tube can be closed by enlargement of the tonsils. That the extirpation of the tonsils sometimes occasions deafness, is not less evident, and the author has not failed in producing cases in proof of this. He proceeds to show also that the voice often suffers materially from the loss of the tonsils, an important consideration truly, especially in the case of public speakers or singers.

Our space will not allow us to accompany the author further. We recommend our readers to examine well his views, and not to remove, without urgent occasion, organs, or even parts of organs, which are not, as he observes, merely lumps of flesh which may appear in the way, not *merely* salivary glands, but organs which are charged with most important functions and sympathies, of which the entire economy is not yet well enough understood to justify inconsiderate mutilation.

Although it is evident, from the occasional marks of careless composition, and the absence of nice methodical arrangement, that our author is no hacknied book-maker, yet he has given us (what is much more valuable than a well-cooked hash) a very sound and instructive treatise, evidently founded on ample observation, and abounding with valuable illustrations of the physiology and pathology of the organs on which he writes.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

JULY 3RD, 1851.

JAMES RUSSELL, ESQ., IN THE CHAIR.

Aneurism of the Left Ventricle of the Heart, bursting by a large Rupture.—By Mr. HILL.

A FEMALE, aged 26, who had been a prostitute, but not intemperate, and who had for the last six weeks gained her living by shoe-binding, had felt herself poorly, and been under the care of a surgeon, but for what I could not learn. She was taking tea, had the cup to her mouth, when she suddenly dropped it, fell to the floor, and died. I could not learn that she had suffered from symptoms of heart disease.

Post-mortem.—The pericardium was full of blood. On the left ventricle of the heart there was a large aneurism, the walls of which were thin, and had burst. There was a rather copious deposit of fat around the base of the heart and over the right ventricle, but none upon the aneurism. The aneurism was about one inch and three quarters in diameter; at its base somewhat conical in shape. It projected close to the base of the heart, was quite free from fat or adhesion, and stood out clearly, so that at first it was mistaken for a collapsed auricle. The rent by which it had burst passed across the most prominent part, and was an inch long; it formed somewhat of a flap. The walls of the aneurism were thin, and by the microscope destitute of any muscular fibres; they contained small patches of ecchymosis. The opening into the aneurism from the interior of the heart was from the upper part of the left ventricle to the left of the aortic opening, and rather on a lower level; it was separated from the aortic opening by a prominent muscular bundle, at the upper part of which, and close to the septum, was a second pouch, capable of containing a good sized pea, lined by the serous membrane, and leading towards the posterior aspect of the pulmonary artery. The opening into the aneurism was circular, rather less than the diameter of a threepenny piece, perfectly smooth and regular, and had just the appearance of the aortic orifice without the valves. The lining membrane of the heart at the place was clear and healthy; no cessation of muscular tissue could be *seen* at the opening, but a prominent ring, sensible to the finger, indicated that the muscular fibres ceased at the opening. The cavities of the heart were large, chiefly the auricles and the left ventricle. The lining membrane and valves quite healthy. A thick *tâche blanche* was on the exterior of the right ventricle. The ascending aorta natural, and free from atheroma. Coronary arteries healthy.

By the microscope. By Dr. Russell.—The muscular tissue was quite free from fat *in the sheath of the ultimate fascicles*, though there were numerous globules of fat lying *loosely* among the tissue in the neighbourhood of the aneurism, but not at a distance from that place. The transverse striæ of the fascicles were generally distinct and natural; the tissue of the fascicles seemed less clear and distinct near the aneurism than elsewhere, but as the specimen had been preserved in a fluid for some time, a positive opinion could not be given on this subject.

The preparation has been presented to the Museum of the Sydenham College, Birmingham.

Large Fibrous Tumour from the Dura Mater embedded in the Brain; Sudden Death. No preceding Cerebral Symptoms.—By Mr. DAVIS.

Mr. Davis was not called in during the woman's life. It was an inquest case. The only history which he could learn was from the daughter of the deceased. The patient was 45 years of age, (by name Sanders.) She had enjoyed a tolerably fair share of good health. Within four days of death she had walked from Bloomsbury to Camp Hill. She had not been in the habit of complaining of any head symptoms. On the night preceding her death she complained of vertigo, accompanied with sickness, which the daughter mistook for a bilious attack. When her daughter awoke, at 4 A.M., she

heard a rattling in her mother's throat; thinking she was only sick, she got up, procured a light, and on proceeding towards her mother found her dead.

The *post-mortem* examination revealed the presence of a tumour resting in a hollow of the right hemisphere of the brain. The brain itself was absorbed to the extent of the inside of an *ordinary egg cup*, and lined by a membrane on which the tumour rested. The tumour was not adherent to the brain matter, but grew from the inner layer of the dura mater. The other organs were not inspected in consequence of extreme decomposition. There was an increased amount of serum found.

Interstitial Absorption of the Neck of the Femur.—By Mr. Moore.

The subject of this disease was a man about sixty years of age, admitted into the Queen's Hospital, under Professor Cox, for an affection of the hip. The limb was found shortened one inch and a half, and the great trochanter was nearer the anterior superior process of the ilium than its fellow. The toes were turned outwards, and there was but little motion of the joint. He had little or no pain, and managed to hobble about with the aid of a stick. Whilst in the hospital he had an attack of sthenic bronchitis, which terminated fatally. The preparation is a good specimen of absorption of the neck, and it is remarkable that the patient did not attribute its origin to any blow or other injury. There were no bony deposits externally to the joints.

Fracture of the Neck of the Femur within the Capsule. By Mr. Moore.

This preparation exhibits a fracture of the neck of the femur internal to the capsule. The fractured portions were united by ligament which has been lost during maceration. The position of the limb was similar to that of the former case, the toes being turned outwards and shortening being present. From the history of the case it appeared he had met with an injury some ten months back, but had not been treated for fracture, having applied to some quack for relief. The cause of his death was an attack of acute apoplexy. His age was 53.

Caries of Vertebræ; Lumbar Abscess.—By Mr. Moore.

This preparation which exhibits the ravages of scrofulous disease of the spine was taken from a patient of Professor Parker's who was admitted into the Queen's Hospital, with a large open lumbar abscess. He died from the irritative fever, consequent on the disease. The bodies of the seventh and eighth dorsal vertebræ are almost entirely gone, and the spinal membranes are exposed; the ligaments, however, still enabled the man to retain the upright posture, and consequently, there was but little curve and no paralysis during life. He was 38 years of age, and of an eminently scrofulous diathesis.

CREWKERNE AND YEOVIL MEDICAL ASSOCIATION.

In the *Journal* of the 1st of October inst., we inserted a short notice of the proceedings of this Society at their second general meeting, at which Dr. Tomkins, of Yeovil, presided. We have now received the very excellent address delivered on the occasion, and we have great pleasure in laying it before the members of the Association and our readers generally. Dr. Tomkins addressed the meeting as follows:—

Gentlemen,—On meeting you at this our first anniversary, allow me to congratulate you (or rather—you will agree with me in saying—our Honorary Secretary) on the success which has crowned his efforts in forming this Association. It is usual at meetings like the present to bring various professional topics before the members; and if, in opening the business of this Association, I advert briefly to some subjects which it appears to me may require our consideration, you will, I trust, pardon me, should I fail in the attempt to place them before you in their proper light.

1st. As regards the question of Medical Reform. More than a quarter of a century has passed since I had the pleasure of delivering my views on this subject to a very large meeting of medical men, assembled at the George Inn, Crewkerne, to consider the best means of promoting and securing some *speedy and efficient measure of Medical Reform*. It was held in the summer of 1824 or 25, and on that occasion I wholly differed from the majority, who thought that the petitions to the different Colleges and the Legislature, would secure to them the object they had in view. I believed they would never gain their point by such a course, and, at the expiration of a quarter of a century, find that my prediction was not far from right, as we at this moment stand much in the same position, in respect to the measure, as we did at that time. You will therefore naturally inquire, what plan I proposed to effect our object? and I will tell you in one word—"agitation," for by that means I have seen many important measures carried since that period; whether right or wrong I am not here to declare, but by its means the Dissenters got the Test and Corporation Acts repealed; the Catholics obtained Emancipation; the Reform Bill was carried; and the Corn-Law-League got quit of the restrictions which were laid on the staff of life.

At that time I proposed a *medical league*, suggesting that each county should form a society for the purpose of raising funds to secure the return of some members of our profession to the House of Commons, who were perfectly conversant with the laws, the bye-laws, and charters of our different Corporations, in order that they might explain them to the House, and show the Legislature our true position. I also urged upon the meeting the necessity of using their individual interest with their friends and patients, to obtain their votes for securing the return of members who would oppose any Government that may chance to be in power, until they granted our just claims, and declared that the time was come when our profession, from its numbers, importance, and standing, was as fairly entitled to some

representation in the Legislature as the Church or the Law, the former claiming the whole bench of bishops and the members for the Universities, and the latter the law officers of the Crown to watch over their separate interests. These were my suggestions, and from that moment to the present I have not written or spoken one word on the much-vexed question of "Medical Reform," but I am even now disposed to think that our position might have been different, had my views been carried out. I think we might have stood in a better position as regards the Government; we might have had more influence with that *imperium in imperio*. The Poor-law Commission, whose motto has ever been "Cheap Physic," and who in my own knowledge have, in many instances, fulfilled the old adage of "penny wise and pound foolish," having myself seen two instances of strangulated hernia, where patients sunk from sphacelated intestines, when timely operations might have saved them, and where the Boards of Guardians were most perfectly satisfied with the medical returns, which stated that the patients had died from "obstruction of the bowels," and where, no doubt, they passed a vote of thanks to Mr. So-and-so for his very kind and humane attention, for in each case the patients were visited regularly, at least twice a day, though in neither instance was the real nature of the disease discovered in time to rescue the unfortunate sufferer from destruction, leaving their wives and families as legacies to the parish. I could mention many fearful instances, but will content myself with three others only, two of which occurred in the practice of one union medical officer, and to both of which I was called in the space of a short time.

In the first, a man had received a fracture of the frontal bone, and a spiculum was driven through the dura mater into the brain; of this the union surgeon was apprised by a respectable practitioner, who was near and saw the patient directly after the accident; he, however, contented himself by applying a poultice, and giving a dose of cathartic medicine, for forty-eight hours, when the bone was removed, and the patient, as I had predicted, died of inflammation and ulceration of the brain.

In the second instance a man had been ill for nine days with what the medical officer was pleased to inform the Board was "galloping consumption complicated with bowel affection;" for I happened to see the report. When I was called in the man appeared in articulo mortis; but on examining his abdomen I found his bladder enormously distended; and on inquiry ascertained he had passed no urine for four nights and days. I sent for my son to bring a catheter, and on introducing it, drew off seven pints of highly fœtid urine. I need scarcely add that the poor fellow died from the absorption of urea into the system. Each of these patients also left their wives and families chargeable to their respective parishes.

The other case was that of a female, who had been in labour three days and nights, and I found on my arrival that the head had been in the pelvis, and resting on the perineum thirty-six hours. The bladder and rectum were both much distended. The catheter was introduced, and some warm water thrown up the rectum, which directly acted; a few minutes after which I delivered the woman with the vectis; but so great and long-continued had been the pressure of the head that extensive sloughing took place, opening the rectum into the vagina, and leaving—of all cases the most horrid—a recto-vaginal fistula for life.

In the second place I deem it right to notice the great encouragement that is given to empiricism and irregular practice of every kind; and here let me compare our situation with that of the Church and Law. In the former, no man can officiate unless he has received a regular Collegiate education, (except with the dread of the Spiritual Court before his eyes,) and been ordained; in the latter no man will be suffered to draw a deed or execute a conveyance, for five shillings' worth of property, till he has been articled and admitted according to law, or the law will trounce him severely: but show me one town in this country, and, I might almost add, one village, that is not blessed with its "quack doctor;" or point out one newspaper that does not parade the most barefaced and impudent falsehoods in the shape of advertisements, backed, too, by the names of many of the nobility, bishops, and clergy, as passports to their nostrums, and, moreover, emblazoned with a Government stamp. Now, gentlemen, this is poaching—smuggling, for I like to call things by their proper names; and I would simply ask our Legislature, whilst they are filling our gaols with prisoners for offences against the excise and game-laws—incarcerating a man for having secured an unfortunate hare or pheasant, that they would deign to look upon suffering humanity, and protect the public from those maurauders who are daily and hourly laying their nets for the unwary, and poaching on the grounds of qualified members of the profession, so much so that I am reminded of the remarks of a celebrated Frenchman and philosopher, who, after he had spent some time in this country, made this pertinent observation,—"Do you ever die in England? If so, you must be very foolish people, for I see a safe and certain cure for all diseases posted at every corner of your streets, and its truth vouched for by many great men of your country."

I could say much more on quackery in general; but it is now right to call your attention more particularly to one of the popular delusions of the day, namely, homœopathy.

And, first of all, let us examine the names of those who descend to the practice of this craft, and we shall find the majority of them are men who have been unable to succeed in the legitimate practice of their profession, and have just wit enough to know how to impose on the ignorance and credulity of the age. But I might be told that the higher classes of society patronize their system; indeed this is their boast; let me, however, ask you if there is any species of folly or humbug, which they do not patronize. I am old enough to remember when the chapel of Irving was not spacious enough to hold the nobility and other branches of our famed aristocracy, who went to be edified by by hearing him preach in the unknown tongue;—when many high and mighty ones of the land, together with many clergymen, firmly believed in the cast off fortune-teller of Exeter, "Joanna Southcote," and were in devout expectation of her promised Messiah, sending their goodly gifts to her treasury, and actually sub-

scribing for and preparing a silver cradle and swaddling clothes. Can you have forgotton that villanous quack, St. John Long, of back-rubbing notoriety, whose house was literally beset with carriages of the aristocracy, till his conviction for manslaughter? And tell me, moreover, are not numbers of them faithful disciples of Prince Hohenloe; neither has any long period elapsed since the baronial hall was considered incomplete without its tureen of "brandy and salt," which was to cure every ill, from a corn to the cholera. Have you not read of the "Black Death," and the dancing mania of the middle ages, which hurried myriads of its victims to their untimely graves? And have we not seen in this—our own day, thousands of individuals who, *were esteemed persons of foresight and sound understanding*, infected with a disease which soon relieved the plethora of their pockets, and in numerous instances reduced them to beggary—namely, the *railway mania*, when any one who could tell that two and two made four, must have known that the capital of the country was inadequate to carry out all the lines to which Parliament had given their consent and *vouched* for by the *investigations of* their committees Is not, therefore, credulity an incurable disease?

The fact is, we are living in a day, when common things are despised or thought of little worth, and hence it is that many great people of high taste and refinement have discarded "*common sense*," as a commodity suited only for vulgar capacities. Now, if a millioneth part of a grain of belladonna or aconite will arrest the course of active disease, I hold that the millioneth part of a pint of brandy, mingled with a due portion of water, ought to produce intoxication; and that, to say the least of it, and surprise Mr. Malthus, one thousandth part of our ordinarily daily allowance of food ought, upon the same principle, to support our bodies and make us grow fat. It is truly said, that weak minds are amused with trifles. The homœopaths, however, tell us that they act upon principle and conviction, and I for one should be disposed to give them some credit, *if their charges were based on the same principle*, and they took a millioneth, or even a hundredth part of an ordinary fee for their services; their *true principle*, however, is to take all they can, and give but little away. The ancient quacks in this country used to collect their dupes in the market places with drum and fife. The modern homœopaths have lately chosen the pulpit, from whence their Reverend *vice* President boldly declared to *his dupes*, "that the mission of Christ was incomplete till Hahnemann came, for till the body was cleansed of its physical evils by the help of homœopathic globules, the moral evil of sin could not be eradicated." Now, depend upon it, whenever religion is prostituted to such vile purposes, there is something at the bottom of the matter not seen on the surface, and it is fair to conclude that those who pin their faith upon the efficacy of these globules, may soon become the believers of the real presence, in the consecrated wafer; and you plainly saw the endeavour of this preacher to enforce the necessity of placing the practice of medicine in the hands of the priesthood. It is a consolation to me that although frequently requested to meet homœopaths in consultation, I have never condescended to do so, and I trust no member of this Association ever will submit to such a degradation, but that we shall, one and all, join in calling on the Colleges at once to exclude all irregular practitioners from their lists; for if the study of medicine and surgery for the last 2000 years, by thousands of the most learned men in the world, aided by their great discoveries in anatomy and pathology, by the aid of the microscope,—in physiology, chemistry, botany, and materia medica—has not enabled us to ascertain the nature of disease, and to treat it with tolerable accuracy, then let us "throw physic to the dogs;" but if, on the other hand, we are satisfied that our profession still holds its true position, and is worthy to be upheld as a scientific, liberal, and honourable calling, let us all place our shoulders to support its pedestal in that conspicuous niche in the Temple of Fame which it has so long and so worthily occupied.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

The recent meetings of this Academy have been almost entirely occupied with the discussions of two important subjects,—one "On Congenital Syphilis and its Manifestations," the other "On the Treatment of Tuberculosis of the Testicle."

We have already given some account of a memoir by M. Depaul, in which he describes a peculiar condition of the lungs as a sign of congenital syphilitic contamination. This condition consists, according to him, sometimes in a single tubercular cavity, in others of several abscesses resulting from partial inflammation. M. Cazeaux, who reported on the memoir, has examined into the question,—Whether such appearances in newborn children, are so unequivocally syphilitic, as to justify the submission of the mother to anti-venereal treatment? He inquires:—1. Whether those purulent accumulations may not have another origin than that of syphilis; and he concludes in the affirmative, believing in fact, that they are the result of simple lobular pneumonia. 2. He asks whether M. Depaul's reasons for considering these abscesses syphilitic, are sufficiently conclusive? M. Depaul's opinion rests chiefly on the fact that these abscesses have been found coincidently with eruptions of pemphigus, but M. Cazeaux refuses to admit the syphilitic nature of the latter when congenital, inasmuch as true syphilitic phenomenon do not display themselves in an infant until three or four weeks after birth.

In the discussion which ensued, M. Paul Dubois coincided in the main with the author of the memoir, in regarding abscess of the thymus, and more particularly a pemphigoid eruption at birth, as significative of syphilitic degeneration. He stated that in almost all such cases he has been able to ascertain undeniably, the prior existence of syphilis in the parents; in addition to which, the infants have frequently presented other syphilitic phenomena, such as more or less deep elliptic ulcerations, and caries of the nasal bones.

M. Ricord also took the part of the author. He stated that he had found syphilitic lesions not only in the muscles, but in the brain, liver, and lungs. That a disease which produced a specific variety of all other cutaneous maladies, should also produce pemphigus, he thought highly probable. He also entertained no doubt of the syphilitic origin of the pulmonary lesions described by M. Depaul. In reference to the treatment of the parents of infants born with the above symptoms, M. Ricord expressed himself strongly as to the advantage of submitting parents to an anti-syphilitic regimen, where the infants were repeatedly still-born or aborted, even though the parents did not exhibit any overt signs of contamination. This repeated blighting of the fœtus he considered in itself a sufficient reason for advising the treatment alluded to.

M. Cazeaux defended his report by denying that he absolutely refused to admit the syphilitic nature of the pulmonary and cutaneous lesions alluded to, in all cases. With respect to pemphigus more particularly, he showed that there was no novelty in the supposition that it was of venereal origin. A similar opinion was maintained in the last century, by Wickman and Duges. All he contended for was, that pemphigus was the expression of a cachexia, not necessarily, though possibly, syphilitic. Similar appearances might be produced in the progeny of parents debilitated by any cause, or by scrofula, and even by misery and privation. M. Cazeaux concluded his remarks by the following propositions, many of which will meet the approval of British syphilologists:—1. In an immense majority of instances congenital syphilis does not declare itself until the lapse of several weeks after birth. 2. The exceeding rarity of an incontestable syphilitic phenomena at birth should induce great reserve as to the diagnosis of eruptions at this early period. 3. Nevertheless, the coincidence of known syphilitic contamination in the parents, with such phenomena in the infant, is a sufficient ground for considering the two phenomena as cause and effect. 4. Even though pemphigus and pulmonary abscesses may occasionally be syphilitic, they have frequently other origin. 5. The parents should not be submitted to anti-syhilitic treatment, if the signs of syphilis in the infant are doubtful.

The second subject of discussion was the "*Treatment of Tubercular Ulcers of the Testicle.*" M. Malgaigne, the author of the essay, admits two forms of tubercular ulcer; one in which the ulcer is large and completely exposed, with projecting fungosities, such as is treated of by Cooper, Laurence, Curling, Syme, and others. This fungus is, however, he observes, distinguished by the fact that it is not of the same consistence throughout, but that it has many fistulous tracks, which perforate its substance, and give issue to the ill-formed pus of scrofulous suppuration. In the other form of tubercular ulcer the disease is covered by the scrotal integuments, except in one or more spots, where a fistulous opening exists, with puckered edges.

In the treatment of the first variety, with projecting fungus, six principal modes have been established; these are—compression, astringents, escharotics, ligature, excision, and, lastly, autoplasty,—that is, covering the diseased surface by the integuments of the scrotum. In the second form—the fistulous ulcer, little treatment is required when it is disposed to heal; but in obstinate cases surgeons are at issue as to the best proceedings to adopt—whether it should be stimulating injections, cauterization, seton, division of the fistulous tracks, or castration. It is in such cases that the author propounds a new operation as a substitute for castration, namely, to excise at once the diseased integuments and so much of the glands as is involved. The only objection to this is one which the author admits,—namely, that where the disease exists in the epididymis the vas defrens may be destroyed, and the testicle thus be rendered useless; but he considers that, as regards the feelings of the patient, it is better to leave him even with an useless testicle than to remove it altogether.

In reply to M. Malgaigne, M. Roux objected that he had in his memoir confounded two different lesions; one, the fungous testicle, a disease of doubtful character; the other, a well-known affection of tuberculous origin. He also reminded M. Malgaigne that in proposing his operation of partial excision, he quite overlooked the fact, that in tuberculous testicle the entire gland is deprived of its functions, and therefore that no good can accrue from its preservation. Similar views are entertained by MM. Velpeau and Robert, with the exception that Velpeau is against all operative measures in tuberculous testicle, inasmuch as it is a disease which does not compromise life, and frequently gets well spontaneously.

M. Amussat reported an additional instance of the *cure of aneurism by electro-puncture;* and an interesting memoir was read by M. Personne, "On the *Impregnation of the Milk of Animals with Mercury.*"

Gymnastic Exercises at the Hospital for Sick Children in Paris.

An interesting experiment has been for some time in progress at this hospital, in reference to the effect of gymnastic exercises on the diseases and depraved constitutions of the patients. The result, according to the statements of the *Archives Générales*, has been most gratifying. The report observes, "that a singular improvement was soon perceptible; the complexion became brighter, the muscles more firm, the voice gained power, and at the same time many local affections commenced to be cured. Thus, glandular swellings disappeared and old fistulæ closed. In two cases anchylosis of the elbow-joint was completely cured. Chorea also yielded to gymnastic exercises only."

[Although these details are full of interest, they contain nothing which might not be expected; air and exercise being well known as the most effective curative agents in scrofulous affections generally. The hint afforded by our continental neighbours will, we trust, not be lost on the originators of the Children's Hospital in London.—Ed.]

General Retrospect.

PRACTICAL MEDICINE.

Ulceration of the Internal Jugular Vein, occurring after Scarlatina.—By W. Sedgewick, Esq.

The following is an instance of one of the more rare and fatal sequelæ of scarlatina :—A child, aged four years and a half, scrofulous, had scarlet fever severely, with great tumefaction of both parotid regions, especially the left. This enlargement on the left side continued to increase, and fluctuation was detected on the 1st of September, but the matter lay deep. Poultices were applied, and continued till the 3rd inst., when a small incision was made into it, and about seven or eight drachms of pale, straw-coloured pus escaped, followed immediately by a discharge of dark blood. The edges of the wound were at once closed with adhesive plaster, and a compress, secured by a bandage, seemed to arrest the hæmorrhage. In the evening the hæmorrhage recommenced. A friend visited the patient for me, and succeeded in arresting the flow of blood by pressure with a compress and bandage carried round the head and under the shoulders, forming a double figure of 8. The bleeding broke out twice afterwards at intervals of two and ten hours respectively. On the last occasion a narrow strip of lint, steeped in Tinct. Ferri Sesquichlor. was passed between the lips of the incision, and compresses saturated with the same were secured over it by bandages as before. The hæmorrhage was now completely stopped externally; but it was evident, at my next visit in the afternoon of the same day, that it was going on internally, and the cavity of the abscess was becoming filled and distended with blood. The child was in a very exhausted state from the loss of blood and the extensive suppuration which had taken place,—collections of matter having formed on the left side of the throat immediately below the angle of the jaw, and likewise over the left clavicle, to the inner side of the acromion process, and partly extending over it: this last abscess was very prominent, and about the size of a large walnut. On the following day the abscess was greatly distended, and the surgeon determined to lay it freely open, and search for the cause of the bleeding. This was done ineffectually, and the child speedily sank. After death, the abscess was found to be very extensive, the digastric and stylo-hyoid muscles with the blood vessels, being as it were dissected out by the suppuration. The jugular vein lay at the bottom, and in its coats was a large ragged opening, which sufficiently accounted for the fatal hæmorrhage.—*Medical Gazette*, Oct. 1st.

On the Prevention of Pitting in Small-pox.—By Dr. Marks, (U.S.)

Dr. Marks, in commenting upon the best methods of preventing deformity in small-pox, remarks that the success will mainly depend upon the stage of the eruption at which they are employed. The certainty of benefit is much less after the papular stage has passed than before it, and in severe confluent than in discrete cases. The fundamental principle in every case is to abort the eruption by arresting its progress. Of all remedies for this purpose the author places most confidence in mercurial ointment. A good formula is a plaster of equal parts of this ointment and litharge, which is put over the entire face, openings being left for the eyes, nose, and mouth. The ointment may also be applied simply, being rendered of greater consistence by a mixture of starch. A preparation made by incorporating twenty-five parts of mercurial ointment, ten parts of yellow wax, and six of black pitch, is much used in France. It may be feared that the constitutional effects of mercury may be induced; but this fear is considered by the author to be imaginary.—*The Stethoscope and Virginia Medical Gazette*, July, 1851.

Treatment of Typhus by Large Doses of Quinine.—By Dr. Robert Dundas.

Impressed with the idea that the intermittent and remittent fevers of hot climates are identical with the typhus of Europe, the author has for some time treated the latter as the former, by large doses of quinine, and commonly with the happiest results. The success is in proportion to its early administration. The doses should be ten grains, given at intervals not greater than two hours. Three or four doses are generally sufficient to exert the specific influence of the medicine, which is displayed by giddiness and tinnitus. If no amendment follows the fourth dose, and the above symptoms are induced, the author advises the substitution of an emetic, after which a lapse of twenty-four hours is allowed before a repetition of the quinine. He states, however, that in most cases of uncomplicated typhus, taken at the commencement, complete and rapid success may be calculated on; but in all stages the large doses may be safely resorted to.

In confirmation of the value of this treatment the author gives the testimony of Mr. Eddomes, the House-Surgeon of the Liverpool Fever Hospital, who states "that it either cuts the fever short or prevents the accession or increase of the more formidable symptoms."—*Medical Times*, Oct. 4.

Galium Aparine in Lepra.

Dr. Winn relates the case of a gentleman who, after many years' trial of the usual treatment for lepra, found a remedy in the galium aparine, or goose grass. On making inquiries, he found that three other persons had been similarly cured, one of whom had been discharged from a London hospital as incurable.—*Medical Gazette*, Oct. 4th.

SURGERY.

On the Operation for Vesico-Vaginal Fistula.—By Dr. Hayward.

[Any information which can facilitate the performance of this delicate and difficult operation, cannot fail to be of use. We therefore give the following details of the author's plan of proceeding, by which he has been more than ordinarily successful.]

The patient being thoroughly etherized, the bladder is to be brought down by introducing a large sized

bougie (one made of whalebone, highly polished, is to be preferred) into the urethra, to the very fundus of the bladder, and carrying the other end up to the pubis. In this way the fistula is readily brought in sight. Its edges can be pared with the scissors or a knife, though usually both these instruments are required; and this part of the operation is much facilitated by holding the edges by means of a double hook. It is not difficult to dissect up the outer covering from the mucous coat of the bladder to the distance of two or three lines. The needles are then to be passed through the outer covering only, and as many stitches must be introduced as may be found necessary to bring the edges of the fistula in close contact.

Since his first operation the author has used a short needle with the eye near the point, made to fit to a long handle. The instrument, when the two parts are together, looks not much unlike a tenaculum, though not so much curved, and considerably broader near the point.

As soon as the needle is passed through one side of the fistula, it is immediately seized by a forceps, the handle is withdrawn, and the needle is then carried through. It is to be then again fitted to the handle, and carried through to the other side in the same way. As many stitches as may be thought necessary to bring the parts into close contact can in this way be taken with great ease. One thread of each stitch is to be cut off; it is convenient to leave the other, as it enables the operator and patient to know when the ligatures have separated from the bladder.

A large-sized female catheter is then to be introduced into the bladder, and secured there by means of a T bandage. The patient should be laid on her side, with the upper part of the body somewhat raised, so as to facilitate the flow of water through the catheter. This should be removed at least once in every twenty-four hours, as it is very likely to be obstructed by mucus, coagula of blood, and by occasionally calculous concretions. In three days it is safe to remove it altogether, but then it should be introduced at least once every three hours, for ten or twelve days more, so as to prevent any accumulation of urine in the bladder, and consequent strain on that organ.

The diet should consist entirely of liquid, mucilaginous food; such as an infusion of slippery elm, gum Arabic and water, flaxseed tea, arrowroot, and milk and water, This diet in the author's opinion, should be continued till the ligatures come away.

The bowels should be opened by some mild laxative a few hours before the operation; but it is desirable that they should not be moved again till some days after.

The author states that he has never had any troublesome hæmorrhage from the operation, nor any alarming symptoms after it. In some cases the pain has been severe for two or three days, and once or twice it has run down the limb, apparently in the course of the sciatic nerve. When performed in the way that he has recommended, he believes it to be attended with very little if any danger, as the bladder is not subjected to any considerable degree of violence, nor any part injured to a great extent.—*Boston Medical and Surgical Journal.*

On Fracture of the Os Hyoides.—By Dr. Grunder.

The following case proves that this affection is not always so easy of recognition as it is usually considered to be. A labourer, aged 63, fell from a waggon on his face, and discharged a large quantity of blood by the mouth. He found he could not swallow, and when seen twelve hours afterwards complained of severe pain in the neck and nape, with inability to turn his head, though no injury of the vertebræ could be detected. His voice was hoarse and difficult. On attempting to drink, the fluid was rejected with violent coughing, the patient declaring he felt it as if entering the air passages. An examination of the fauces led to no explanation of this condition. The epiglottis did not, however, appear to completely close the larynx, or to be in its exact position. The tongue was moveable in all directions, and pressing it down with a spatula caused no inconvenience. The hyoid seemed to possess its continuity. No crepitation or abnormal moveability could be perceived, and no pain at the root of the tongue occurred on attempting to swallow. After repeated examination, the case was concluded to be one in which the functions of the nervus vagus had undergone great disturbance, or the muscles of the larynx had become torn or paralyzed. Medicine and food were administered by means of an elastic tube. The patient had a good appetite and slept well, the pain of the neck was lost, and its motion recovered; a hectic cough, from which he had long suffered, alone remaining. After continuing, however, to go on thus well for six days, the cough increased, the appetite failed, strength was lost, the voice was scarcely audible, and in five more days the patient died exhausted. At the autopsy, a fracture of the os hyoides was found. One of the large cornua was broken, and had become firmly imbedded between the epiglottis and rima glottidis, inducing the raised position of the epiglottis, loss of voice, and difficulty in swallowing. The fracture was probably produced by muscular action, a cause first assigned in a case occurring to Ollivier d'Angers.—*Schmidt's Jahrbuch*, vol. lxviii. p. 215, and *British and Foreign Medico-Chirurgical Review*, Oct. 1851.

Impaction of a large Screw in the Wrist Joint.

The following remarkable case occurred in the hospital practice of Mr. Curling:—

W. M., aged 37, was admitted into the London Hospital in consequence of a large screw which was fixed firmly in the right wrist-joint. It appears that while working at his trade as a lucifer match maker he was cutting matches with the aid of a machine worked by steam. His hand getting accidentally entangled, the large screw, which was part of the apparatus, was forced through the wrist, where it remained, and the machine being stopped, the screw was filed through, the major portion remaining in the limb. On examination, about half an inch of the screw presented itself on the dorsal aspect of the wrist. On the palmar side a wound was seen, in which was imbedded the hexagonal head of the screw, having a diameter of three quarters of an inch.

The wound was dilated with a scalpel, and after the use of some force the screw was extracted, a discharge

of synovial fluid following its removal. The limb was placed in a straight splint and dressed with water dressing. Great inflammation ensued, as might be expected, and suppuration took place, requiring the evacuation of the matter. Several portions of bone were subsequently removed, after which the wound rapidly cicatrized.—*Lancet*, Sept. 13.

Ununited Fracture treated by the Insertion of Ivory Pegs.

A patient under the care of Mr. Stanley suffered compound fracture of both bones of the right leg two years since. The bones were replaced, and put into splints for two months, and subsequently into Simpson's apparatus for four months, without union taking place. After staying eighteen months in the country he was admitted into Bartholomew's Hospital.

On examination, the fractured portion allowed of extensive motion, by the formation of a false joint. Blisters were tried for a month, without benefit, and on February 16th, 1851, Mr. Stanley determined on trying Dieffenbach's operation of driving ivory pegs into the extremities of the fragments. The patient being placed under chloroform, the bones were exposed, and two holes were bored in each fragment; into these ivory pegs were hammered, with nearly a quarter of an inch of the peg remaining external to the bone; the flap of integument was then replaced, and the limb put into the fracture box. Inflammation set in, and pus was formed; this was let out, and with it one of the pegs. The flap now cicatrized; and two months after Mr. Stanley removed the other pegs, and found that the portion in the bone had been entirely removed. The operation was completely successful.—*Lancet*, Oct. 11, 1851.

MIDWIFERY.

On the Use of Cod-Liver Oil in Puerperal Sore Mouths.—By Dr. Evans, (U.S.)

A form of disease known by this name is very prevalent in the western States of America, attacking delicate females, especially those in impoverished circumstances. The symptoms are, a burning sensation in the mouth, aggravated by hot drinks and attended with small ulcers; the bowels are generally relaxed. The disease is very apt to recur, and in some cases runs a parallel course with ulcerations of the vulva and vagina.

Observing the influence of cod-liver oil in preventing the wasting of tissues, the author thought that it might be beneficial in this affection, and experience proved it to be uniformly beneficial. The local treatment employed by him consisted of the application of diluted muriatic acid.—*North-Western Medical Journ.*, September.

On Kiestein as a Sign of Pregnancy.—By Dr. Veit.

Dr. Veit, in order to determine the value of this test of pregnancy, and to settle the discrepancy of opinion respecting it, has recently conducted a series of experiments regarding it. He has examined for this purpose the urine of ten men, four non-pregnant females, and forty-eight women in various stages of pregnancy. The result has been to decide that the so-called pellicle of kiestein is no peculiar matter at all, and of no value as a test of pregnancy. He found that the main difference in the urine of pregnant and non-pregnant women was, that in the former it was alkaline, and in the latter generally acid.— *Zeitschrift für Geburtskunde*, and *British and Foreign Medical Review*, October.

TOXICOLOGY.

Poisoning with Turpentine.

Mr. Johnson relates the case of a child, aged eighteen months, who was observed to take a cup containing oil of turpentine, which was being used by a servant, and to hastily drink from it a portion of its contents. The child immediately spluttered out the food which she had been eating, along with a small portion of turpentine. She appeared in pain, but was almost immediately soothed to sleep, from which she was roused in about ten minutes by a neighbour, who alarmed the parents by informing them that the child had taken deadly poison, and suggested an emetic, in the shape of a draught of warm water and melted butter, which was given, but produced no vomiting. The child at this time appeared relieved, in fact in its usual health, and was sent out to walk with a younger sister, a distance of 400 or 500 yards. On nearing home she appeared tired, and unable to walk, was carried into the house, and on being put down staggered, and fell, when she was put to bed, and a few minutes afterwards vomited freely, the contents of the stomach having a powerful terebinthinate odour. About ten minutes afterwards the servant found her in a violent convulsion, when the author was sent for. On his arrival, which was about three hours after swallowing the turpentine, he found the child had been in a warm bath.

She was perfectly insensible; the breathing stertorous; the pupils violently contracted; pulse rapid and weak; extremities and surface generally cold; countenance pallid; muscles relaxed, with occasional subsultus; no power over deglutition; and, at intervals of ten to fifteen minutes, violent convulsive paroxysms occurring, producing the most frightful opisthotonos.

Being some distance from home, and unaware of the nature of the case, he was obliged to treat it with such remedies as were at hand. He attempted to administer a mustard emetic, but being obliged to desist from violence of convulsion, he applied leeches to the temples. Under this treatment, together with free action of the bowels, the child became partially sensible, and at length fell into a sound sleep.—*Medical Times*, Oct. 11.

Poisoning by Fleming's Tincture of Aconite.

An inquest was held in London lately on the body of an excise officer, who died from the effects of a dose of Fleming's tincture of aconite, which, it appears, he had tasted in the course of his duties. It transpired at the inquest that a case of what was called "medicated spirits" had been received from Scotland, accompanied with a permit. One of the gaugers took a bottle out, containing one-fifth of a gallon, poured a small quantity into a glass, and having dipped a piece of wood into it,

drew it across his lips. Deceased, who was present, was asked his opinion of the spirits; and it is supposed that he swallowed a small quantity, although he was not seen to do this. It was afterwards observed that the bottle had a label, on which were the words, "Fleming's Tincture of Aconite, Poison," in large letters. Deceased left the office apparently well, but in about two or three hours (for the time is not exactly stated) he was brought to the surgery of a medical practitioner in a state of exhaustion, and he died soon afterwards, evidently from the effects of the dose of aconite which he had swallowed.

The practice of importing, under the name of "medicated spirits," so formidable a poison as tincture of aconite is highly reprehensible. The "permit" ought certainly to indicate the dangerous nature of the liquid.

Correspondence.

ON MR. OWEN'S CASE OF SPONTANEOUS AMPUTATION OF THE LIMBS OF THE FŒTUS IN UTERO.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—The case reported by Mr. Owen, of Aylesbury, in the last number of your *Journal*, is interesting, as shewing that spontaneous amputation of the limbs of the fœtus in utero, may be caused by the pressure of the funis; as also that such pressure may be great enough to stop the circulation in the limb surrounded by it, without stopping the circulation in the limb itself. But I am somewhat staggered by the kind of practice pursued in the case. After evidence that the liquor amnii had all escaped, with the "os uteri well dilated," and the "pains strong and regular," we find the accoucheur giving the ergot of rye for the express purpose of bringing the presentation within reach of the fingers. Surely there was every probability that the child was lying across, and surely with that probability the only safe practice would have been to introduce the whole hand immediately, that no time might be lost in turning the child before any part of it was wedged in the pelvis. In a practice, numbering more than 1800 cases, I do not recollect meeting with more than one case of head, breech, or feet presentation, where I could not with the fingers feel the presenting part of the child with the os uteri dilated and the liquor amnii evacuated; and in that instance there was great redundancy of liquor amnii with prolapsed funis. The woman having had arm presentation in her previous labour, I was the more anxious, and therefore introduced the whole hand, immediately after rupturing the membranes, and felt the head very high up, but a strong pain coming, before I could say *Jack Robinson*, the head was forced down upon my hand and expelled. I would boldly maintain that, under the circumstances detailed in Mr. Owen's case, with an average pelvis, if the presentation had been either head, feet, or breech, it would have been within reach of the fingers, the liquor amnii having been long evacuated—that, *therefore*, there was every probability of preternatural presentation of some kind requiring rectification—that that rectification was more likely to be easily accomplished if attempted while the fœtus was wholly above the pelvis;—that the accoucheur proved that he thought so by endeavouring to restore the child to the position above the pelvis which he had needlessly disturbed;—that the ergot ought never, under any circumstances, to be given until the presentation has been clearly made out—certainly not for the purpose of bringing a possible mal-position within reach of the fingers, because in exact proportion to the extent to which the accoucheur succeeds in effecting that object, will he find that he has baffled himself in what must be his next; for I cannot conceive a case in which turning would be more difficult than one in which the attempt is not made until the arm and shoulder have been wedged into the pelvis by uterine pains, urged into increased and perhaps incessant action by the ergot of rye. That the case in question terminated well, was certainly "more by good luck, than by good looking to"—to use a phrase in vulgar acceptation.

I am, Sir, your most obedient Servant,

October 20, 1851. Ξ.

HOMŒOPATHY.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—I wish that your correspondent, Dr. W. Davies, or some one who fully understands him, would explain to the profession what he really means on the subject of Homœopathy.

For my own part I cannot make out to my satisfaction the drift of his letter on the subject. He advises us to study the heresy, as he calls it, *theoretically* and *practically*, the very thing which the homœopathists themselves are courting us to do. Yet I am unwilling even to suspect that he is making an insidious attempt to promote a system which he is ostensibly opposing.

Accepting, however, his declining at Brighton to co-operate with the Association in the resolutions that were passed there, with a spirit that is discernible in his letter in your *Journal*, one cannot help apprehending that, at least, he is by no means hostile to the existence of that *heresy* as a rival to the profession. Dr. W. Davies does not dispute the right of the Universities and Colleges to denounce homœopathy root and branch, and cut off and eschew all members of the profession who countenance it; but he does not concede the same privilege to the Provincial Medical and Surgical Association, numerous and powerful as it unquestionably is. He apparently thinks that the proper mission of the Association, in annual meeting assembled, is simply a reciprocity of scratching, and possibly, in his opinion, *laudari laudatis viris*, would be a very appropriate motto for the said Association.

To settle the general ethics of the profession with respect to homœopathy, is a work that the Doctor seems disposed to arrogate to himself; and notwithstanding what the Colleges and Universities and the Association have done upon the subject, he lays it down, *ex cathedrâ*, that it is the duty of the profession to

study the HERESY *theoretically* and *practically*, that individual members may be able to *argue* upon it *scientifically*. Thus does the Doctor elevate the HERESY to rank as a branch of *science*, which, for so far, is decidedly an encouragement.

In such argumentations, the Doctor forbids all calling of names, and emphatically prohibits *sneerings* and *sarcasms*.

There must not be even, as we suppose, a shrug of the shoulders, with or without a grimace, when homœopathy is the subject. On the contrary, all must be done by *courtesy and intelligent reasoning*.

Reasoning with homœopathists or their patrons!! Why, what does this eminent physician mean? Does he not know that homœopathy sets reason and common sense at defiance.

Again, the Doctor further advises that those *regulars* who cannot "come to the scratch" in such intellectual conflicts with the old women, *en culottes*, as well as in petticoats, who patronize homœopathy, *masters* of the subject by *study* in *theory* and *practice*, had better hold their tongues when it comes under discussion; and he prescribes the same course for those who cannot keep their temper.

Would to Heaven I had the powers of Lander in imaginary conversation, that I might depict graphically to your readers an ideal, *courteous*, and scientific disquisition upon homœopathy, at a *coterie* in Bath, between a physician on a sharp look out for practice, and a rich old maid, scraggy and shrivelled, whilst sitting out, waiting to cut in at a whist table. Let us imagine something like this:—

Old Maid: What do you think, Doctor, of homœopathy? Do you practise in that way? It is all the rage amongst the nobility and fashionables.

Doctor: Mo, Madam. I have not hitherto adopted that system; I do not fully understand it, and I confess I have some doubts of the medicinal efficacy of infinitesimal doses of sulphur, charcoal, chalk, camomile, and other substances; but I mean to study the *science*, *theoretically* and *practically*, and to give every preparation it recommends a fair trial at every favourable opportunity.

Old Maid: Oh! Doctor, that is right—quite right. I'm so glad; for I am sure you will become a convert; and I shall have great pleasure in recommending you amongst my numérous friends. There is in Bath a fine opening for a homœopath educated as a regular physician.

Doctor: I thank you kindly, Madam, but I do not promise to become, altogether, a convert. The profession has, perhaps precipitately, rejected that system of medicine, and we are all, more or less, bound by the ethics the profession imposes upon us.

Old Maid: Don't mind, Doctor, what the profession says on the subject. The general practitioner will, of course, run it down, as they do mesmerism and hydropathy, and everything that cures without their nauseous doctors' stuff.

Doctor: Very true, Madam. I quite agree with you in that respect. I regret that some sections of the profession have treated homœopathy *very uncourteously*. They have rejected it without a scientific inquiry into its merits. Science is but in its infancy, and it *may* bring something to light in the matter of homœopathy that, in our present state of knowledge, we but little dream of.

Old Maid: You are sure to become a convert, Doctor. The wonderful cures will convince you. Have you heard of the cure that Admiral Whirlwind made of Lady Simple's favourite lap-dog? He cured it in three hours, of a violent inflammation, with three globules and a smelling bottle, when it had been given over by two doctors and the family physician!

Doctor: Very wonderful, Madam; very wonderful indeed. I heard something of it, but not the particulars. [*Rubber ends.*

Old Half-pay Captain.—Come, Doctor; come lady, cut in, 'tis your turn. [*They cut in, and all is silence.*

We may reasonably infer that the doctor is acting up to his teaching, and that he is engaged in the study of the *science*, *heresy* though it be, *theoretically* and *practically*. *Theoretically* he may study it till he reads himself half blind without harming others; but how can he study it *practically* without making his patients the victims of a system he ostensibly professes to reject as not only useless, but dangerous?

Will he venture to try and rely upon homœopathic preparations of so-called medicines in cases of acute inflammation of the viscera of the chest, or abdomen; or in similar affections of the brain or its membranes? To do so he must either have implicit confidence in the doctrines and statements of the homœopathists, or a total disregard for human sufferings and life itself.

Let it not be imagined that I am opposed to experimental practice, in cases where we have not already efficient and well-proved remedies; on the contrary, I am for giving a full and fair trial to every alleged remedy, not setting reason at defiance, from whatever quarter recommended. But, as to homœopathy, it carries on the face of it such gross and barefaced absurdities, with respect to its *pharmacopœia*, if I may be allowed for the occasion to prostitute the term, no one but the invincibly ignorant, or morbidly credulous can believe in the efficacy of the doses it prescribes. Thieves may recommend such doses, and pretend to rely upon them; but no honest man, with a medical education, can countenance such delusions, if not labouring under a delusion himself.

A recommendation to study such a farrago of nonsense *theoretically* and *practically*, and to argue upon it *scientifically* and *courteously*, savours strongly of an encouragement to the HERESY; and had such a recommendation come from a physician less eminent and less fortunate in the profession than Dr. W. Davies happens to be, one would be justified in taking it as the *avant courier* of a contemplated open conversion—as a last resource to a fashionable and profitable "*heresy*."

One would suppose that if the Universities and Colleges thought there was anything in homœopathy worth *studying*, they would have thought it worth teaching, and would, in justice to the profession and the public, have acted accordingly. One would have thought the same of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, now an authority on such subjects that the whole profession looks up to. Those learned bodies have, however, ignored homœopathy

as a branch of medical science; an example which, in my humble opinion, every individual member of the profession is morally bound to follow.

I have already made this letter, perhaps, inconveniently long for a place in your valuable Journal, yet I hope you will find room for it in an early number, and permit me to return to the subject of homœopathy on some future occasion.

I am, Gentlemen, your very obedient Servant,

AN M.D. OUT OF PRACTICE.

London, Oct. 10, 1851.

Medical Intelligence.

BANQUET TO CHARLES MAYO, ESQ., F.R.C.S.,

SENIOR SURGEON TO THE HANTS COUNTY HOSPITAL.

On Tuesday week, the 21st instant, a splendid entertainment was given to Mr. Mayo, of Winchester, by the Committee and Governors of the Hants County Hospital, to commemorate his long and faithful services to that institution. About 150 gentlemen assembled, at six o'clock, at the St. John's Rooms, Winchester, to take part in the celebration of an event so interesting and gratifying. The Rev. the Warden of Winchester College presided on the occasion, supported on his right by the guest of the evening and the Mayor of Winchester, and on his left by the Rev. the Dean of Winchester and Melville, Partal, Esq., M.P. The Committee of the hospital, with a degree of generosity which well deserves mention, presented Mr. Mayo with a very liberal supply of cards of invitation to his professional friends, and among those present and resident at Winchester we observed: — Dr. Crawford, Dr. Phillips, W. H. Judd, Esq., Surgeon in Ordinary to H.R.H. Prince Albert, and Surgeon-Major Scotch Fusilier Guards, James Mee, Esq., 1st Royals, the Medical Officer of the 38th Regiment, W. J. Wickham, Esq., R. W. Smith, Esq., who very ably filled the vice-chair, and several others.

After the cloth was removed, and ample justice done to the usual toasts, the Chairman in a very eloquent and dignified manner, next proposed the toast of the evening, and after passing in review many very interesting details connected with Mr. Mayo's deservedly successful professional career, and passing upon him encomiums which it has seldom fallen to our lot to hear, he said,—"It is my pleasing duty now to propose the health of that most excellent man, the guest of the evening, and to acknowledge the deep debt of gratitude we all owe to him for the eminent, disinterested, and brilliant services rendered to the hospital. It is due to Mr. Mayo to offer to him that sincere and just tribute of our approbation and praise to which he is peculiarly entitled. I give you, gentlemen, the health of Charles Mayo, Esq., the faithful and efficient servant of the Hants County Hospital, during the lengthened period of forty years." The toast was received with most marked and rapturous applause, and after silence had been in some measure restored, Mr. Mayo rose and said:—"Mr. Warden and gentlemen,—It has been well known to many of my friends that I had for several years past entertained an idea of the propriety of establishing a periodical festival for the benefit of the hospital; and it is indeed to me a gratifying part of my career, to find that, with a view to introduce so deserving an undertaking, the Committee and Governors of the hospital should have invited my friends and myself to partake of the good things of this sumptuous entertainment. My first and chief feeling on this occasion must be sincere thankfulness to the Almighty that my life and health has been so long and vigorously maintained, and that I have thereby been enabled to devote my services, as an humble instrument in his hand, to the carrying out the benevolent purposes of the Charity. In acknowledging, however, how deeply and keenly I appreciate the generous sentiments of esteem which my fellow-citizens have on this event bestowed upon me for the humble part I have taken in the performance of my duty, I cannot allow the occasion to pass, without tendering to my colleagues at the Hospital my warmest thanks for their excellent co-operation. To those professional and private friends who have come from the metropolis, and various parts of the country, to testify their cordial approbation of the great compliment which the Chairman and Governors have paid to me and my long services, I beg also to tender my best thanks; and with a warm sense of my unworthiness, and a sincere desire to impress upon this company and the public how much the charity is indebted to the Rev. Chairman and Committee of Governors, for the unwearied care of its best interests, I beg to propose to you the health of the "Chairman and the Committee of Governors." Mr. Mayo then sat down amidst the deafening applause of the whole company. The Rev. Chairman responded, and said, that his great happiness as a resident of Winchester was mainly to be attributed to his connexion with the Hospital. He paid a marked and well-merited compliment to the officers of the Institution. The Chairman next "proposed the Physicians and Surgeons to the Hospital." Dr. Phillips, who has been attached to the hospital thirty years, returned thanks in a very appropriate manner. Mr. Wickham returned thanks on behalf of the surgical staff of the hospital, and made some highly complimentary observations relative to the guest of the evening. The Dean of Winchester rose to add his testimony to the noble and disinterested services of the medical officers of the Charity, and said, however deserving of public approbation Mr. Mayo might be—and he believed no man was more worthy of it—he could not allow the occasion to pass without bearing his individual testimony to the high reputation and long services of the families of the Wickhams and Lyfords of Winchester. The Wickham family had rendered their services to the hospital during a period of nearly sixty years. The family of the Lyfords had attended the hospital upwards of ninety years; and to the great and vast experience of four generations of that family, he was, under Divine Providence, enabled to be present among them that evening. He much admired the talent and skill of their city. He had attended the festival at great personal inconvenience, but he had no hesitation in stating that this was one of the proudest moments of his life; for never before had he met with so many distinguished members of the medical profession,—indeed, it was the greatest demonstration of *physical strength* he had ever witnessed. The next toast was, "The Retired Physicians of the Hospital." Dr. Crawford, in a most classical and feeling manner, responded to the toast, and elicited from all present the warmest acknowledgement of his previous services. Many other toasts very complimentary to the profession were given and responded to, and the company separated, highly delighted with the occasion which had induced so many members of the profession to meet together in such harmony and good fellowship.—*Medical Times.*

MEDICAL SOCIETY OF LONDON.

At a special general meeting of this Society held on Friday, October 10, the following resolutions, recommended by the Council, were unanimously adopted:—

"1. That in the opinion of this Society the practice of homœopathy, or the prescribing medicines in what are called 'infinitesimal doses,' under a pretence that they are useful in the cure of disease, is founded in palpable error, is a delusion on the part of the practitioner, a deception on the public, and manifestly dangerous to its welfare.

"2. That the fellows of the Medical Society of London cannot honourably hold any professional communion with homœopathists.

"3. That, consequently, any fellow of this Society who shall hereafter practise homœopathy, or who shall knowingly meet in consultation any professed homœopathist, will thereby render himself unworthy of the fellowship of this Society."

THE FACULTY OF PHYSICIANS AND SURGEONS, OF GLASGOW.

At a meeting held on the 1st of September, 1851, the following minute was passed:—"The Faculty, having had their attention called to certain resolutions by the Royal Colleges of Edinburgh, in reference to homœopathy, and heard the opinion of their Council, to whom the matter was referred at last meeting, do now, in conformity with that opinion, express their concurrence in, and approbation of the views taken by the Royal Colleges, as specially detailed in the resolutions of the Royal College of Physicians; but, as none of the Fellows or Licentiates of Faculty, so far as known to them, have hitherto professed or countenanced this system, they consider any further notice of the subject, on their part, in the meantime, unnecessary.

THE SALE OF ARSENIC ACT.

Another conviction has taken place under this Act, which will eventually do much good, and be the means of saving life and preventing the commission of crime. On Wednesday se'nnight, Abraham Sefton, of Church, near Accrington, druggist, was charged at petty sessions, by the superintendent of police, with having unlawfully sold to Mary Lowe two ounces of arsenic, she not being of full age, and the poison not being mixed with soot or indigo, as required by the Act. The sale was proved, and the excuse alleged by Sefton was, that he did not know the Act was in force, and thought that the purchaser was 21 years of age. He was fined £5 and costs, the presiding magistrate, Mr. Eccles, expressing a hope that it would act as a caution to other druggists. We trust that the provisions of the Act will be speedily extended to the sale of all other poisons, so that the suicide and the murderer may be baulked in their desire for crime.—*Blackburn Standard.*

THE QUEEN'S COLLEGE, BIRMINGHAM.

The Queen's College, at Birmingham, has recently obtained powers under a supplemental charter to elect such members of the College as may distinguish themselves during their studies, and who subsequently obtain a diploma in medicine or surgery, or become graduates in medicine, law, or arts, Fellows of the College. We hear that the authorities of the College intend to confer this honour, in the first instance, upon such of the earlier members of the Institution as the Principal and Council may determine to be eligible; and in accordance with the provisions of the charter, two gentlemen, Dr. Roden, of Kidderminster, and Dr. Barker, of Bedford, have been elected Fellows of the College. These, with Mr. G. B. Masfen, of Stafford, are the first three members of the Profession selected for this distinction under the new charter. Among other privileges, the Fellows are entitled to vote at all meetings of the Governors, to free admission to the medical and general libraries, to the museums, to the lectures of the professors in the different departments, and to dine in the College Hall.

UNIVERSITY OF CAMBRIDGE.

A grace has passed the Senate of this University, to appoint Dr. Webster an examiner for medical degrees during the ensuing year. The Professor of Anatomy will commence his course of lectures on the Anatomy and Physiology of the Human Body, on the 28th, in the Anatomical School, at 1 o'clock, P.M.

UNIVERSITY OF ST. ANDREWS.

List of gentlemen who had the degree of Doctor of Medicine conferred upon them on Friday, October 17, 1851:—Robt. Beales, L.A.C., London; John Brown, M.R.C.S., and L.A.C., Islington; John Cowie, M.R.C.S., Ed., Zetland; Alexander Scott Fogo, M.R.C.S., London; Charles Gibson, M.R.C.S. and L.A.C., Newcastle-upon-Tyne; Frederick Goodchild, M.R.C.S., Middlesex; John Fred. Grace, M.R.C.S., London; Nathaniel Jarvis Highmore, M.R.C.S. and L.A.C., Bradford, Wilts; Edwin Humby, M.R.C.S. and L.A.C., London; Charles Dudley Kingsford, M.R.C.S., Middlesex; Thomas Joseph William Marsh, M.R.C.S. and L.A.C., Surrey; George Miller, M.R.C.S. and L.A.C., London; John Pearson Nash, M.R.C.S., Calcutta; John Roulston, M.R.C.S. and L.A.C., Yorkshire; Thomas Torney, M.R.C.S., Ed., Dublin; Henry Uwins, M.R.C.P. and M.R.C.S., London; John Walling, M.R.C.S. and L.A.C., Yealand, Lancaster; Henry Waldron Watson, Arnold, near Nottingham.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 10th inst:—George Atkin, Sheffield; John Breay Butcher, Devonport; Richard Cockerton, Trinidad, West Indies; Owen Spence Evans, Wilton Crescent, Belgrave Square; Thomas Beard Farncombe, Bishopstone, Sussex; Richard Croker Graves, Chester; Mark Oliver Larmuth, Salford, Lancashire; George Robinson Naylor, Calcutta; Edward Pearl, Hoxne, Suffolk; George Scott, Denmark Hill, Camberwell; Thomas Willis, Upper Ormond Quay, Dublin.

SOCIETY OF APOTHECARIES.

Gentlemen admitted on Thursday, October 9th:—James Doubleday, Blackfriar's Road; Samuel Bowen Partridge, Newport, Monmoutshire.

APPOINTMENTS.

Dr. Pereira has been appointed Physician to the London Hospital, in the room of Dr. Frampton.

Dr. Ogle has been appointed to succeed our late lamented Associate, Dr. Kidd, as Regius Professor of Medicine at Oxford.

OBITUARY.

October 7th, aged 28, Robert R. Crucefix, Esq., Surgeon, Shepton Mallet.

October 15th, aged 61, Daniel Macnamara, Esq., Surgeon, of Uxbridge, Middlesex.

TO CORRESPONDENTS.

Communications have been received from Dr. R. Hall, Mr. Prichard, Mr. Dayman, Dr. Nelson, Dr. Day, Dr. Duncan, Mr. King, Mr. Sands Cox, Mr. Wilton, and H.S.B.

A COURSE OF LECTURES ON SURGERY,

DELIVERED IN THE MEDICAL SCHOOL OF CAMBRIDGE.

By GEORGE MURRAY HUMPHRY, Esq.,

Downing College, Surgeon to Addenbrooke's Hospital.

Lecture XXXIII.

Melanic and Gelatiniform Cancer.

The nature of the pigmentary matter in melanic cancer; how far to be regarded as an important element influencing the progress of the disease; cases of the disease; order in which the pigmentary and the other elements are observed to be produced.

Anatomy of gelatiniform cancer; its resemblance in general features to the other varieties of cancer; parts most frequently affected by it; description of specimens of the disease.

The term "melanic" is applied to those cancerous tumours in which pigmentary matter, resembling that in the choroid coat of the eye, is found intermixed with the other elements of the structure. It may be contained in the cells, between the nucleus and envelope, or in the nucleus itself; in the fibrous tissue; or in the spaces intervening between the cells and the fibrous tissue. It may occur in either scirrhous or encephaloid tumours. Probably it is sometimes met with in the other varities of cancer. It is most common in the encephaloid. The proportion which it bears to the other elements of the tumour, varies very greatly. In some instances there are only a few black specks scattered through the mass; in others, it exists in such quantities as to give the whole substance a grey or dark brown, or jet black colour. Moreover, it may be equally distributed throughout the tumour, giving an uniform dark colour to the whole; or it may be accumulated at particular points, when the tumour has a spotted appearance, or presents alternating light and dark strata. Occasionally the pigmentary granules are found to be aggregated together in dense masses with scarcely any traces of organic structure; and it not uncommonly happens that a small black spot in the otherwise healthy tissue, is the first sign of the existence of the disease.

The nature of this pigmentary matter is uncertain. Structurally it is composed of exceedingly minute molecules, so minute that they are said to be capable of passing readily though membranous walls by endosmosis. Dr. Bennett has ascertained by experimenting on specimens, that the colour is destroyed by nitric acid and chlorine, "a character," he remarks, "which at once distinguishes it from the black matter which so commonly accumulates in the bronchial glands and lungs of old people, and in the black phthisis of colliers. In the latter case the black substance is undoubtedly carbon; in the former, its nature is unknown." He has little doubt that it originates in some change which the blood undergoes; for he has found it frequently, in the same specimen, undergoing all the intermediate tints from blood red and rusty brown, to the deepest black. The same author further observes, that it has been imagined to consist of sulphuret of iron, and the frequency with which old exudations in the neighbourhood of the intestines are tinged black would at first seem to favour the supposition. But in a large specimen of melanosis from a horse, tested at his request, no trace of sulphuret of iron could be found. Vogel conceives that the colouring of the so-called melanotic tumours is produced by a variety of causes; that in true melanosis, where the colour is brown, of a bistre tint, black or grey, it depends upon the presence of dark pigmentary granules, the chemical nature of which is unknown; in a false variety of mealnosis, where the colour is slate grey, or greenish black, it depends upon sulphuret of iron; and in another false variety, where the colour is blue, violet, or brownish black, it results from an altered state of blood-pigment.

It is not easy to decide to what extent this melanic deposit is to be regarded as an important element in cancerous tumours; or in what way it modifies their progress, if it does so at all. The malignant qualities of the melanic cancers depend, doubtless, not upon the presence of this deposit, but in the same manner as in other cancers, upon the abnormal tendency to cell-development, and to decay of the cellular and other elements of the mass. The melanic cancers are perhaps somewhat less liable to ulcerate than the scirrhous or encephaloid; they attain often to greater size, with less destruction of the surrounding tissues, and they infest a greater number of organs in the same individual; but it is probable that these peculiarities are dependent upon other qualities of the tumour, and are only associated with pigmentary granules in its substance. At any rate, we know that pigment-grains of a similar kind do not exert any evil influence upon the textures when they are deposited in them under other circumstances. For instance, they are often found in the skin and the mucous membrane of the bowels, when those textures have been for some time the seat of chronic inflammation; and we do not find that their presence is productive of any mischief; they appear to be perfectly inactive.

I will relate to you two rather peculiar cases of this form of cancer, which, with a single case of melanosis of the eye-ball, are the only ones that I have happened to see. A healthy-looking robust man, aged 50, presented himself at Addenbrooke's Hospital, in October, 1845, with a broad flat ulcer upon the inside of the left ring toe. It was an inch and half in diameter, had an uneven, dark, dirty surface, a hard base, and an everted livid edge. There were also in the integuments of the middle toe, and of the outside of the instep, several hard tubercles, about the size of a split pea, of livid, dark-blue, and black colour. At one part they were set together in a row, and looked, at first sight, not unlike varicose veins. The immediately surrounding integuments and other tissues were indurated. Below Poupart's ligaments were two or three enlarged and very

hard absorbent glands. Neither the ulcer, the tubercles, or the diseased glands, were at all tender or painful. He stated that three or four years previously, he had observed on the ring toe, a small hard knot, similar to those now existing on the instep. He "thought it a blood-blister, and took no great notice of it." In the last winter it had increased in size; he used to scratch it, when it bled and it soon scabbed over. It gradually grew larger, and at length ulcerated. In July, 1846, I saw this patient at Ely; he was in bed, thinner and paler than in the preceding October, but did not look so ill as might have been expected from the severity of his local complaint. The left lower extremity was covered with a number of black cancerous tubercles scattered about the skin. They were most numerous on the inside of the thigh, and the outside of the leg, but did not follow the course of any particular absorbent or venous trunks. They commenced as little black specks in the cutis, the structure of which appeared to be altered no otherwise than by the presence of the pigmentary matter, which gave the black colour to it at these spots. The spots gradually increased in size, became raised above the level of the skin and hard; some other substance, in addition to the pigmentary, being now evidently mixed up with the tissue of the cutis. The tubercles went on growing till they attained the size and shape of a split pea or bean; and in some places they were confluent, forming an uneven irregularly-shaped mass. Then a slight depression or ulcer formed at the centre, scabbed over, and again ulcerated; so that at length an uneven excavation was produced, with hard, raised, everted edge, and a thin dirty sanious discharge. Several of the ulcers were as large as a halfpenny or penny piece; and some of them were confluent. A great part of the dorsum of the foot was occupied by a deeply cleft, black or yellowish black ulcer, upon a raised hard base, with everted edges, and with foul, fœtid, dark discharge—a horrible specimen of disease, such as, happily, one but seldom witnesses. Another large ulcer of similar character had involved and partly destroyed the ring and little toes. At the upper and inner part of the leg, and on the outside of the thigh, beneath the integuments, which were adherent over them, were several hard nodulated masses, as large as walnuts or pullets' eggs. There was also a mass of enlarged and indurated glands at the upper and inner part of the thigh. The disease appeared to stop short at the bend of the groin, and though I had him stripped and examined him very carefully, no trace of it could be discovered in any other part of the body; nor was there a symptom of its existence in any internal organ, which accorded with the sound state of his general health. He died in the early part of September. No examination was made.

In this case the progress of each tubercle, and that of the disease generally, was such as is ordinarily observed in scirrhous cancer of the skin; no variation having, so far as we can judge, been produced by the addition of the pigmentary matter. The limitation of the disease to the one member which was so abundantly loaded with it, is remarkable.

The second case is that of a healthy woman, aged 46, of ruddy complexion, and light-brown hair, who came to the hospital in August, 1846, to show a black warty growth on the ulnar edge of the left palm, near the wrist, about the size of a sixpenny piece. There was no hardness about it, and it resembled a common wart, except that its situation was unusual, its colour black, and it was very tender and painful, the pain shooting up the forearm. Minute black prolongations, like spiders' legs, could be seen through the cuticle, shooting from the wart into the adjacent skin. No other formations of a similar kind, nor any enlargement of absorbent glands, could be found. She said that a small wart had existed at this spot for ten years, or more, slowly increasing in size; but of late it had become more painful. I sponged the wart freely with strong nitric acid. When the slough so produced had separated, it left a bluish, unhealthy-looking ulcer, with a dark margin. She still continued to suffer severe pain in the part and shooting up the inside of the arm to the breast; accordingly, I made a free application of potassa fusa to the ulcer and to the surrounding integuments. This left a healthy ulcer, which healed quickly, and apparently soundly, but the severe shooting pains about the arm, the breast, and the shoulder, continued for some time, though I could discover no disease to account for them. At the latter end of October the cicatrix in the palm became a little red and tender, and on its edge we observed a minute brownish spot in the skin, not larger than a pin's head. This was quite recent, and she said the disease had begun in that way. Her stomach and general health were at this time rather disordered, so she was put upon a course of medicine, and gradually got better, the pains diminished, or nearly subsided, and, though the black spot remained, the affection appeared to be so slight, that I discharged her on the 9th of January, 1847. In the early part of April, 1847, she came again, on account of an oval lump in the axilla, of the size of an egg, smooth and moveable both under the skin and upon the parts beneath. She suffered severe pain in the swelling, and radiating from it all over that side of the chest, and about the shoulder. There was still the small dark speck upon the edge of the cicatrix in the palm. We thought it better to attempt the removal of this mass, whatever might be its nature; accordingly, I made an incision through the integument, when the black colour of the tumour confirmed our worst suspicions as to its nature. When this had been excised, a number of little hard, black, round masses, varying in size from a pin's head to a nut, presented themselves in the cellular tissue of the axilla. I removed all that I could find with the fingers and the knife, clearing out the axilla nearly up to the clavicle, and then cut out the diseased integument of the palm. The tumours presented the ordinary appearance of melanosis, being for the most part of jet black colour; the large one was, in parts, of a brownish tint, or even lighter colour, and in one place it resembled the ordinary encephaloid cancer. The wounds healed, and she returned to her home, but the pains continued unabated in the side of the chest. A year afterwards,

August, 1848, being in the village where she lived, I called, and found her much wasted, and suffering severe and frequent paroxysms of pain in various parts of the trunk and extremities, sometimes in one place sometimes in another; sometimes shooting down the limbs, and sometimes like a gnawing in the bones. From her account the kind of pain she suffered resembled that which is occasionally experienced in disease of the spinal cord. There was swelling in the abdomen, and tumours could be felt in various parts of the abdominal viscera. No sign of any return of disease in the palm or axilla. She died in October, 1848. Mr. Metcalfe, the surgeon in attendance, was permitted to make only a small incision into the abdomen. He found the liver studded with white cancerous tumours, having blood infiltrated into some of them.

It is, indeed, remarkable, and contrary to what we usually observe, that the minute seed of so inveterate a disease should have remained lurking in the skin for so many years, causing no symptoms, and producing scarce any structural change. A mere darkening of the colour, and slight hypertrophy of the papillæ of the cutis, being all that was appreciable at the end of ten years; then, without any obvious cause, the part became painful, tumours formed in other regions, the strength failed, and death relieved the patient from her severe suffering. The first trace of the disease, too, it is to be observed, consisted in a mere stain or spot in the skin, caused by the deposit of pigment, (it would almost seem of pigment only,) in the tissue of the cutis. In the case first detailed the disease, that is to say each tubercle, appeared to commence in the same way. This is an interesting feature in melanosis, and it is a question, which the microscope would probably decide, whether in these initiatory stages the pigment does really exist *alone*, constituting the *sole* element of the disease, or whether it is from the very first intermingled with cells and the other ordinary components of cancer. I am disposed to believe that the former supposition is correct, viz., that in melanic cancer the pigment is often first deposited among the otherwise unaltered tissues, and that these tissues subsequently undergo the changes whereby they are reduced to a cancerous condition. In the after progress of the disease, the pigment and the ordinary cancerous elements become blended together in variable proportions, giving to the mass the different shades of colour that have been mentioned. This view is quite reconcileable with the opinion before expressed, that the malignant qualities of melanosis are due, not so much to the noxious influence of the pigment as to the reproductive and decaying tendencies manifested by the other elements with which the pigment is mixed: indeed it would seem from the case last detailed, that so long as the pigment only is present, no destructive changes take place.

Perhaps the pathology of melanic cancer may be thus expressed:—First, some deterioration takes place in the nutritive properties of the tissues, in consequence of which they become infiltrated or impregnated with grains of pigment. This condition may exist for a few hours, or for many years. It may be attended with scarcely any appreciable change in the affected tissues; it may be associated with hypertrophy of them, as in the case of the woman just related, or with atrophy and degeneration of structure. That degeneration sooner or later assumes the cancerous type; new products are formed, impregnated, like the parent tissues, with pigment, endued with much power of reproduction, and impressed with great tendency to decay, resembling, in short, both in general structure and qualities, those which are found in scirrhus and encephaloma. I do not mean to say that this order of things is invariably followed. Sometimes, no doubt, the pigmentary matter is a secondary product only, being superadded to the other elements of cancer which have been previously developed.

Gelatiniform or colloid, (from κολλη, glue,) cancer, consists of a substance like calf's-foot jelly, or glue, contained in the meshes of a fibrous stroma. The jelly-like substance has commonly a pale or straw colour; sometimes it is yellowish, brownish, or reddish. It is usually clear and transparent, but occasionally it is opaque, resembling curd or honey. Like the corresponding element of the other varieties of cancer it contains nucleated cells in the several stages of their development. The cells present a general similiarity to those found in scirrhus and encephaloma, being, for the most part, spherical or oval, containing two or more nuclei, and floating in a fluid which contains nuclei, granules, &c. In some cases the granules and nuclei only can be discovered; and in some the jelly-like substance appears to be quite structureless, containing only a few fine molecules. The tissue of which the fibrous stroma is composed differs, according to Bennett, from that of scirrhous and encephaloid cancer, in not containing permanent nuclei, or affording any evidence of being developed from nuclei or cells, but appearing to be formed by precipitation alone. It is freely supplied with blood-vessels, which often present a beautiful appearance, ramifying in the delicate fibrous septa which enclose the gelatinous substance. The fibrous septa are so arranged as to form loculi sufficiently large to be visible to the naked eye, varying from the size of a grain of sand to that of a pea or nut. They are commonly thick, and tolerably distinct; but in some parts, more particularly near the surface of the tumour, they are very delicate, scarcely or not at all perceptible without the aid of a lens, and the mass then presents a granulated or finely nodulated appearance, very much like gum Arabic.

The gelatiniform cancer presents very much the same general features as the other varieties of cancer. It invades and destroys the natural tissues, and itself undergoes spontaneous disorganization. Respecting the mode in which disorganization takes place there is some uncertainty. Inasmuch as the jelly-like contents of the loculi commonly present the same degree of transparency and softness in every part of the tumour and at every period of its growth, it would seem that the breaking down of the mass must depend either upon some changes going on in the containing stroma, or upon

the jelly-like substance being produced in such quantities as to burst the septa that enclose them. The large quantities of fluid which are not unfrequently found to have escaped into the abdominal cavity from these tumours situate on its wall may be thought to favour the latter view.

The disease is most frequently observed in women, affecting principally the abdominal organs, the stomach, omentum, the ovaries and the peritoneum. It has also been met with in the bones, in the walls of the urethra, the mammary gland, and the uterus. It may form a solitary tumour, or it may be infiltrated into the tissues; and, like the other varieties of cancer, it is often attended, in its early stages, with a hypertrophic condition of the tissue which it infests. Thus, in a case of colloid cancer of the stomach, described by Dr. Walshe, where the morbid structure was chiefly developed between the cellulo-fibrous and mucous tunics, some of the colloid loculi were observed to extend into an elevated production, which consisted of a fold of mucous membrane in a state of hypertrophy. "Hence it appears," writes that author, "that the mucous membrane, previously hypertrophous, may, as well as the cellulo-fibrous and mucous tunics, become the nidus of the diseased formation. M. Cruvelhier has made a similar observation, for he remarks that the fungous vegetations observed in the substance, or in the confines of gastric colloid, are mucous papillæ prodigiously enlarged."

There are no very marked symptoms which indicate the peculiar nature of the disease during life; indeed it has, in most instances, not been discovered till after death. In several cases where it affected the peritoneum, growing quickly and causing great distension, distress and embarrassment of respiration, fluctuation has been felt, and tapping resorted to, under the impression that the disease was ovarian dropsy, or ascites. Nor has the mistake been then always discovered, for in some cases a considerable quantity of fluid which had escaped from the growths into the cavity of the abdomen has been evacuated, and temporary relief afforded.

A cursory examination of these specimens from the museum will give you a better idea of the disease than any description. Its characters are so well marked, that having once seen an example you will be able to recognise it again without difficulty.

Here is a great mass of gelatiniform cancer which originating in the submucous or muscular coats of the stomach, near the pylorus, has burst through and destroyed the mucous membrane to a great extent, so that the granulated surface of the mass is exposed naked in the cavity of the stomach. It was taken from a man aged 40, who had long suffered dyspeptic symptoms and recurrent jaundice, but no sickness or passage of blood. The tumour had been felt during life, but its nature was uncertain.

The series of preparations which I here show you furnish examples of the disease in several organs taken from the same patient, a woman, aged about 50, who died in the hospital with abdominal tumours. The lower part of the uterus and the upper part of the vagina are quite destroyed, and their place is occupied by a transparent jelly-like substance, disposed in the cells of a delicate, reticulated, fibrous structure. These cells vary in size, being generally small. The surface of the mass is granulated, the component granules being set closely together, and adherent to one another, without any intervening membrane that the eye can detect, though the presence of a membrane may be inferred from the fact that fine vessels carrying red blood can be seen ramifying between them. In the substance of the mass, near the surface, are several opaque, white, soft, spots, like curd. The surface was covered by transparent viscid fluid. The disease does not terminate quite in a defined manner, for the lower part of the body of the uterus in contact with it is, for about a quarter of an inch, infiltrated with gelatinous granules. The vagina terminates in an irregular ulcerated edge close to the tumour, and small gelatinous granules occupy its substance for a short distance below this. I believe the patient was not known to be suffering under disease of the os uteri during life. In this instance the dissemination of the morbid product among the tissues adjacent to the tumour, and the disappearance of those tissues as the disease advanced, is very clearly shown. It is pretty certain that the process of disintegration was going on at the surface of the tumour; nevertheless the exposed granules are quite transparent, and present the same appearance as the other parts of the tumour.

In this portion of omentum, taken from the same patient, are several gelatinous grains and small, firm, nodulated masses, composed, apparently, of an aggregation of these grains, and looking very much like lumps of gum Arabic. The peritoneum covering the viscera and lining the abdominal walls was generally healthy. There were, however, under the diaphragm several circular or oval slightly-raised patches, about the size of a shilling. They had a peculiar appearance, from the central part of each being pitted, or reticulated, as though interstitial removal of fragments by absorption or ulceration had taken place.

These sections of ovarian tumours, from the same woman, are interesting, because they present at some parts the appearance of the ordinary cystic disease of the ovary, and at others that of gelatiniform cancer; moreover, they show such a gradation between the two diseases as to prove that, in this case at any rate, there is a very intimate relation between them. So again in this thyroid gland, which was also taken from the same woman, and which presents the ordinary appearance of bronchocele, the cut surface in some places so closely resembles galatiniform cancer that I suppose we must allow it to be a specimen of that disease. Unfortunately, no microscopical examination of these specimens was made, so that I content myself with simply alluding to the confirmation they appear to offer of those views of the nature and origin of cancer which I have laid before you.

In the course of lectures which is now concluded it has not been my object to give you systematic instruc-

tion in each of the several diseases that fall under the cognizance of the surgeon, so much as to communicate to you a knowledge of the general principles of the pathology of those diseases, and certain general rules, founded upon that knowledge or suggested by experience, which may be your guide in their treatment. The details of the symptoms and treatment of particular diseases have, with few exceptions, been left to be supplied by clinical instruction and observation. Neither, on the other hand, have I entered into that wide domain of pathology which, to speak in general terms, includes the morbid conditions of the circulatory and excretory fluids—a subject of fundamental importance and of daily increasing interest to the surgeon no less than to the physician—because I am aware that it is very fully brought before you in the lectures of the Regius Professor of Physic.

I have repeatedly had occasion to remind you that disease is but a result of some modification of the natural processes of nutrition; that the presence of fresh materials and the operation of new forces are by no means implied by its existence. However heterogeneous the morbid product may appear, however different its course may be from that impressed upon the natural structures, and however destructive to the neighbouring tissues and to the well-being of the body it may prove, nevertheless its nutrition is conducted on the same plan, and it follows in its growth and decay the same general laws as the normal constituents of the frame. Nay, more, I have endeavoured to give you reasons for believing that the greater number, if not all, the tumours, instead of being "new formations," as hitherto regarded, are in reality only hypertrophic conditions of circumscribed portions of the original tissues. Should more extensive and more accurate observation prove this view to be correct, much will have been done to simplify our ideas of the pathology of these masses; and when we reflect on the great advances in modern pathology effected by those who have directed attention to the diseases depending upon imperfect nutrition, it is surely not unreasonable to expect that the converse state of nutrition will prove to be highly, if not equally, deserving attention. Accordingly, a very large share of our time has been devoted to the consideration of the two great subjects, atrophy and hypertrophy. I may have appeared to lay too much stress upon them, and to have stretched them a little too far, in forcing them to embrace so many and such various products. But the more I reflect upon the matter the more convinced I feel that the *plus* and *minus æquo* of nutrition are of most extensive influence. Sometimes, indeed, I am almost disposed to think that a more accurate and deeper knowledge of physiology may enable us to arrange all morbid products under one or other of these two heads. To attempt this, however, at present would be giving generalization an undue precedence of investigation, and would savour too much of that tendency to bend facts into an accordance with theory, which is so detrimental to the true progress of science.

ABSCESSES IN THE RIGHT LOBE OF THE CEREBELLUM,

WITH CARIES OF THE PETROUS BONE.

By W. BUDD, M.D.,

PHYSICIAN TO THE BRISTOL INFIRMARY.

Read at the Quarterly Meeting of the Bath and Bristol Branch, Oct. 2, 1851.

George Bell, aged 13, of spare habit and delicate appearance, but never before the subject of serious illness, was laid up in the beginning of June, 1851, with an attack which was at first considered to be one of simple fever. Two circumstances were, however, remarked, which the sequel showed to be of great importance. These were, severe headache *chiefly confined to the right temporal region*, and a slight *discharge from the right ear*, with some deafness on the same side.

For the relief of these complaints leeches were applied to the temple and behind the ear, followed by a blister to the same spot. Salines and a few gentle doses of mercury were given internally. Under this treatment the pain abated, the febrile symptoms entirely subsided, and in the course of a few days the boy was able to return to school and resume his usual occupations. The pain in the temple, however, never entirely ceased. It was described as a dull pain, occasionally attended with *throbbing*. Up to this time there had been no vomiting, and no disorder in the motor or other powers of the nervous centres.

On the 12th of June he was again laid up, and on the following day Mr. Tribe, his usual medical attendant, was sent for. The pain of the head had once more become severe and abiding. It was limited still more strictly than before to the right temple, occupying, according to the patient's own description, a space not broader than a crown piece; it was not acute or lancinating. There was still considerable deafness of the right ear, but the discharge had ceased. In addition to this, a new symptom of great significance had made its appearance. Two days previously the speech had become thick and indistinct, and was now, at times so imperfect as to be almost unintelligible. Mental faculties unimpaired; memory accurate; no strabismus; no lateral or other deviation of the tongue; no sickness; pupils somewhat dilated, but equal and sensitive, vision good. No heat of surface; no thirst; extremities rather cold than otherwise; tongue moist but thickly coated; bowels torpid. Pulse about 100 in the minute, weak and fluctuating. Complexion pale; countenance deeply marked with the stamp of suffering.

On the following day it was observed that his gait had become insecure, and in particular that there was some dragging of the *right* leg. The face, also, was drawn, but to which side was not noted. The pain of the head had extended itself across the forehead, and the patient had become drowsy. He had also *vomited* several times, rejecting everything as soon as taken, with the exception of milk, which sat well on the

stomach. The bowels had been freely acted upon by an aperient, administered the day before.

Under these circumstances it was decided to put the patient speedily under the influence of mercury, and to employ extensive counter-irritation. With this view, three grains of blue pill were given every four hours, and a blister was applied to the nape of the neck.

On the following day four grains of iodide of potassium were given with each dose of the blue pill, and a blister was applied to the shaven scalp.

On the 16th the pain had extended to the back of the head, and there was at times double vision. The vomiting and drowsiness continued.

On the 17th, that is to say, the fifth day after the relapse, marked amendment set in. The pain had much abated, being felt in fact only when the head was moved. The utterance had become much more distinct, and the deviation of the features had disappeared. The drowsiness had ceased, and the vomiting had become much less frequent. There was still, however, some slight thickness of speech, occasional double vision, and irregularity of pulse.

On the 19th he had so much recovered as to come down stairs, and on the 20th he dressed himself and came down without help. During the greater part of this day he amused himself with his pencil, and several complicated heraldic drawings executed with a firm and clear outline, which are still extant, show better than any other evidence how entirely the right arm had recovered from the loss of power with which it had been affected.

Up to the 1st of July the amendment had suffered no check. On that day he was down stairs and running about, and quite cheerful. It is worth notice, that he occupied himself a good part of that day with a box of carpenters' tools, and that he handled them with his usual freedom and effect.

As the changes found on examination after death, when coupled with the history already given, leave no doubt that at this time one, if not two abscesses, of considerable size, existed between the folds of the right lobe of the cerebellum, such an amount of recovery as this must be looked upon as a very remarkable circumstance, and as one which might readily lead an incautious practitioner to give a favourable prognosis. The only trace of cerebral disorder that still remained, was some slight thickness of speech.

The hopes that had been raised by this favourable change, were, however, swept away on the following day, the 2nd of July, by a return of the former symptoms, in still greater violence than before.

On the 3rd of July I saw him for the first time, in consultation with Mr. Tribe, to whom I am chiefly indebted for the notes of the case.

The condition of the patient was then very striking, and characteristic of severe intracranial mischief. The pain in the head, at all times severe, was occasionally so acute as to extort moans and cries. A very remarkable characteristic of the pain was the intense degree to which it was aggravated by any, the slightest, movement of the head, voluntary or communicated. The dread he showed at every such attempt could not be readily forgotten by any one who had once witnessed it. The chief seat of the pain appeared to correspond with the base of the occipital bone on the right side, although, in less severity, it affected the whole head. His brow was deeply knit, and his whole aspect bore the impress of great suffering. He was very drowsy, withal, so that his whole time was divided between dozing and acute pain. He yawned frequently. His pupils were much dilated, but equal and sensitive, and he was very intolerant of light. There was no discharge from the right ear, and with that ear he could hear the ticking of a watch at the distance of several inches. Everything he took, whether in the shape of food or medicine, was vomited as soon as swallowed. The pulse varied, but at the time of my visit gave only forty strokes in the minute. The belly was deeply sunken and retracted; the skin peculiarly dry and harsh. The grasp of the right hand was thought to be somewhat less firm than that of the left, but there was no impairment or loss of motor power (in the way of paralysis, that is,) in any other part. His mind was clear, and memory good. His speech was thick, but sufficiently intelligible. There had been no fit or convulsion from the first. The urine was scanty, and of high specific gravity, throwing down on being boiled, a precipitate which was immediately redissolved on the addition of nitric acid. The tongue was coated with a thick yellow paste. From this time to the 7th of July there was little change, except that the vomiting became gradually less urgent. On that day, to the surprise of all, he began, for the third time, to mend; the pain in the head abated, the drowsiness lessened, and the sickness became less and less frequent. From this time he steadily improved, and on the 13th July was so much better, that it was agreed I should suspend my visits for some days. The head was now almost free from pain, he moved with ease and freedom, and the vomiting had quite ceased. His utterance had become much clearer; his tongue much cleaner; he began to take light nourishment, with relish; his bowels, for the first time, acted without medicine. Although there was nothing amounting to paralysis, he had still a more perfect use of the left than of the right arm, so that he fed himself, for instance, by preference with the left hand.

On the 14th he was put in a warm bath, which he enjoyed much, and on being taken out he stood for some time, leaning for support against his father's shoulder. This amendment was of short duration.

On the following day he became much worse. Several times during that day he was seized with severe paroxysms of pain, lasting many minutes. During this time the eyes were fixed, the pupils became gradually more and more dilated, and presently the agony merged into unconsciousness. He then lay for some time in a state of deep stupor, from which he gradually recovered. Although there was no convulsion, each of these attacks was followed by great exhaustion.

From this time he lingered, with very little change, and no new phenomena, until the 17th July, when he

expired, rather suddenly, after one of the paroxysms just described.

The powers of the left hand and arm were unaffected throughout, with this single exception, that for a short time on the 9th of July the fingers were spasmodically bent on the hand. He helped himself to a cup of coffee without difficulty with that hand about half an hour before his death.

The principal agents employed in his treatment were blisters, and mercury both internally and by inunction. Latterly opiates were given to lull the pain, and alkalies for the sickness, but these last had little or no effect.

The body was examined twenty-six hours after death. On opening the head the ventricles of the brain were found to be enormously distended with perfectly transparent serous fluid; the quantity was not measured, but must have amounted to at least half a pint; one of the ventricles was, in fact, accidentally opened by the saw, in removing the scull-cap, although the brain was by no means deeply wounded. The convolutions of both hemispheres were so much flattened by the pressure, that the sulci between them were entirely effaced. On pursuing the examination, the explanation of this state of things was found in the condition of the venæ Galeni, which were flattened, and contained no blood; the return of blood through them had been obstructed by the pressure of underlying disease, and dropsy of the ventricles had resulted. A few transparent, and very minute granulations, which were only visible when looked at obliquely, were scattered over the arachnoid at the base of the brain. With this exception the state of the cerebral membranes, whether of the surface or ventricles, was perfectly normal; they presented no trace of inflammation, and the structure of the brain itself was sound. The inferior aspect of the right lobe of the cerebellum was attached to the *dura mater* by slight adhesions. On further examination this lobe was found to be the seat of three distinct abscesses; of these, two were situated between two of the deep folds which traverse the lower surface of the cerebellum. It is important in reference to the history of the case to remark, that their presence involved no breach of fibre or other structure, although from their size they must have exerted severe pressure on surrounding parts. One of them was about the size of a Spanish nut, the other would have easily contained a large walnut. Both were lined by a distinct membrane, of new formation, to which a layer of concrete pus of some thickness was adherent. These characters were best marked in the smaller of the two abscesses, which, if any inference may be drawn from such appearances, seemed to be the older of the two. The third abscess was still larger, and was formed at the expense of the substance of the cerebellum itself. The central part of the right lobe was almost entirely converted into pus, so that the whole of this lobe might be represented as a bag of matter, whose walls were formed by grey substance. The small portion of white substance still remaining was broken up, and consisted chiefly of diffluent pulp. At one point, corresponding to the root of the rhomboidal body, a small extravasation had occurred. This abscess was lined by no membrane, and had no definite wall, the part in which the suppuration was complete shading off gradually into broken-up nervous tissue. The pus it contained was also much more fluid than that of the other abscesses. From these characters there can be little doubt that it was the most recent of the three. The left lobe and other parts of the cerebellum were free from disease. On examining the interior of the scull itself, a yellow spot, about the size of a pea, was discovered over the petrous portion of the right temporal bone. The dura mater was here separated from the scull beneath by a thin layer of concrete pus lying upon the carious bone, but there was no trace of inflammation or other disease in the cerebral aspect of the membrane. Over this space the bone was destroyed in its whole thickness, so that on lightly scraping it with a scalpel the cavity of the tympanum was brought into view. This cavity was filled with opaque lymph, of a reddish yellow, but on the removal of this the proper bones and muscular apparatus of the ear were seen to be still in place. The tympanum was slightly thickened and opaque, but with this exception was sound, as was also the meatus externus. It was ascertained that the lungs were free from tubercle, and that the heart was healthy, but the other viscera were not minutely examined.

CASE OF EPIDEMIC MUMPS,

COMPLICATED WITH PAROTITIS, ORCHITIS, NEPHRITIS, ALBUMINURIA, CONVULSIONS: RECOVERY.

By JOHN BURNE, M.D., F.R.C.P.,

PHYSICIAN TO THE BATH GENERAL HOSPITAL.

Read at the Quarterly Meeting of the Bath and Bristol Branch.

The subject of this case was a young gentleman 12 years of age, of fair complexion, red hair, and in good general health. He was at school and was first seen by Mr. Giles, of Frome, on the 7th of November last, suffering from a slight cold and sore throat.

On the 10th, being the fourth day from the attack, the parotid and submaxillary glands were swollen, principally on the left side, but the health did not fail, the patient eating and going about as usual. Other boys in the school were also affected with the mumps at this time.

The swelling of the salivary glands persisted till the 22nd, (twelve days,) when it receded, and on the 24th the testicles became affected, the *left* chiefly. The tumefaction of the testicles subsided in the course of *two* days, and now a slight puffiness of the face was observed, and slight delirium was manifested during the night. On the following morning the boy was collected and cheerful, but in the course of this day there came on drowsiness, and at half-past five o'clock he was seized with violent convulsions and extreme restlessness, getting out of bed with great strength. The convulsions were frightful and continued nearly four hours, during which, first the right arm, afterwards

the left swung round with rapidity. The convulsions having ceased, the patient was left in a state of coma, there being complete insensibility and stertorous breathing.

My attendance being now requested, I reached Frome at one o'clock in the morning of the 28th, and saw the patient in consultation with Mr. Giles. I found him lying on his right side, comatose, the respiration thick, heavy, frequent, and stertorous; when roused, he opened his eyes and looked around vacantly; when asked, he gave his hand and put out his tongue, but relapsed immediately into the comatose state. The pupils were dilated; the pulse 124, rather sharp, but yielding; the tongue dry along the middle and much furred; the face had rather a doughy aspect, and, under the eyes, was œdematous, more on the right side upon which he was lying; the belly was tympanitic and the depending integuments of the right side puffy; the skin natural; the bowels open; the urine had been scanty for two or three days, and on the last occasion was passed unconsciously.

In regarding the character of the symptoms it struck me at once that the attack of convulsions was associated with an albuminous condition of the urine, but no urine being at hand, it could not be tested at this visit. The nurse was instructed to save any that might pass.

Already the patient had been bled to eight ounces, a mustard cataplasm had been applied to the scrotum, a blister to the nape of the neck, and a saline aperient administered. This judicious treatment having been adopted by Mr. Giles, and the coma having become rather less profound, it was determined to wait for a few hours the further effect of these remedies, the patient to take in the mean time a few grains of the bitartrate and nitrate of potash, and two grains of mercury with chalk.

At nine o'clock in the morning we met again and found the patient better in every respect. The coma had passed into tranquil sleep, and the boy being now awake, was sensible and coherent. The pulse was reduced to 108; the tongue moist; the belly less flatulent; and two greenish bilious dejections had passed, as also a small quantity of urine, of which about one ounce had been caught. He had taken farinaceous food. The urine being examined was pale and dingy, with a greenish tint and less refractive power than natural, characters indicating the presence of albumen, which, on the application of heat, was manifest, the urine becoming white and opaque.

From this evidence there could be no longer doubt that the pathological congestion of the salivary glands had been transferred, not only to the testicles, but also to the kidneys, and that the cerebral symptoms resulted from this complication. To the kidneys, therefore, our attention was directed

The remedies prescribed were dry cupping on the loins, bitartrate of potash in the dose of ten grains, every four hours, and chalk, with mercury, in the dose of two grains every night; and it was particularly desired that the surface of the body should be kept warm and the temperature of the chamber raised to about 65 or 70 degrees.

On the next day the albuminous condition of the urine was much diminished, and in twenty-four hours more had disappeared altogether; nor was it detected by Mr. Giles on any subsequent examination.

On the 3rd of December the boy got up, partook of some mutton, and saw his father for a few hours, after which there was some return of the head symptoms, as manifested by pain and confusion of ideas. This threatened relapse was met by Mr. Giles, by leeches, cold lotions, and aperients, and from this time the patient recovered without any further untoward symptom.

The foregoing case presents an ordinary example of epidemic mumps, in which the inflammatory affection of the salivary glands, attacking the left, more than the right side, was transferred to the testicles, the left particularly. The occurrence also of cerebral symptoms, in connexion with this metastasis, is not unfrequent, and has been the subject of remark by the few authors who have written on this disease. The chief interest which attaches to this case is the condition of the urine and kidneys in connexion with that of the brain—a connection not observed hitherto, as far as I know, there not being any allusion to the kidneys or to the albuminous state of the urine in the recorded cases of cynanche parotidea with metastasis to the brain. The great body of evidence which has been published since the discovery of Dr. Bright has confirmed his observation, and has left no doubt of the fact of the general existence of disease of the kidneys, where there is albumen in the urine, and of the additional fact of œdema, dropsy, coma, epileptic convulsions, and apoplexy supervening on, and being induced by, this condition of the kidneys and urine.

Without the convincing evidence of morbid anatomy in conjunction with observation during life, the concatenation and association of nephritis, albuminuria, and convulsions, as cause and effect, could not be maintained, so slight, and sometimes null, are the signs referable to the kidneys.

In the case now related there had not been any complaint of pain, uneasiness, or other sign in the lumbar region indicative of disease there. Nothing to call the attention to the kidneys. The presence of convulsions, the slight œdema under the eye, and the now known dependence of these phenomena on a special pathological condition of the kidneys, drew our attention to these organs, when the secretion of urine being found to be scanty, almost to suppression, and the urine itself albuminous, the precise nature of the case was revealed.

Looking at the course which the disease had taken, first, the affection of the salivary glands, which subsided, then of the testicles and kidneys, it may be concluded that the action set up in the testicles and kidneys was of the same character as that which was manifest in the parotids, namely, a pathological congestion, an inflammation, which constitutes the acute form of Bright's disease, designated by some late histological observers, *desquamative inflammation of the kidneys*, a term not free from objection, as it locates the inflammation in

the tubules, the product being degenerated epithelial cells and fibrinous casts. But, as I believe that in this acute form the proper tissue of the kidney is involved, if not the main seat, and that interstitial deposit takes place in it, as in the parotids and testicles, we may be safe in regarding the nephritic attack as an acute pathological congestion, and, as such, amenable to an antiphlogistic treatment—a point of much practical import.

Albuminuria, a main diagnostic feature in the present case, occurs also in the other form of Bright's disease, named by Gluge *stearosis*, on account of the deposition of oil-globules in the epithelial cells of the urine tubules; but this form, being chronic, does not bear on the subject under consideration.

The cerebral symptoms, regarded as arising from inflammation of the kidneys, and the consequent suppression of urine, would urge the necessity of vigilance during the course of a disease so prone to metastasis, and of attention particularly to the quantity of urine, as also to the testing of its character; and should the quantity prove to be slight, and albumen to be present, we should then not hesitate to abstract blood as the best means of arresting the threatened or existing nephritis, and of preventing the occurrence of cerebral symptoms. The abstraction of blood from a vein, and locally, is most essential, and next to it the use of diaphoretics; but mercury is admissible only as an alterative, general experience having shown that it aggravates rather than relieves, and on some occasions even produces the disease. It is important, moreover, that the surface of the body should be kept warm by suitable clothing, and that the temperature of the chamber should be regulated, especially in the cold season; and indeed, in every case of mumps, the patient should from the onset be confined to the house, exposure to vicissitudes of temperature being the frequent exciting cause of metastasis.

ON

THE TREATMENT OF HABITUAL OR CHRONIC CONSTIPATION.

By HENRY COLLETT, Esq., Worthing.

Habitual or chronic constipation is one of the most common amongst the miseries of human life: it is a "thorn in the flesh" to thousands of sufferers, while also it is a source of revenue to a vast number of advertising vendors of antibilious, digestive, and other kinds of pills, the use of which serves but to increase the evils they profess to remove; the result is, that it becomes as necessary for the sufferers to resort to the daily use of pills as to eat food, to prevent all the physical and mental disquietude consequent upon dyspepsia from constipation. But this is not the whole of my reason for bringing the subject under notice. The cases which I shall relate will prove that many of the first authorities in our own faculty, in my humble opinion, have overlooked one of the most frequent causes of the complaint under consideration, and have failed in affording relief, while the very simple treatment which I propose, founded upon what I believe to be this cause, has been most successful and gratifying both to the patients and myself. Having been a sufferer myself I can speak the more feelingly upon my subject, for "*haud ignarus mali miseris succurrere disco*," and I feel satisfied, should the treatment be generally adopted where constipation, independent of organic causes exists, the habit of daily medicating would be entirely superseded.

Case 1.—Mrs. B., an interesting young woman, aged 23, married, with one child, consulted me under the following circumstances:—She was in every other respect perfectly healthy, but for three years had not been able to pass a motion without the aid of medicine. Sometimes the evacuations were scybalous, sometimes more or less fluid, but always scanty and void of proper form. Several attempts had been made to allow nature to perform her office, but obstinate constipation and much nervous and miserable discomfort were the invariable effects. Aperients and the enema were her only comforters. I learnt that she had consulted several eminent physicians and practitioners in Paris, in London, and in the provinces. All gave her some favourite aperient, until at last one told her that nothing but a miracle could cure her. Such were the unpromising features of the cases that I scarcely ventured to prescribe, but having my own case as a precedent I tried the plan here. I prevailed upon her to promise to discontinue all aperient medicines for a week, to leave off the use of white bread, entirely to eat brown bread (made of wheat meal, only partially sifted, for some is made of rye which I do not recommend) and drink a glass of cold spring water the last thing at night, and in the morning immediately on rising. She ridiculed my advice, but adopted it. The first day past and no evacuation, but the second day gave birth to a large well-formed stool, which gave feelings of comfort and satisfaction, to which she had been a stranger for years, and every day after she had a daily relief up to the time of leaving this neighbourhood, four months after the date of commencing the treatment, during which time she took only one dose of castor oil, because she thought herself bilious, but steadily pursued the diet recommended.

Case 2.—Mr. A., habitually constipated and constantly taking aperients for years past, adopted the plan above recommended, now passes large and healthy evacuations daily, without straining or any effort, and expresses himself so much relieved that he is recommending the remedy to numerous friends. On mentioning it to a physician of eminence, an intimate friend of his, his reply was,—"Oh! you are rasping your inside;" an explanation of the plan, which in the sequel, I hope to prove erroneous.

Case 3.—Mr. G., an artist, who came here in very delicate health, had for years suffered constipation, and taken aperients for many years at least three times a week, had consulted three eminent professional men in London, besides others, and at the time I saw him had taken the senna mixture every morning for three weeks, looked haggard, and care worn. I told him my plan and the success I had met with, which he followed. A month has passed, and he has not required any further aperient, having passed daily one or two large evacuations, and he is now looking comparatively healthy. I should mention that the rectum was in such an irritable state as to create great suffering with every motion. This has quite left him.

In Dr. Copland's Dictionary, eight causes are mentioned for constipation. I shall not state them, but refer to the work (Art.—*Constipation*) for the information. The one cause above-mentioned is not found among them, viz., imperfect distension of the intestine, (I am supposing that all the collateral functions are healthy,) and this I believe to be the most common cause of constipation.

When the physiology of the intestine is duly considered, it will be evident that certain conditions are necessary for the performance of its healthy functions, and these are specially a certain degree of distension by fœcal matter, and that of such a semi-solid nature as to be easily pressed by the contracting action of the gut. If the fœcal remains of digested aliment is so small as not to cause sufficient distension, or supposing the bowel distended sufficiently, but the contents so hard as not to be impressed by its peristaltic contractile action,* none or little onward movement will take place.

The diet of the English consists of white bread, meat, in larger or smaller quantities, and vegetables, mostly potatoes, &c., and much activity in the functions of digestion; for instance, "abundance of gastric juice," "active absorbent powers," added to the easy solubility of the above-named ingesta, may co-operate in preventing the "conditions" above alluded to, not affording sufficient excrementitious matter.

Now, it appears to me the effect of brown bread is to meet this difficulty. The portion of bran it contains is insoluble, and forms a frame work of the large fœcal formation invariably following upon its use, enabling the bowel to act naturally, and in addition, stimulating the exhalents mechanically, whereby an extra quantity of mucus is thrown out to assist its propulsion; also clearing the mouth of the lacteals, thus completing the operation of digestion in a healthy manner.

To meet the vulgar prejudices against the use of brown bread, viz, that it is less nourishing than white, I need merely state that the Scotch and North of England people, who are the strongest in our island, eat oatmeal, and that brown bread is nothing more or less than wheat meal, and I quote the following article on this subject from the *Lancet*, Feb. 10, 1849, shewing that there are "*nutritive properties in bran*:"

* Or as Blumenbach calls it, its undulatory contracting motion.

"M. Millon has communicated to the Academy of Sciences the result of some interesting investigations of his concerning the ligneous matter of wheat; whence it would appear that "bran" is a very nutritive substance. Though bran, doubtless, contains from five to six per cent. more ligneous substance than flour, it presents more nitrogenous matter, twice as much fatty matter, and, moreover, two distinct aromatic principles, one of which presents the fragrance of honey; and these are both wanting in flour. Thus (by sifting) impoverishing wheat in nitrogenous matter, fat fecula, aromatic and sapid principles, in order *to free it from a small proportion of ligneous substance.*

M. Millon, therefore, thinks that bran and meal ought to be ground over again, and mixed with the pure flour; and he has found, by repeated experiments, that this mixture yields a superior kind of bread, and free from the inconveniences of that bread which in some countries, and particularly in Belgium, is made with coarse meal.

I conclude this paper with another quotation extracted from an admirable article published in the *Lancet*, Dec. 19, 1846, by Dr. Robert Dick, on the use of bread. He says:—"The use of fine bread and the systematic exclusion of all *excrementitious non-assimilable* ingredients from our articles of diet, is nothing else than an attempt, as it were, to dispense with four-fifths or more of the alimentary canal—a long and important line of excretion meant to be continually active; and the torpor of, and the withholding from which its appropriate stimulus, (to wit, the excrementitious parts of our food,) cannot but be attended, sooner or later, with serious evils."

CASE OF OVARIAN TUMOUR.

COMMUNICATED BY W. H. BAINBRIGGE, ESQ., LIVERPOOL.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—The following is the substance of a communication sent to me descriptive of a case of ovarian tumour. As it involves points of much practical importance, I deem it desirable to publish it, together with my answer.

Having previously drawn the attention of the profession to this subject, I would take the opportunity of expressing my regret for having remained so long silent, as I feel that my medical brethren are justly entitled to the results of those cases which have subsequently come under my own immediate care and management.

I remain, Sir, yours very faithfully,
W. H. BAINBRIGGE.

Liverpool, 3, Islington Square,
September 18, 1851.

" * * * The history of her case was as follows:—She first discovered a tumour in the right

inguinal region, which appeared gradually to extend over the whole abdomen. She states that she has been tapped seven times, and that the necessity for the performance of paracentesis is now more frequent, the last operation having been performed only four weeks ago; that she had been seen by Dr. ———, who pronounced her disease ovarian; that the tapping never diminished the tumour on the right side. Emaciation was beginning, but her general health appears good. I thought this a favourable case for the operation, trusting to the opinion of those who had possessed the best opportunities of judging as to the real nature of the case. * * * * An incision was made through the abdominal coverings, and the dissection very carefully made, until a white glistening substance was discovered, which certainly looked like the cyst of an ovarian dropsy. It was not laid bare more than a quarter of an inch, as there seemed to be adhesions around it. A portion of lint was introduced, and strapping applied. This was removed this morning, (the fourth day); the adhesions *seemed* to be perfect. The appearance of the part was so altered, from incipient granulation, that no cyst could be *seen*, although we easily felt what was supposed to be the sac. The trocar was introduced, and nearly a pailful and a half of transparent straw-coloured fluid escaped, very unlike the contents of an ovarian cyst. After the flow a fluctuating swelling, as large as a child's head, was seen at the right side, upon which the operation had no effect. *This* at any rate is contained in a cyst. I was afraid of keeping the wound open, feeling some hesitation about the case, and therefore closed it. I wish to know whether it would be advisable to perform the operation on the tumour now remaining, the nature of which is perfectly clear? and whether, *supposing* the clear fluid evacuated to have been contained in a *larger cyst*, the operation on the smaller will have any effect upon it? If anything be done, it must be done *quickly*, as there will soon be reaccumulation, and then the difficulty of diagnosis will again recur.

" * * * *

" To W. H. Bainbrigge, Esq."

3, Islington Square, Liverpool.

My dear Sir,—I have your letter of yesterday, and, agreeably to your request, reply to it at once. The case which you have described is very interesting, and not an unusual one. If the cyst you have tapped is really *ovarian*, the tumour which became apparent on the right side, from the drawing off so large a portion of fluid as "*a pailful and a half*," is, in all probability, a smaller sac, and is contained within the one already evacuated; for I have never yet met with a case in which right and left ovarian dropsy existed simultaneously, nor do I think such an incident probable. Assuming, then, that your case is one of ovarian dropsy, unconnected with other disease, what you should have done was, to have left open the aperture made into the *larger cyst*, when thus by setting up a new action, and eventually a suppurative discharge, the *smaller tumour* would soon have disappeared. I am as satisfied of this fact as that I am now writing. I do not believe that such a thing exists in reality as an *unilocular* ovarian cyst; smaller ones are always to be found within the cavity, or rather, are surrounded by the fibrous coat of the one most largely developed; and if suppuration is once set up in the latter, by the means which I have already endeavoured to explain to the profession, the former will soon degenerate and slough off. I have on more than one occasion drawn out from the original opening portions of sac of sufficient size to form the outer wall of a cyst quite as large as the second tumour you describe, viz., "as large as a child's head." The only question as to your present case is?—Whether you have tapped an encysted or a common dropsy?—whether the trocar passed into an ovarian sac or into the abdomen. It is possible, and not unfrequently happens, that an ovarian cyst may be co-existent with dropsy of the abdomen. If this should prove to be so in your case, you acted wisely in immediately closing up the wound into the abdomen, and you did all that could be done to relieve your patient. If, however, on the other hand, the puncture was made into an ovarian sac, and the tumour which now remains is similar in character, it is a *most favourable case* for the operation and treatment I have advocated, and I should entertain no fears whatever as to the result.

I am glad you adopted the mode I recommended in the commencement of your operation, viz., by cutting down upon and exposing the cyst for some days before puncturing it. This procedure is, I am satisfied, the safest way of going to work, is far more simple than the plan I originally recommended, and by *thus* securing permanent adhesions of the sac to the abdominal parietes, prevents the possibility of any communication with the abdominal cavity.

A case which I operated upon in February, 1849, was precisely similar to the one you have described. She was a patient of a very intelligent friend, Mr. Pritchard, of Fairfield, near Liverpool; a woman of middle age, the mother of children, and was so emaciated and debilitated at the time that we resorted to the operation with great hesitation. She, however, recovered without even one bad symptom, and is now in perfect health, and capable of pursuing her ordinary laborious avocation, that of washing.

I have for some time past contemplated the publication of the above, and other similar cases, and your letter of yesterday strongly reminds me of the duty I owe to the profession that this publication should be no longer delayed. The delay, in truth, has arisen, not alone from the urgency of my professional labours, but also from other important matters, which have lately pressed so seriously on my time and attention, as to preclude the possibility of my doing justice to a subject of such great practical importance.

If, in the progress of your case, my further advice can be useful to you, you may command me freely.

I remain, my dear Sir,

Yours faithfully,

W. H. Bainbrigge

WHAT OUR ASSOCIATION MIGHT DO.

By C. RADCLYFFE HALL, M.D.,
Torquay.

For the "Provincial Medical and Surgical Journal."

No. I.

It is impossible for the most superficial reader of the works given to the world during the last ten years by such men as Budd, Paget, Hughes Bennett, West, Jenner, and Walshe, to avoid the gratifying conclusion that a great change for the better has taken place in the mode of dealing with medical inquiries. The day of medical hero-worship is gone by. Opinions are valued only in proportion to the facts on which they rest. The facts themselves are jealously scrutinised. What Professor A. B. *thinks*, is replaced by what Professor A. B. *has proved*. What *may be*, is neglected for *what is*. There is more of scientific candour than formerly. Working men in science are not afraid to avow their ignorance on given points, and seek not to cloak it in a cloud of verbiage. A metaphysical style of stating a fact is no longer mistaken for an explanation of it. Facts alone are allowed to dogmatise. The generalisation of facts is more cautious, and in the same degree more trustworthy than of yore.

In all this there is much of hope. In proportion as medicine is rendered more exact, in proportion as we can make use of physical aids in our practical investigations, and furnish physical proof of morbid action, and of the effects of treatment, will mystery disappear, scientific attainments receive their due, and quackery lessen. To percussion, the stethoscope, the tape, the spirometer, the chest-measurer, the balance, the test-tube, and the speculum, our obligations are great. These, however, are but the means. The spirit to use them is owing to the general change in philosophical investigation which has taken place in all branches of science. Nature is everywhere asked to interpret herself. Man having too long tried without her aid in vain. Content with bepraising the inductive method and its Great Introducer, we have too generally "known the right, and yet the wrong pursued." How far Nature will reply to judicious questioning, the results obtained by Faraday in physics, and by Louis and Jenner in medicine, sufficiently attest.

Let the reader refer to any statements made by these men. They bear on their very face the impress of truth and honesty. Let him then seek amongst writers on any variety of quackery for statements in like manner obviously and self-evidently true and honest. The search will be vain. The counterfeit coin has not the ring of the true metal. Even the most credulous non-medical reader of a homœopathic work, for example, can feel no intuitive conviction that what he reads is true. Hardihood of assertion may deceive him into thinking that the statements may be true, and that their writer may himself believe them. But he can see no proof of it, nor feel any decided conviction. He reads such statements as this—"Let it ever be remembered, *purging is poisoning*," (Epps on Homœopathy, 5th Edtn., p. 116,) and remembers how salutary the poisoning of a black draught, or of a visit to Cheltenham, has sometimes proved. And such "facts" as this:—

"A patient of mine, (Epps *loquitur*,) the Baron de Bode, was attacked with a severe illness in the year 1842. He was evidently in great danger. Among his symptoms was one of a feeling of a bruised condition of the chest, affecting his breathing, producing severe pain on taking a full breath, and attended with excessive prostration. I inquired anxiously whether he had received any wound, having been a general during the continental wars, and engaged in many battles. He said no; but on reflecting, remembered the following circumstance:—As he was sitting on horseback, watching the movements of the army engaged in battle, with his aid-de-camp at his side, a cannon ball passed above his horse's head and before his breast, and taking the aide-de-camp in its course, made, to use the Baron's own expression, "a complete rag-fair of him," cleaving his body asunder. The Baron experienced a shock, and his horse was so affected that he shivered, so to speak, as to go upon his knees. The excitement of battle banished all the rest, and he had not thought of the circumstance until I had thus brought the event back to his memory. I forthwith ordered arnica internally, and an arnica poultice externally, and the change was so rapid as to convert to homœopathy a most intelligent (!) friend of the Baron's, who had been watching the case with intense anxiety; the more so, because having no faith in homœopathy, he had the greatest fears on behalf of his friend." (*Ibid.* p. 207.)

Can we wonder that amongst the entire number of homœopathists in Great Britain there is but one who, before his seduction, had given to the profession any evidence of being a correct observer, and not one who had proved himself to be a judicious and trustworthy reasoner—not one who possessed, to any extent, the confidence of the profession? What single addition to the facts of science (leaving, for the sake of the argument, therapeutics out of the question) has any one of the homœopathists made? We know of none. New modes of dealing with our patients, as well as of prescribing, they have shown us; but that, like the rest, only in matters of lucre, not of science. A certain northern homœopathist, for instance, is said to be Ambidexter in the use of his weapons; being ready to treat a patient either homœopathically or according to the precepts of rational medicine, at the pleasure of the applicant. He, no doubt, feelingly appreciates the advice—

"Rem;
Recte, si possis, sed *quocunque modo*, rem."

We have dealt unfairly with true medicine, by suffering it to be designated allopathy. Allopathy and homœopathy,—each is a "pathy." How are the public to decide that the latter is anything meaner than one of the many medical doctrines on which differences of opinion are, and were more formerly than at present, entertained? Why should we disgrace medi-

cine by giving it a designation merely antithetical to homœopathy, as if the two were parallel but different? As well might we christen our science afresh in special contra-distinction to chrono-thermalism, hygiëism, mesmerism, or Parr's pillism. We ought not to speak of homœopathy as being medicine in any sense. We ought not to forget, if the novelty-seeking part of the public sometimes do, that rational medicine comprises the use of all the means for the treatment of disease which experience has sanctioned,—whether by administering large, moderate, or very minute doses, or no doses at all; by helping the disease on in its normal course *(similia similibus)*, or by opposing its tendencies and progress (*contraria contrariis)* ;—by leaving it alone and watching *(expectant treatment)*, or by supporting the powers of life whilst the disease runs its natural course; —by depletion or transfusion;—by heat or cold;— outward applications or internal remedies;—by exercise or quiescence, excitement or repose, strong measures or mild;—by remedies which chime in with a theory, or with no theory;—in a word, medicine comprehends the useful application of *all* the truths, whatever their nature or bearing upon theory, which the experience of all time has established to be serviceable in the treatment of disease. Truth, wherever it is found, if it relates to healing, belongs to it. With homœopathy it has, and can have, no connexion whatever. Let the term "allopathy," then, be disused. If medicine stand in need of a special name to distinguish it from its spurious competitors, let it be spoken of as rational medicine, or eclectic medicine, or be styled by any name that shall not place it, in sound even, on the same level with the most subtle, extensive, and Hydra-headed species of charlatanism that ever existed.

As a fashionable flag, under which a practitioner may prescribe anything or nothing, provided he avoid effects too marked and immediate,—under which he may gain the credit due to nature, whether unaided or secretly aided by medicines in appreciable doses, without appearing to the patient to be responsible for future chronic disease originating in neglected active disorder, homœopathy will probably outlast many of the other forms of quackery. In all impostures upon the public, the greatest ever succeeds the best. But truth must, in the order of things, eventually prevail; indeed, in innumerable instances the duped have already seen the fallacy which misled them. And equally certain is the converse, that nothing but truth can ultimately maintain its ground. Consider how few of our own legitimate works on medicine have lived, or are destined to live, in comparison with the legion forgotten, or to be forgotten. The ephemeral book is a book more of opinions than facts. It may be true, but it contains not the proof of its truth. The book to live contains minute facts honestly observed, which once proved are true for ever.

We want more facts still, and fewer mere opinions; as much true theory as may be, so long as it is sufficiently substantiated by facts, and less of unsupported speculation. Even for the mere advancement of our profession, and with it of ourselves, above competition with quackery, truth must be our polar star. There is but one mode of attaining it,—by work. And do we not work; and have we not worked? Does any other profession work so hard for its daily bread? Does any other profession present so many energetic labourers, striving by night and day, for years unknown it may be, to gain an honourable scientific position? Is it not work for one labourer, for sixteen years, to note down constantly minute observations in auscultation, in order to distinguish physical signs as they are in nature, from physical signs as they have existed in the imagination? Is it not work for another to spend from four to eight hours a day, barring the time of certain illness from contracting fever, in minutely examining and noting down cases of continued fever, in order to decide, once for all, what are the facts concerning it, as it at present exists? Or, whether is it the easier—we will not ask, whether is it the more lucrative—to advertise capabilities as an aurist, or to dissect and examine minutely fifteen hundred organs of hearing, to distinguish the facts from the guesses concerning the pathology of the internal ear? Truly, no other profession furnishes so many individual hard workers.

The first thing which every member of the Association might do is, to avoid desecrating his noble science by the use of a false and undignified nickname.

Provincial Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 12, 1851.

We publish at a further page a letter from Dr. Robertson, late Assistant-Surgeon to the Military Lunatic Asylum at Yarmouth, which touches upon a subject of considerable importance to the interests of Military Medical Officers. We may be thought to take a very strange position, and shall doubtless earn for ourselves the indignation of every Martinet; but nevertheless, do not shrink from stating our opinion, that it would be far more conducive to the welfare of the service, if medical promotion were made to depend upon merit, and not mere seniority. The adherence of the present custom must, in the nature of things, be detrimental to the professional character of the Army Surgeon, as it leads him to be content with mediocrity of acquirements, for the plain reason, that the greatest superiority in knowledge, does not one whit advance his prospects; that, in fact, the most incompetent persons may, as opportunity offers, be, as a matter of course, placed over the head of the most talented and industrious officer if a few years his junior. This is the gravamen of Dr. Robertson's charge against

the Secretary-at-War; and a fair one it is, in our opinion.

Now, without reference to the particular circumstances of the case which calls forth these remarks, and which has caused the loss to the army medical service, of a gentleman distinguished for great general cultivation of mind, as well as by more than common professional merits, we here venture to advocate an entire change in the system which has hitherto regulated medical promotion in the army. We would not cavil at the manner in which advancement takes place among the fighting officers. To gallop at the head of a charge of cavalry, to lead forlorn hopes, and even to go through the more complicated evolutions, require but little intellectual eminence, and therefore promotion by date of commission is as good as any other, and far better indeed than the unjust system of purchase. But we submit that, in the discharge of the onerous and responsible duties of army surgeon, something more is requisite, and that the lives and limbs of our brave soldiers, depending as they do upon the scientific acquirements of those to whom they are committed, ought not to be placed under men, whose only claim is that of years, while others, it may be, of ten times their information and experience—for experience is not necessarily a matter of wrinkles and grey hairs—are left in a subordinate position. But if it be conceded that such a regulation is injurious, where surgical knowledge alone is necessary; the objection holds with increased force, when, as in the present instance, a speciality in professional experience is in question, and that speciality, moreover, involving the presumption of a form of information, which comparatively few army surgeons have the opportunity to acquire.

The treatment—medical and moral—of diseases of the mind, is always considered in the profession at large, as a duty of so responsible a nature as to necessitate a careful study directed to that particular subject; and, therefore, even in civil life, the care of lunatics is generally confided to persons who have devoted their attention specially to this melancholy affliction; how unseemly then is it, to use no harsher term, that the poor lunatic of the army, whose reason has perhaps been overthrown by the very circumstances of his perilous life, should be turned over as a matter of course, to a man who may have never witnessed, much less treated, a case of mental aberration; and this simply because he happens to have seen a certain number of years' service.

If there be one branch of professional practice, more than another, which requires special qualifications, it is this; and it is neither fair to the patient nor to the service, that those who possess these qualifications should be set aside, in order to comply with a regulation which, in this particular instance at least, would be more honoured in the breach than in the observance.

These observations are not the result of any personal feeling; the present superintendent of the Yarmouth Military Lunatic Asylum, we do not doubt, is well fitted for his duties, and so perchance may be the person who is destined to be Dr. ROBERTSON's successor; but we reiterate our conviction, that on general grounds, the Secretary at War would do well to contrive that such men as Dr. ROBERTSON be not lost to the service, from the feeling that their qualifications are not appreciated, and that the most diligent professional study does not give him the smallest advantage over the veriest dolt whose commission may date a few years earlier.

IN the recent movement against homœopathic follies and impostures, the agents have been the fully educated and practised medical practitioners; we are glad to find, however, that the *debutants* in legitimate medicine are equally determined to be free from the stain of quackery, and most properly look upon even the signature of a homœopath as a disgrace to their diploma. We cannot too highly commend the high spirit which dictated the following protest from the candidates for the M.D., at St. Andrew's.

"*To the Rector and Senatus Academicus, University of St. Andrew's.*

"We, the undersigned candidates for the degree of Doctor of Medicine in this University, having understood that our diploma will probably be signed by the Professor of Civil History, who is an avowed homœopathist, and holding as we do the opinion that the doctrines of Hahnemann are utterly irreconcileable with common sense, and with those medical tenets in which we have been educated, and which we trust will ever guide our professional career, respectfully request of the Senatus Academicus, that they will adopt such measures as they may deem expedient for the purpose of preventing that desecration of our diplomas which we consider would be inflicted upon them if a homœopathic signature were affixed thereto.

(Signed) "JOHN BROWN.
"JOHN COWIE.
"H. WATSON.
"EDWIN HUMBY."
&c. &c. &c.

This is indeed a noble set off against the unwitting grant of the diploma, under the disgraceful circumstances some time since alluded to, and shows unmistakably, that if St. Andrew's has unfortunately a homœopathic professor foisted upon her, she is alive to the dishonour, and will not falter in her endeavour to be relieved from its cause.

Reviews.

On Diseases of the Mucous Membrane of the Throat, and their Treatment by Topical Medication. By Wm. R. Wagstaffe, M.A., M.D. London: Churchill. 1851.

The intention of this little book is to exhibit the advantages of local treatment, in many diseases of the mucous membranes of the air passages, which are too often under the blister and ipecacuanha system allowed to subside into serious chronic affections. There is no originality in the methods proposed, the author having simply adopted the treatment by lunar caustic, first brought prominently before the profession by Dr. Horace Green, though previously employed, to a limited degree, by Bell and Trousseau. The diseases in which the author finds this treatment most efficacious, is in the relaxed and thickened condition, with hypertrophied follicles, of the mucous membrane, so often the result of repeated attacks of catarrh; also in hooping-cough and in croup. The solution used by Mr. Wagstaffe is one of argenti nitras, forty grains to the ounce, which is introduced to the glottis, and even through it, by means of an instrument devised by Dr. Green, consisting of a small piece of sponge attached to a whalebone handle. We can recommend a perusal of this book, from which some valuable hints may be extracted in reference to this particular mode of treatment.

The Prevention and Cure of many Chronic Diseases by Movements, &c. By M. Roth, M.D. London: Churchill. 1851.

Considering the amiable *empressement* with which every new mode of curing every disease is introduced into this highly-favoured country, it is really a wonder that there should be any necessity for bills of mortality; but some how or other, spite of the disinterested endeavours of the inventors and discoverers of new systems, death marches on much as usual. This is to be regretted. Here we have the "latest novelty of the season," as Messrs. Howell and James would say, and we will do it the justice to say, that in extent of promises it is no way behind its hydropathic, homœopathic, and mesmeric predecessors. Our readers, perhaps, may be somewhat at a loss to conceive how many diseases with which they are familiar are to be cured by movements, and would like to have a description of a method so opposite to what they have been accustomed. We will select a few for their inspection.

"*Acute œdema of the lungs, and incapability of expectorating.*—Put the patient in an upright position, shake his shoulders, knock his back, excite him to expectorate by screaming in his ear, and remove the mucus from the fauces by the finger."

"*Adhesions of the pleura* are treated by frictions in a straight line, on both sides of the chest, alternating with a vibration round the thorax, while the patient keeps his arms raised and fixed."—p. 215.

There is a little mesmerism in the process also; witness the treatment of—

"*Fainting:—Awakening passes** on the forehead, frictions of the limbs, horizontal position, passive raising of the arms above the head."—p. 217.

We poor benighted doctors find some difficulty in causing absorption of exudations into the pericardium. Here is the treatment of M. Roth:—

"The resorption in the pericardium is increased by very slight percussions with the palms of the hands, in different directions, on the side of the chest."—p. 217.

To cure gonorrhœa the prescription is:—

"Percussion on the sacrum, in the stride standing position. Transversal chopping on the neck in the sitting position. Pressure on the pubes in the lying position, with elevated back, while the separated and bent legs are drawn towards the abdomen; and, lastly, vibration of the perineum in the same position."

The above extracts will, we think, be sufficient to display the character of this extraordinary book. Had the author been content to enlarge in general terms upon the advantages of a well regulated system of gymnastics, in the invigora-

* The italics are ours.

tion of the frame, and the *prevention* of diseases arising from enfeebled and cachectic habits of body, instead of making a quackery of the thing, as he has done, he would have deserved the thanks of the profession; but when he tells, in seriousness, that the diseases we have mentioned are to be cured by the harlequinades he describes, he lays himself open to just ridicule, and what is worse, throws a stumblingblock in the way of his readers, which may chance to prevent their appreciating the very infinitesimal portion of what is really useful in his book.

Talking of "infinitesimals," we may also state, that when Dr. Roth condescends to resort to medicine, homœopathy is his chosen handmaid. In this he is wise, for if any discussion should arise as to the respective merits of the two "pathies," then it would be difficult to determine which is the most ridiculous. We should, however, in that respect, decidedly give the palm to homœopathy.

Proceedings of Societies.

MIDLAND DISTRICT BRANCH.

Report of the proceedings at a meeting of medical practitioners held at the Town Hall, Derby, November 6th, 1851, for the purpose of establishing a Midland District Branch of the Provincial Medical and Surgical Association.

SIR CHARLES HASTINGS, M.D., IN THE CHAIR.

Present:—Dr. Williams, Nottingham; Dr. Bent, Dr. Heygate, Dr. Goode, Dr. Johnson; Messrs. D. Fox, W. Johnson, Fearn, Gisborne, Greaves, Evans, Jones, Borough, C. Harwood, Bell, Boden, Walker, Tasker, Stone, Hollis, Darby, Norman, Cope, Willis, Mason, Walker, and Cantrell.

The President, in an opening address of some length, explained the general objects of the Association, and with much eloquence and force dilated upon the advantages which have been found to accrue from the establishment of District Branches; after which it was

Moved by Dr. Williams, of Nottingham, and seconded by Mr. Cantrill, of Wirksworth,—

"That it is the opinion of this meeting that it is desirable to form a Branch of the Provincial Medical and Surgical Association, to be called the *Midland Branch*."

Moved by Dr. Heygate, F.R.S., and seconded by Mr. Douglas Fox, Mayor of the Borough,—

"That Dr. Bent be, and he is, hereby appointed the first President of the Midland District Branch of the Provincial Medical and Surgical Association."

Proposed by Mr. Gisborne, seconded by Mr. Tasker,—

"That Mr. Fearn be, and he is, hereby appointed Honorary Secretary of the Midland Branch."

After a discussion, in which it was deemed desirable that the Counties of Nottingham, Leicester, and Lincoln, should be included in the Midland District Branch, it was

Moved by Mr. Jones, and seconded by Dr. Goode,—

"That a Committee of three members for each of the county towns be this day formed, to draw up the laws of the District Branch, and to transmit them to the Central Council of the Association at Worcester for confirmation; and that a general meeting of members be held at Derby the first week in December, to receive the report of the Committee, to elect the officers and Council for the ensuing year, and to receive such medical and surgical communications as members may be disposed to contribute. The Committee are also requested to consider whether a Secretary and Council should not be appointed in each town to manage the affairs of the District Branch. That Dr. Bent, the President, and Mr. Fearn, Secretary, be *ex-officio* members of the Committee. That the following be also members of the Committee:—

Derby.—Dr. Heygate, Mr. Douglas Fox, and Mr. Gisborne.

Nottingham.—Dr. Williams, Dr. Hutchinson, and Mr. Darby.

Leicester.—Dr. Shaw, Mr. Paget.

Lincoln.—Dr. Charlesworth.

That the Committee be requested to communicate with the profession in Leicester and Lincoln, to ascertain whether they are willing to join the District Branch, and also to fill up the vacancies in the Committee."

Proposed by Mr. Fearn, seconded by Mr. Willis,—

"That a circular embodying the resolutions of the meeting be sent to every member of the profession in the four counties included in the Branch Association."

A letter was then read by Dr. Heygate from Dr. Hitchman, of the Derby County Lunatic Asylum, expressing his regret that he was unable to attend the meeting, and kindly offering to read a paper "On Epilepsy" at the first meeting of the District Branch.

A vote of thanks to Sir Charles Hastings for his able and courteous conduct in the chair, having been proposed by His Worship the Mayor, and carried by acclamation, and Sir Charles having responded in an eloquent and feeling address, the greater part of the meeting adjourned to the Royal Hotel, where an excellent ordinary had been prepared for them.

About twenty new members of the Association were enrolled at the meeting.

BATH AND BRISTOL BRANCH.

The Quarterly Meeting of the Bath and Bristol Branch Association was held at the York House, Bath, on the 2nd of October, 1851, under the Presidency of Dr. Symonds.

There were present,—Dr. W. Budd, Dr. W. C. Fox, and Messrs. Colthurst, and Lancaster, of Bristol; Dr. Burne, Dr. W. Davies, Dr. M'Dermot, Dr. Tunstall, Messrs. Barrett, Brace, Church, Cox, Evans, Godfrey, Kilvert, King, Mason, Norman, Sheate, Soden, and Stone, of Bath; Dr. Woodforde, of Taunton; Mr. Vicary, of Warminster; Mr. Edwards, of Batheaston.

The minutes of the last meeting having been sanctioned,

Dr. Burne read a history of a "Case of Mumps, complicated with Nephritis, Albuminuria, &c." [Published at page 623.]

Dr. Woodforde then brought before the meeting a "Case of Peculiar Disease of the Tongue, in which the Sense of Taste was wholly destroyed." [This paper will be published in a future number of the *Journal*.]

Dr. Budd detailed the history of a "Case of Abscess of the Cerebellum, originating in caries of the Petrous Bone." [Published at page 621.] He observed that many similar cases had been published, notwithstanding which it was advantageous that well-marked and carefully observed cases, though isolated, should be reported. The interest of the case was chiefly physiological, interfering as it did so materially with Fleurens' deductions from experiments, that there exist co-ordinate powers between the opposite side of the cerebellum and muscular power. Dr. Budd called especial attention to the several amendments and apparent cure, and then quoted Rokitansky's opinion on the possibility and mode of cure. The disease originating in the petrous bone and in the internal ear, and not the external, militates against Toynbee's experience, that disease of the external ear induces disease in the cerebellum, while disease of the internal ear leads to disease of the cerebrum.

Mr. Norman mentioned two cases that had come under his notice where disease of the internal ear had been followed by abscess in the middle lobe of the cerebrum, in neither of which had there been any pain or other symptoms until immediately preceding death. In one of the cases the abscess burst into the ventricle.

Mr. Barrett mentioned the case of a child in whom there was hernia cerebri, and in whom a large abscess took place in the brain, without its progress being marked by any symptoms. Mr. Barrett mentioned this case as an example of the tolerance of the brain to gradual external pressure.

Dr. Burne observed on the peculiarity of the case detailed by Dr. Budd, inasmuch as the membrana tympani remained entire, and inquired of Dr. Budd how he considered the abscess of the cerebellum to have arisen.

Dr. Budd replied that he considered the case as an example of purulent poisoning by means of the blood-vessels, and not as one proceeding from contiguity of position, and referred Dr. Burne to some cases of the same kind, mentioned by Dr. Watson in the third edition of his lectures.

Dr. Tunstall instanced a case that had come under his notice, where great tolerance of internal pressure of the brain had been shewn, the pressure having been gradual.

Dr. Symonds recalled the attention of the meeting to the physiological bearing of the case, with reference to the presumed functions of the cerebellum, namely, the co-ordination of muscular movements, and the maintenance of equilibrium He thought the explanation of such cases as that detailed by Dr. Budd, was to be sought for in their chronic character, that the changes were very gradually produced, and that hence time was allowed for the compensating power of duality to come into operation.

THE BRISTOL ROYAL INFIRMARY MEDICAL SOCIETY.

Session 1851-2.

INTRODUCTORY MEETING.

The President (H. A. Hore, Esq., House-Surgeon), on taking the chair, said that it was extremely gratifying to him to find the high estimation in which the Society was held amongst students. A work undertaken with truly sincere motives was sure to succeed, and they had the satisfaction of finding that the little differences which existed in the minds of a very few students towards their Society had almost entirely subsided. A slight difficulty had arisen with some of the junior members, who entertained an idea that they were too inexperienced to gain any advantage from the discussions. This might be to a certain extent correct, but they must remember that, in order to derive benefit from them when they become more advanced in knowledge, they must undergo the apparent irksomeness, for a time, of listening to what they might not altogether understand; but by reading of the subjects which were brought under discussion, they would soon find that they would become interested in the proceedings and able to take part in the debates.

During the recess the Council had given much attention to the subject of medical ethics in connection with the Society, and especially with regard to homœopathy; as they were, however, convinced that as yet no such heresies existed amongst their members, they at present refrained from passing any resolution or law on the subject, but were individually determined to resist to the utmost the admission into the Society of any gentleman who might be guilty of any unprofessional conduct. He would not detain them further, but would introduce to them Mr. Harrison, the senior-surgeon of the Bristol Royal Infirmary, who had kindly promised to deliver an Introductory Address on the present occasion.

Mr. Harrison commenced his address by stating, that as the advantage of literary and scientific societies was such a hacknied subject, he hoped the meeting would grant him their indulgence if he should be found to exceed the boundary of the theme usually assigned upon an occasion like the present.

The society had last year been congratulated by Dr. Wallis on the right good spirit evinced at its formation, and he was now, having been cognizant of its operations

during the last session, in a position to state that the promises then held out had been amply redeemed, and that the members had advanced with great zeal and ability upon the wide field of medical and surgical research they had thus opened for themselves. He would congratulate them on establishing a Society so useful in advancing their professional interests, and which had been regarded by his colleagues generally, as well as by many other members of the profession in their city with very great pleasure and interest; established by the spontaneous exertions of their own circle, they had set up for themselves a very important element of education. The Society was founded by the *students* of the Bristol Royal Infirmary. It was fresh and vigorous in its existence, for the Society was youthful both in its existence and members. Fresh and vigorous might it ever be. Laudable ambition, and a spirit of emulation and liberality, arising from social intercourse in matters of science, would ever form, he trusted, its distinguishing attributes.

Pages had been written upon the happiness, contentment, and profit gained by the acquisition of sound knowledge; and there was certainly a proud nobility in the possession of knowledge. He remembered an anecdote of the great composer, Beethoven, who, having been visited by a pompous friend who, on his card, announced himself as "Landowner," returned the visit by leaving his card, inscribed "Ludwig Von Beethoven, *Brainowner*." Yes, though they might not bear the coronet, yet the title of brainowner was open to all, and one which no earthly power could deprive them of.

Much had been said and written upon the philosophy of medical study, and at an introductory meeting of a discussion society, it might be expected that he should enter somewhat into the subject. The Society he was addressing had its peculiar advantages. Its discussions were held in a vast museum of living morbid specimens. Day after day its members were in the habit of passing in review, almost all the varieties of disease or injury to which the human body was liable; from such ample materials they selected their subjects for notes, inquiry, and subsequent discussion. He knew of no better mode of acquiring diagnostic readiness and practical knowledge than these opportunities afforded. His advice would be brief and earnest. Get face to face with disease as much as possible. Let patience, perseverance, and humility, be the watchwords; make the best use of the present opportunities, not forgetting what was said of time and tide.

"Labitur et labetur in omne volubilis ævum." With such care, homœopathy, mesmerism, and all the other quackeries of the day were not at all likely to endanger the sensible student, who would only regard these fallacies with a painful and humiliating sense of the weakness of human nature. It was curious to observe how charlatanism, based upon credulity and knavery, had flourished in all times and societies; a many-headed Hydra—it was ever starting up under different names, and was always certain to enlist numerous votaries from amongst the weak and imaginative. They might trace the system from the stamped box of pills through the various phases of folly and superstition, which were really the disgrace of the enlightened era of the 19th century. How extraordinary it was, that in these times of practical skill and enlarged views of science and art, the mesmerizer should claim, and be allowed by his followers, the powers of Omniscience and Omnipresence; for upon an analysis of the mesmeric creed, its demands upon credulity would be found to be nothing less. Homœopathy claimed not those attributes, but demanded almost as great a concession upon the part of the credulity of the public. He had witnessed some distressing results from the practice of this ephemeral folly, which, under a smiling and seemingly innocent front, concealed the deadly sin of omission, and allowed the precious moments for active treatment during the progress of acute disease to pass unheeded. This was a gloomy picture, but they had the consolation of knowing that those pretenders who hovered about the paths of true medical science, like birds of dark and evil omen, could effect nothing permanently to obscure the bright and holy way of truth. She advanced based on broad and simple facts, hand in hand with progressive knowledge and civilization, whilst the delusive shadows of error vanished like the morning mist before the bright sunshine of her presence. It must, therefore, be the earnest care of the practitioner to avoid all that deception and self-laudation which would ally his profession to that charlatanism which he had now been deprecating. He should aim to influence his patients by the honesty and open rectitude of his conduct, remembering, at the same time, their peculiar susceptibility to be impressed with whatever falls from the lips of their medical attendant.

The Society whose interests he was that night advocating, might be taken as an index of educational improvement. He knew that student societies of the same character were established in connexion with the leading hospitals in London, but he was not aware that they had yet been founded in the provinces, and he believed that Bristol had taken the lead in thus setting up her Student Medical Society. There was no doubt that medical debating societies were not only serviceable to the members actually engaged in the debate, but that they also exercised a very useful influence in promoting the general advance of medicine and surgery. How much more simple and philosophical was the treatment of cases after operation, both in the modes of dressing and the treatment. Chloroform might also be regarded as one of the greatest improvements of modern times, setting aside the inestimable privilege of suspending pain, the patient's perfect repose and freedom from struggling, when under the influence of this remarkable agent, were productive of the greatest advantage to the surgeon, who performs his operations with increased safety and celerity. He could not, while on the pleasing subject of the improved surgical knowledge of the present day, pass by the important case they had lately witnessed in the wards. He alluded to the operation for the removal of an artificial anus by means of Dupuytren's instrument, terminating in the complete recovery of the patient from one of

the most distressing maladies that afflict the human race, thus being an instance of the triumph of modern art resulting from the exercise of thought and study.

He felt that in the pleasure of advocating their debating society he must not forget to dwell for a moment on the Bristol Royal Infirmary, that *alma mater* from whom the society sprung. She was, it was true, an ancient mother, but she bore her old age greenly, the most venerable as well as the largest of all the provincial hospitals of England, she feared not comparison with her sisters of more modern times. How many students had gone out from beneath her old portal to enter upon the cares and anxieties of a professional life! Might there not be one for the future who would be obliged to look back and experience the bitter feeling of regret for time misspent, opportunities lost, never to be recalled.

Statistics of public hospitals were most important and valuable documents, and he deeply regretted that for upwards of 100 years they had no minute records of the vast amount of cases received into the wards. Latterly, he was happy to say, this great want had been supplied by their excellent house-surgeon, Mr. Hore, the President of their Society, to whom the honour was due of being the first of the house-surgeons to publish an annual statistical account of the cases; this continued diligently from year to year would afford most valuable matter for comparison and inquiry. He had not yet alluded to the annual prizes of the Society; he would sincerely congratulate the successful candidates, and hoped the Society would permit him to make an addition to their prize-fund for the ensuing session.* Years quickly rolled by, and they would soon be in practice for themselves, and he hoped they would be able to look back with pride and satisfaction upon the old house, and the pleasant and instructive meetings of the Student Medical Society held within its walls. He trusted that the valuable lessons of the former might not be forgotten, and that the good spirit which they knew to be the attribute of the latter might continue to animate them in their professional progress through that great debating society—human life, in whose wide arena the professor of knowledge, the ready and apt observer, and, above all, the earnest supporter of whatever was honest and true, would always take an honourable and an honoured place.

Votes of thanks were then passed to Mr. Harrison for his able and interesting address, and for the kind donation he had presented to the Society, also to the physicians and surgeons of the infirmary for the kind and continued interest they took in the affairs of the Society.

The President then proceeded to distribute the prizes to the successful candidates. The Essay Prize to Mr. C. F. Maunder, and the Discussion Prize to Mr. Henry H. Cox.

These gentlemen briefly refurned thanks, after which the President dissolved the meeting.

W. GARRARD, E. H. SWETE, } Hon. Secs.

* This donation of £5 was afterwards determined to be given as a prise in books or instruments for the best reports of not less than thirty cases occurring in the wards of the Bristol Royal Infirmary, from November, 1851, to September, 1852.

EAST KENT AND CANTERBURY MEDICAL SOCIETY.

The above Society was formed in 1849, by members of the medical profession residing in Canterbury and the eastern division of Kent, for the purpose of circulating medical books, establishing a permanent library, and collecting a museum. The library and museum are placed at the County Hospital, where the meetings of the Society are held. With the view of obtaining the co-operation of two medical Book-Societies, previously existing in the same district, this Society agreed to associate itself with them, under certain conditions by which each should annually contribute to the library a fixed proportion of the books that have returned from circulation. By such contributions every member of the united Societies is entitled to all the privileges connected with the library. One of these Societies has favourably received the proposition, and is united with the East Kent and Canterbury Society for the above object. A joint Committee manages the affairs of the library, which at present contains 826 volumes. For the purpose of collecting materials for forming a museum, the Society holds meetings to receive pathological specimens, and to relate and discuss cases connected with them, as well as on medical subjects generally. The museum at present contains upwards of 140 specimens, though the development of this object of the Society has been in operation only twelve months.

Session 1850-51.—First Meeting, Oct. 9, 1851.

Pathological specimens relating to the following cases were exhibited:—

Uterine Phlebitis.—By Mr. A. B. Andrews.

Mrs. F., aged 38, was delivered September 1, 1851, by a midwife, of a child presenting with the breech. The placenta was retained for two or three hours, when hæmorrhage occurring to an alarming extent, Mr. T. Andrews was sent for, who introduced his hand and with considerable difficulty detached the placenta. The patient was very much blanched and reduced by the bleeding. Some oozing of blood continued after the removal of the placenta, but the amount thus lost was not great. The discharge from the vagina, which was at first copious, soon became scanty and very offensive. In three or four days after delivery, Mr. Andrews was again summoned to the patient, who had not been regularly placed under his care, and found her in a very reduced state, suffering from severe diarrhœa; with proper treatment the diarrhœa improved, but on the 10th reappeared, when the pulse was very feeble and quick; the abdomen, though not distended, was very tender in the situation of the uterus; she became worse and died on the 12th.

Post-mortem examination twelve hours after death.—There were no evidences of general peritoneal inflammation; the left uterine appendages were red and enlarged, as well as the veins proceeding from them, for

some distance; the interior of the uterus was rough and uneven, and was irregularly covered with lymph; no pus was detected in the uterine tissue, though the veins were large and patulous; the left spermatic veins were much enlarged, and their coats considerably thickened; they were plugged at intervals with deposits of lymph, the intervening spaces being filled with a dirty-looking purulent fluid.

Multilocular Cyst removed from the Thigh.—By Mr. James Reid.

Mr. L., a tall, strong, and active farmer, 48 years of age, fell from his horse in December, 1839, and bruised himself about the right trochanter. The injury did not confine him to the house, though he was inconvenienced for some days, and leeches were applied by his medical attendant. Shortly after this he perceived a lump in the situation of the injury, but as it did not trouble him, he took no particular notice of it, nor thought much about it. The swelling, however, in the course of nine years and a half, had slowly increased, but was still small. It then began to enlarge rapidly, and the attention of his medical adviser was directed to it. A large fluctuating swelling was found on the outer side of the thigh, which became so much distended that, on November, 19th, 1842, it was punctured by a trocar, and rather less than a quart of serous fluid, stained with blood that had mixed with it in the cyst, was evacuated. The emptied cyst formed a deep depression in the limb, with a considerable firm consolidation of parts around, especially towards the lower part. The cyst slowly refilled, and was emptied of its contents, which had the same appearance, on December 27th, and January 17th, 1850. Mr. Reid saw the patient, in consultation, on January 24th. The cyst had filled again, and was about the size of a Dutch cheese, but somewhat ovoid in form, the long axis extending from above, downwards, and forwards. It was placed on the upper and outer part of the limb, principally in front of the trochanter, which, however, it concealed, together with the upper part of the femur. Several large veins passed over the surfaces, and at the upper and outer part the integument covering it was so very thin that it threatened to ulcerate very soon. Its base was firmly attached, but did not apparently extend deeply. The patient had suffered very little pain, and was principally inconvenienced by its size and situation. The swelling was tapped again, and about the same quantity issued as before; the fluid was the colour of treacle, and was much darker than that which had been evacuated on the former occasions.

January 31st.—Mr. R. removed the tumour. A large surface was exposed in dissecting it out. The base was so intimately connected with the fascia beneath, that it was necessary to remove rather a large portion, together with part of the tensor vaginæ femoris. The patient had a good recovery. The cyst adhered very firmly to the surrounding textures. The adipose tissue, which was abundant, was with difficulty dissected from the growth. It was found to consist of two compartments,—a larger, which was situated lowest upon the thigh, and a smaller or upper one, which appeared to be a development from the larger. A narrow constriction separated the two compartments. The wall of the cyst was a firm tough structure, rather more than the eighth of an inch thick. The internal surface had a light-brownish or chocolate colour, the shade varying in different parts; it was soft and vascular, presenting some minute irregularities, with a few larger bodies projecting from the surface, having the appearance and consistence of lymph; there were also several openings communicating with secondary cysts. The fluid contained in the cyst had the appearance of venous blood, mixed with some dirty liquid. The colour of the surface, which could be partly wiped off, seemed in some measure due to the contents. The larger division also contained a loose mass of dirty-brown fibrin as large as a walnut. In the walls of the cyst, but more particularly in the smaller compartment, the external surface of which was very irregular and nodulated, there were numerous smaller cysts in various stages of development. They apparently commenced in small bodies, of a fawn colour and soft consistence, the exterior of which became firmer as they enlarged, the contents at the same time softening, and being found in the smaller ones of the consistence of soft fibrin, and in the larger of that of thick gruel. These secondary growths, as they became developed, communicated with the parent cyst, their contents escaping into it. One of the largest of these was found thus partly emptied of its contents, which being of a grey colour, contrasted with the liquid in the large cyst.

Cystic Disease of the Testicle.—By Mr. James Reid.

E.B., aged 26, of short stature and fair complexion, with red hair, was admitted into the Kent and Canterbury hospital, June 14, 1850. About seven months since he perceived that the left testicle was beginning to swell without any apparent cause. He remembers that, previously, whilst using the axe at his work as a carpenter, he several times struck the testicle with the handle so as to cause pain for half an hour. He never had gonorrhœa or syphilis, and has always enjoyed good health. The swelling slowly increased, and for the last two months he has experienced a dull aching pain, particularly towards evening, extending to the loins and down the thigh; there has also been sometimes a fixed pain at the crest of the ilium. The left testicle is about the size, and has somewhat the form of a large Windsor pear, the broad end being dependent, and a deep depression separating it from the upper, which is so soft as almost to convey a sense of fluctuation. The whole mass is heavy, soft, and elastic, and distinctly fluctuates in front. When examined with the candle, light is not transmitted, though there is some difficulty at first in positively deciding this point. The cord is unaffected, and by deep pressure in the iliac region no enlarged glands can be detected. That the disease was neither syphilitic or strumous, seemed clear from the history of the case, and the character of the swelling; but evidence as to its not being hydrocele nor hæmatocele was thought

insufficient. The tumour was, therefore, punctured with a small exploring needle and trocar, when half an ounce of straw-coloured fluid escaped from the tunica vaginalis, and upon thrusting the trocar deeper, a small quantity of glairy fluid, resembling white of egg, issued. It was now evident that the enlargement was not hydrocele, nor hæmatocele, but probably disease of a malignant kind. The only remedy that appeared under the circumstances likely to be useful, namely—iodine, was used internally and externally; but it was not until the 5th of September that the patient was fully under its influence; the swelling, in the meantime, had slowly increased. The testicle was removed on the 12th of September; eight vessels required to be secured at the time of the operation, and four more two hours afterwards. The wound healed slowly, principally by granulation. The testicle was examined immediately after its removal. The tunica vaginalis contained a small quantity of fluid, and was slightly adherent by recently-effused lymph, which was principally deposited in the neighbourhood of the epididymis. The tunica albuginea was entire, but tightly stretched, for it gaped very widely when divided. A section showed that the tumour was composed of a mass of closely compacted cysts, varying in size from that of a pea to a mustard seed. They were for the most part so thin and transparent, that the interior could be seen through their walls; they contained a clear glutinous fluid. Some of the larger cysts communicated with others, and at the upper part of the tumour there was a cavity capable of containing a bean, that had been formed by the communication of several cysts, and contained pus, mixed with the fluid; in one or two of the neighbouring cells a drop of pus was found, surrounded by glairy fluid. On the walls of several of the cysts a small yellowish body was noticed, which appeared, when pricked, to be a small cell. There was little or no tissue interposed between the cysts, but the whole mass was enveloped by a condensed layer, forming a sort of capsule; many small vessels were noticed ramifying around the cyst. The seminal ducts were spread out in a thick layer that surrounded the growth.

Foreign Department.

GERMANY.

On the Treatment of Ophthalmia Neanatorum.—By Dr. Binswanger.

The following treatment (*Neue Medicinische Chirurgische Zeitung*) has been found, after long trial in the Hospital of Munich, to be quite worthy of confidence:—

In the non-specific form a cure is often accomplished by simple cold injections and fomentations. The more obstinate cases generally yield to the injection of a weak solution of sulphate of zinc; leeches and scarifications are in general not required.

In the form arising from leucorrhœa, the general plan is, to make a few superficial scarifications of the conjunctival mucous membrane. A zinc collyrium is then used, and the cure is completed by the use of an ointment of white precipitate.

In the specific form produced by gonorrhœa, scarifications are more necessary, and the zinc collyrium is replaced by one of nitrate of silver.

The great advantages of cold water injections is strongly insisted upon in an article in *Schmidt's Jahrbücher*.

Spasmus Nutans.

The disease which has been noticed by our associate, Mr. Newnham, in this journal, under the name of eclampsia nutans, or "Salaam convulsions," has not escaped the attention of German writers. In the *Journal für Kinderkrankheiten*, Dr. Fober has narrated two cases. The first was that of a little girl, aged three years, who, after losing flesh gradually, since the commencement of dentition, began to complain of headache; she was drowsy, and had occasional strabismus. At intervals she nodded her head to the left side, during periods of several minutes duration. These attacks increased in frequency and intensity, and at length became positively frightful from their violence. All treatment has proved ineffectual; the child gradually became more dull, and has now, on waking from sleep, general convulsions of an epileptic character. She is idiotic in appearance.

The second example, a boy aged 6 years, fell by accident into a well; the result of which was that he was confined to bed with a slight cold. It was noticed, however, that from this time he was an altered child, and he frequently awoke suddenly, screaming. The nodding movements commenced accidentally on being severely reprimanded by his father, and from this time gradually became more severe, till the nodding reached the number of 80 in the minute. They still go on in spite of treatment, at intervals of a few hours, and the child evidently loses flesh.

Action of Medicines on the Spleen.

Many physicians, and chiefly M. Piorry, regard enlargement of the spleen as the characteristic lesion in intermittents. If such be the case, the increase and diminution of this organ under medicinal agency is worthy of serious attention.

M. Piorry, (*Union Médicale*, 1851) has observed that the spleen rapidly diminishes in volume under the use of common salt in large doses. He has employed it in nine cases of intermittent fever, and professes to have cured six of them. He also states that he has in the same way reduced the volume of the spleen in typhus.

Dr. Keichenmeister (*Archiv. für Phys. Heilkund*, 1851), has made several experiments on the subject on the lower animals, the results of which he details. From these it appears, that in pigs, which for some reason were the only animals suitable for the experiment, the spleen always became shrivelled after the exhibition of quinine. The organ was exposed to view. He also ascertained that next to quinine, the active principle of

gentian—*gentianine*—had the most powerful effect on the spleen.

On the Estimation of the Amount of Globules and Plasma in a given quantity of Blood.

Zimmerman (*Schmidt's Jahr.* and *Edin. Journ.*) professes to have arrived at a satisfactory method of estimating the proportions of the above elements of the blood. He assumes that nitrate of baryta, while it prevents coagulation of the blood, does not pass into the blood cells. He has chosen nitrate of baryta, both because the blood contains no salt of baryta, and because the addition of nitric acid does not interfere with the quantitative determination of the blood salts. He mixes a weighed portion of blood with a certain proportion of solution of nitrate of baryta, of known strength. When the blood-cells have subsided, he determines the amount of solids contained in the serum and cruor, and hence calculates the solid contents of the whole blood by subtracting the weight of baryta salt which has been mixed. He also determines the amount of nitrate of baryta in the serum, and finds by subtracting this from the previously ascertained total serous solids, the amount of the true dried constituents of the plasma. Then he finds the amount of nitrate of baryta in the cruor, and how many parts of serum this corresponds to. Finally, by subtracting this proportion of serum from the cruor, he determines the weight of the solids of the blood-corpuscles. If from another portion of blood the amount of fibrin has been determined, it is easily to calculate the per centage of the different blood constituents in 1000 parts. If the proportions be sought by estimating the amount of chlorine in the serum and cruor, according to the assumption of Berzelius, that the blood cells contain no chloride of sodium, a smaller amount of blood-cells containing more solids than water is obtained. Hence he concludes that the blood-corpuscles do contain chloride of sodium, and that his method of estimating their amount is the more exact. As proofs that the blood-corpuscles absorb no nitrate of baryta, he adds :— 1. That the blood-corpuscle will not take up every salt. 2. That baryta is an element quite strange to the blood-cells, and hence unfit to enter them. 3. That the salts of the blood-cells would immediately form insoluble compounds with baryta.

General Retrospect.

PRACTICAL MEDICINE.

Cauterization of the Larynx in Hooping Cough.—By Dr. Eben Watson.

The author considers the true pathology of hooping cough to be, that it is the product of a poison which exerts its first influence on the mucous lining of the pharynx and larynx, and on the sentient nerves, viz., branches of the superior laryngeal, supplying these parts; and that, in the next place, the inferior laryngeal becomes excited, and partial spasm of the glottis follows. With these views it occurred to him to extend to this disease the treatment first introduced by Dr. Horace Green, namely, the touching the pharynx, and even the interior of the larynx, with a solution of nitrate of silver, by means of a sponge attached to whalebone. He therefore gave up the usual treatment, and merely confined the patients to the house, applying the caustic solution every other day. The result was, the cessation of the disease in an unusually short space of time. The strength of the solution is from one to two scruples to the ounce of water. In cases attended with complications, the accredited treatment of these must be carried on conjointly.—*Lancet*, Oct. 18, 1851.

Colchicum in the Cerebral Complications of Scarlatina.

Dr. Hughes Bennett mentions the case of a boy, aged 14, the subject of scarlatina. He was delirious, and constantly rolled the head from side to side. He was conscious when spoken to; the tongue was protruded with difficulty, dry, red, and studded with fluid elevations; bowels open; pulse 130, weak; urine scanty, not acted upon by heat and acid; eruption full and bright. He was ordered diuretics and salines. He continued in the same state, with delirium and coma, till the sixth day. He was now ordered—

Vin. Colchici, oz. ss.; Sp. Æth. Nitrici, dr. iij.; Potass. Acetat., dr. ij.; Aquæ, oz. iij.

Dose.—A teaspoonful every four hours.

On the following day all coma and delirium had disappeared; the pulse fell to 96; the urine increased in quantity, and was loaded with sediment consisting of membranous flakes and urate of ammonia. From this time the boy did well.

Dr. Bennett states, that he regarded the cerebral affection as depending on insufficient elimination of urea; and remembering the alleged influence of colchicum over this secretion, he gave it in combination with diuretics. The result was so speedy, that the question may naturally be asked,—Whether the benefit was not due to a spontaneous crisis?—*Edinburgh Monthly Journal*, August, 1851.

Diagnosis of the Special Causes of Cyanosis.—By Dr. Chevers.

Dr. Chevers observes, that it is impossible to diagnose the lesions of the vascular system of an infant a few days old; still, if a child becomes cyanosed almost immediately after the establishment of respiration, it most probably arises from closure of the pulmonary orifice, with imperfection of the septum ventriculorum.

Where the symptoms of morbus cæruleus are not developed until some days or weeks subsequently to birth, it is probable that the orifice of the pulmonary artery is narrow, the ventricular septum open, and the foramen ovale and arterial duct either closed or distinctly contracted; or the latter of these passages may have become narrowed or closed, while the former is widely pervious.

If the infant be upwards of a year old, it is in the last degree improbable that it suffers from the malformation usually known as "distribution of the descending aorta from the pulmonary artery."

If the child has survived its fourth year, transposition of the great arteries is scarcely to be suspected.

When cyanosis is present at about the age of three or four years, it is probably due either to the great contraction, or closure of the pulmonary orifice, with ventricular communication. Should a single systolic bruit be heard superficially in the region of the pulmonary orifice, the case will almost certainly prove to be one of the former kind.

At the age of one month, or at any subsequent period, it cannot be judged with any probability that the heart literally consists of only two cavities.

In early infancy there are no means of diagnosticating between imperforation of the pulmonary artery and transposition of the two main arteries, except that the former irregularity is of far more frequent occurrence than the latter.

If the patient be above the age of seventeen years, imperforation of the pulmonary orifice can scarcely be suspected.

A person above the age of sixteen years, or a young adult, suffering from cyanosis of long standing, a bruit being audible in the region of the pulmonary artery, most probably has contraction of the orifice of that vessel, with perforation of the septum ventriculare.

If the individual has passed the period of early youth before becoming the subject of cyanosis; or if that symptom, formerly scarcely perceptible, has become considerably more apparent of late, it is, at first sight, probable that the disease is congenital narrowing of the pulmonary artery, the impediment having latterly been increased by thickening and further contraction of the parts, consequent upon superadded disease. In this case the ventricles probably do not communicate.

If the patient has passed the age of thirty years, the existence of congenital deficiency of the ventricular septum is highly improbable. Those who suffer from a congenital cause of obstruction which has originally been sufficient to arrest the development of the septum, very rarely, if ever, attain so advanced an age.

If, in any given case of cyanosis, the symptoms be ascribed solely to a patent condition of the foramen ovale, the incorrectness of that diagnosis will certainly admit of proof upon examination of the body.—*Medical Gazette.*

SURGERY.

Operation to remedy Extraversio Vesicæ.—By Mr. Lloyd.

The patient who is at present under treatment, is a healthy looking man, aged 30, At the lower part of the abdomen, between the umbilicus and the pubes, there is an opening readily admitting two or three fingers, surrounded by a red granulating border. Above this, the integument is raised by a prominent elastic tumour, which is the fundus of the bladder. From the opening here described, the urine escapes and excoriates the adjacent parts of the abdomen and the thighs. The penis is short and imperfect along the upper surface, where it forms a groove or canal. It is incapable of perfect erection. The prostate gland exists; the two lateral lobes can be felt from the rectum but the organ is smaller than natural. The scrotum is complete, and the testicles have descended from the abdomen.

The patient closed the opening in the abdomen by a large pad, fixed by a bandage round the small of the back. It answered its end in part; but the escape of urine soaked through the clothes, and rendered him, from the unpleasant odour, unfit to be in the society of others.

Mr. Lloyd proposed to the patient the operation of puncturing the bladder from the rectum, above the prostate, and establishing a recto-vesical fistula. The passage of urine through the rectum being complete, he then had in view the closure of the opening in the front of the abdomen by paring the edges with a sharp knife, and uniting them by suture.

The patient having been rendered insensible, and secured as in the operation of lithotomy, a long trocar armed with some threads was passed through the posterior wall of the bladder from the rectum. The seton having been detached, the instrument was withdrawn; but the two ends of the seton, one projecting from the rectum, and the other from the vesical cavity in the abdomen, were tied in a knot. The patient was then put to bed. The operation lasted no time, nor were there any difficulties to be encountered worthy of note. The result of the case is, of course, uncertain. The further progress, together with the effect of the passage of urine into the cavity of the rectum, will be the subject of a future report.

In this case, the anæsthetic agent employed was a drachm of chloroform to two ounces of sulphuric ether. The fluid was poured into a large bladder, to which an ordinary mouth-piece was attached. The patient, therefore, breathed into the bladder. Both the instrument and the fluid answered its purpose. Insensibility was produced in the usual time, and maintained without trouble.

[This patient died on the fifth day after the operation, from peritonitis, from extravasation of urine into the peritoneal cavity. The puncture had passed through the recto-vesical pouch, which descended deeper than usual, instead of before it, as was intended.]—*Medical Times*, October 11, 1851.

MIDWIFERY AND DISEASES OF CHILDREN.

On the Duration of Pregnancy.—By Dr. Murphy.

Dr. Murphy has recently read a very interesting paper on a subject of great interest, both in a physiological and medico-legal point of view. Two questions are proposed by him for elucidation:—First,—Is the duration of pregnancy a fixed or a variable period? and, if it be decided that it is variable,—What are the limits of its variation? He stated that the usual mode of calculating the term of pregnancy is by dating from the last period of the menses to the time of delivery, the gross results being corrected by deducting as many days as is supposed necessary to avoid error. Some, believing that conception may take place at any time, deduct one-half the menstrual interval; while those who consider that conception can only take place at a menstrual period, date either from the last catamenia, or from that which should have happened, but for conception. This estimate being compared with the period of quickening, a result is obtained sufficiently

accurate for ordinary practical purposes, but not precise enough for legal evidence. Other indications have, therefore, been sought for. Peculiar sensations are experienced by some women at the time of conception; some cases of this kind, described by Dr. Montgomery, would tend to fix the duration of pregnancy at 280 days. In other cases it has been ascertained by the date of a solitary intercourse, which, of course, fixes the date of conception; the same period of 280 days is, from such cases, given by Sir C. Clarke and others, and from these facts many are inclined to regard that period as the correct duration of pregnancy. To this opinion, however, Dr. Murphy does not subscribe, as the cases are comparatively few in number, and, if the rule were different, might easily form an exception to it without invalidating it. He would, therefore, call in the aid of statistics for the solution of the problem; this he commenced some years since, at the University College Hospital, when forming a register of obstetric cases. The following method was adopted:—When a letter for attendance was applied for, an inquiry was made as to the catamenia, the age of the applicant at its commencement, its period, and its last appearance. With regard to the last question, some could only give the month, others were precise as to the date, and some were too irregular to date from. The last were excluded from the inquiry; as, for instance, some who were nursing either had no change, or a very irregular one; others had been always irregular before pregnancy, and therefore could not be depended on; and again, with others, the catamenia had evidently continued after conception. All these were excluded as the others were noted, and when delivery occurred, that also was noted, the interval between the two giving the gross duration of pregnancy, which was afterwards corrected, so as to make as near an approach to accuracy as possible. Of these cases, some time back, a table of 186 was formed. The corrections were made as follows:—If the period exceeded 280 days, and the woman had given the exact date when she was last unwell, the whole menstrual interval was deducted; so, if the whole period were 328 days, and twenty-eight days were the menstrual interval, 300 days would be regarded as the true duration. It was considered that the woman might be in error, and it was thought safer to suppose that conception occurred just before the catamenia which had been arrested. Subsequently 280 days were regarded as the true period, and in any cases that exceed, the menstrual period is deducted, the result being presumed to be accurate. From his records of 965 cases, Dr. Murphy has formed four tables:—1st, those in which the duration of pregnancy exceeded 280 days, including 303 cases; 2nd, those that are exactly that period, included 378 cases; 3rd, those between 260 and 280 days, including 201 cases; and 4th, those below 260, including 83 cases. The 4th, or last table, he (Dr. Murphy) looks upon as instances of premature labour. From these tables he gathers that the duration of pregnancy is not a fixed but a variable period, as in the lower animals, varying, however, only within certain limits. Those limits are not yet ascertained. He regards 260 days, or 37 weeks, as the shortest period; he has attended mature infants born at that date. The longest period is yet *sub judice*, the cases in the first table being yet under examination, and requiring correction.—Reported in *Lancet, Medical Times*, &c., October 18th.

On Infantile Coma.—By Herbert Barker, M.D.

Dr. Barker describes a form of coma in children, which he thinks has not been previously noticed. All his cases, five in number, were dry nursed. The drowsiness comes on a few days after birth, and gradually depens into coma. At first the child can be roused to take food, but eventually it appears to be in a constant sleep. The evacuations were not the same in all the cases, and there was no constancy in the appearance of the urine. The surface becomes cool and the action of the heart feeble, and the respiration at the same time becoming slower, the surface of the body and the conjunctiva becomes deeply tinged yellow.

In inquiring into the cause of the symptoms the author attaches due importance to the biliary derangement, and attributes the coma to the circulation of bile through the brain. In his treatment of the three first cases, which was directed towards inducing a proper elimination of bile, he was unsuccessful. He was therefore induced in the next to try a wet nurse, although from the deep sleep the child was in, it was almost impossible to get it to suck. At length it was able to do so, soon after which the yellow colour began to fade, and at the same time the coma diminished. The same rapid amendment, by the same measures, occurred in another instance.—*Medical Times*, October 11, 1851.

Correspondence.

THE NEW SUPERINTENDENT OF THE ARMY MEDICAL DEPARTMENT, (DR. ANDREW SMITH,) AND HIS ARRANGEMENTS FOR THE MEDICAL SERVICE OF THE MILITARY LUNATIC ASYLUM AT YARMOUTH.

Gonville and Caius College, Cambridge,
October 25, 1851.

Dr. Lockhart Robertson, lately Assistant-Physician to the Military Lunatic Asylum at Yarmouth, requests the Editor of the *Provincial Medical and Surgical Journal* would do him the favour of inserting in that journal the two enclosed letters, which relate the cause of Dr. Robertson's retirement from the Medical Department of the Army, and which appear to him to involve a principle sufficiently important to interest the profession generally.

In explanation of these letters, it may be here stated, that two medical officers are, by the Secretary-at-War, allowed for the service of the Military Lunatic Asylum, of the relative rank of Surgeon and Assistant-Surgeon to the Forces, the appointment of whom is vested in the Superintendent of the Medical Department. These two appointments are considered by him quite distinct, the junior officer not being, in his

opinion, entitled to succeed the senior on his retirement, contrary to the practice observed in the Medical Department of the Household Brigade, which is more immediately under the Commander-in-Chief, and less in connection with the Army Medical Board. Thus, when, in 1849, Dr. Sillery, retiring on half-pay, resigned, in consequence of his being ordered for foreign service, the charge of the Asylum over which he had for seven years so ably presided, (remodelling it entirely during that period,) Mr. Cumning, an old officer, who had served in the American war,* but who had never been within a lunatic asylum, and was quite ignorant of the subject, both theoretically and practically, was appointed in his stead, although representations of Dr. Robertson's fitness for the charge were made to Sir J. McGrigor, then head of the Medical Department, by (among others) two leading members of the Lunacy Commission.

By the enclosed letters it will farther appear, that it is not even considered by the present Superintendent of the Army Medical Department desirable that officers selected, as Dr. Robertson was, especially for the service of the Asylum, should be permitted to remain at their relative posts, but rather that the appointments at the Military Lunatic Asylum should follow the ordinary routine of military rotation, and be periodically changed and filled by regimental officers necessarily unconversant with the treatment of mental disease—a practice contrary to that observed at the Naval Lunatic Asylum at Haslar, or indeed at the other military establishments under the Secretary-at-War, as Chelsea Hospital, the military prisons, &c., &c. It was to oppose so mischievous a practice—alike unfair to himself, and injurious to the interests of the patients and to the scientific *status* of the Asylum, that Dr. Robertson felt himself bound, when thus ordered for regimental duty, to tender his resignation, appealing at the same time to the Secretary-at-War, from whom a few months before he had received an assurance that in the arrangements of the medical service of the Military Lunatic Asylum, under the new Superintendent, "it would be the desire of every Secretary-at-War to see the establishment at Yarmouth placed on the best possible footing, and that nothing would be done which would in any way injure the interests of that Institution, or of the persons connected with it." The issue of this appeal will be best related by the enclosed letters :—

(Letter 1.)

War Office, 26 September, 1851.

Sir,—I am directed to acknowledge the receipt of your letter of the 25th August last, reporting that upon your having been required to prepare for your removal from Yarmouth to be employed in the general service of the Army, you had resigned your commission, and to acquaint you that the Secretary-at-War considers that the Superintendent of the Army Medical Department has been guided by a due regard to the public service in all that has occurred; the acceptance of a commission rendering every officer liable to the varied home and foreign service of the Army. The certificate* enclosed in your letter is herewith returned.

I am, Sir, your obedient Servant,

(Signed) L. Sulivan,

Deputy Secretary-at-War.

Dr. C. L. Robertson, &c., &c., &c.

(Letter 2.)

Military Lunatic Asylum,

Gt. Yarmouth, September 29, 1851.

Sir,—I have the honour to acknowledge the receipt of your letter of the 26th inst., acquainting me that the Secretary-at-War approves of the recent arrangements of Dr. Smith, which have forced me to tender the resignation of my commission.

In reply thereto I would desire respectfully to observe—

1. That, while I in no way presume to question the judgment of the Secretary-at-War as to how the arrangements in question may affect the interests of the service generally, it cannot, on the other hand, I think, be questioned by any competent member of the medical profession, that the practice of frequently handing over the insane patients of the Army to the care of officers quite unconversant with the practice of this special department of medicine, is alike injurious to their interests, and to the scientific *status* of the Military Lunatic Asylum. So uniform is the opinion and practice of the medical profession in this regard, that I deem it quite superfluous to enlarge on it. I would merely add, that any reference to H. M. Commissioners must necessarily support this view.

2. That, referring to my memorial to the Secretary-at-War of the 3rd of February, 1851, and to his assurance in reply that nothing would be done (in the arrangements of the medical service of this Establishment) which would in any way injure the interests of the institution or of the persons connected with it,† I must humbly submit that Dr. Smith's intention of employing me on the general service of the army, if not injurious to the interests of this establishment, is most certainly so to mine.

3. That, while admitting the general principle involved in your statement, that the acceptance of a commission renders every officer liable to the varied home and foreign service of the Army, I feel it due to the position I have taken to state, that so far from having accepted my commission with this implied condition, I, in the

* Consequently, he ought long ago to have retired, medical knowledge unlike Madeira wine, not improving simply by age and several voyages to the West Indies.

* A certificate, recommending Dr. Robertson, in a most flattering manner, to the notice of the Secretary-at-War, as a fit person to be entrusted with the medical charge of the Military Lunatic Asylum, and signed by Dr. Skae, Dr. Browne, Sir Alexander Morison, M.D., Dr. Sutherland, Dr. Winslow, Dr. Kirkman, Dr. Mackintosh, Dr. Wingett.

† Copy of the Secretary-at-War's letter thus above referred to.

"War Office, February 8, 1851.

"Sir,—I have submitted to Mr. Maule your memorial of the 3rd inst., soliciting that the medical officers of the Asylum at Yarmouth may enjoy the same permanence in their offices as the medical officers of the military establishments under the Secretary-at-War.

"Mr. Maule desires me to inform you that he feels assured it will be the wish of every Secretary-at-War to see the establishment at Yarmouth placed on the best possible footing, and that nothing will be done which will in any way injure the interests of that institution or the persons connected with it.

"I am, Sir, your most obedient servant,

"(Signed) "George D. Ramsay.

"Dr. Robertson, &c., &c., &c."

first instance, in July, 1846, declined (when offered it) the usual appointment in the medical department of the Army, and only afterwards accepted of my commission on receiving from Sir James McGrigor the unsolicited offer of the appointmeut which I have for nearly five years held at this Asylum. In order to this I resigned a permanent appointment at the Cumberland Asylum, the duties of which were agreeable to my own feelings, and in furtherance of my resolution to devote myself to the improvement of the science of psychological medicine.

Having thus been specially brought into the service for the duty of the Military Lunatic Hospital, I feel that I have been most hardly dealt with by the recent decision of the Superintendent to remove me from the same, and I cannot—much, as for many reasons I shall, regret leaving Her Majesty's service—so long as Mr. Maule expresses his approval of this step, in any way recede from the position I have taken. I feel it to be a duty I owe, alike to the profession and to myself, at no cost to compromise the principle which I hold to be violated by my removal from the Asylum, viz., *the recognition of special professional fitness in the distribution of the patronage of the Medical Department of the Army in place of that of mere military routine.*

I have the honour to be, Sir
Your most obedient servant,
(Signed) C. Lockhart Robertson,
Fellow of the Royal College of Physicians, Edin.
The Deputy Secretary-at-War.

ON MENTAL ALIENATION.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—An important consideration now occurs, viz.,—Whether the present general state of insanity does not offer a different form of symptoms from that of former years?—in other words, whether an alteration has not been induced, whether its active form is not now less frequent, and an asthenic and chronic state the more dominant character?

At the last meeting of our Association, at Brighton, Mr. Williams read an excellent paper upon the change which for some years back has been observable in the type of disease, particularly of the inflammatory kind. In that paper I think no allusion was made to mania, but if his argument be correct, that disease must also enter into its category. I believe the statement to be true, and that we may run through the nosology, and find the order phlegmasiæ, with Cullen's definition, not bearing so greatly upon the general character of disease as older writers have detailed. I am certain the statistics of insanity, as far as I have been enabled to search them, bear me out in this remark; and that it is not because I have more experience, and my practice perhaps more regulated, that I make any surmise upon this point. Such alteration must lead to practical inferences as to the modification of treatment; and although many may have congratulated themselves upon proposed or supposed melioration, yet the fact may be assumed that the severer restraint of earlier days has not been wanted in our later ones. Some enthusiastic minds have been led to carry this too far, as is the fate of all reforms; but to a well-judged observance of the propriety of relaxation of restraint, I believe the merit must be accorded to the management of the Quaker's Asylum (The Retreat) in the first place, and all improvements proceeding thence, with quiet vigilance, and without any attempt to extort public approbation. This plan was early adopted by my revered relative in his establishment of a private asylum, and I hesitate not to say has been cautiously maintained up to this day. Again, experience now informs us that the cases of long protracted insanity are more easily managed than the early ones, and that in many instances of periodic paroxysms the state and duration become pretty well known, and that whatever means of restraint are necessary, are made commensurate with that knowledge. The fashion of the day, however, is to run into extremes, to allow more liberty than is consistent with proper management, without attending to the due regulation of the patient's mind.

Calmness, quietude, patience, *attention* to the bodily health, *attention* to delusive feelings and actions, these are the essential modes of good government, which include the endeavour to cure; but to submit to every freak, to reason with unreason, to allow passion its full extent of violence, is a doctrine that seems ready to be taught, and may be agreeable enough to those who give advice in the plenitude of their ignorance.

Much has been said and written about employment, but no very well reasoned facts have been brought to bear upon the subject. The writers appear to me to have arrived at hasty conclusions from the condition and circumstances under which they have been placed. "Non omnia possumus omnes." The statistics of pauper asylums produce an account of patients employed, work done, the manual labour of the male, the domestic habits of the female, for the most part usefully employed; and it is said that some pauper asylums have been enabled to pay a great part of the expenses. Be it so; there can be no doubt that employment must generally be useful. Who can deny that it affords health to the body, and invigoration to the mind; but let it be asked who are the subjects submitted to this rule? Those who from early life have been submitted to it, who are subordinate, and with no great difficulty induced to employ themselves in their former vocation—here imitation will do much, obligation much more. In a private establishment you cannot force *him* to work who has never known it—who has not been accustomed to subordination, but rather to command others. Nor am I certain it is a good plan of endeavouring to restore any one to their senses by making them feel themselves inferior, perhaps degraded beings; nor can it be enforced as it may be elsewhere. With females there is much less difficulty; their education has taught them the use of their fingers in various modes of industrial and amusing employment, which is readily engaged in by many. I have not, however, observed that the cures in one class are greater than those in another; nor in the working asylums than in the non-working, (so called for the sake of distinction); and one observation I have particularly made, and ever been

attentive to it,—how short are the hours, how fleeting. to the unsteadied mind.

The care of insanity does not depend upon the "dance, the spade, or the tambour."

Dr. Gregory has advanced, in his "Letters to a Candid Inquirer," certain opinions concerning the theory of insanity, which I shall not now discuss. An experience of thirty years teaches me it would he beating the air: but when his "odyle" can be obtained—when his imaginative conjectures can be condensed into solidism, then will be the time to gaze, to pass, dispass, to administer globules of the "insane root," which, according to the doctrine of *the then day*, must inevitably cure the disease.

In this interval we may be allowed to reason upon facts, instead of losing ourselves in the "clouds of science."

> ——— The human mind may strain,
> And in its labours will most likely gain
> The granted knowledge of the laws of life,—
> Their mutual action, their continued strife.
>
> Yet, all in order. Those will be content
> Who widely reason, judge of what is meant,
> Believing truly that Almighty Power
> Has given to man his day, his strength, unto his hour.

At present I cannot class among the well-judging reasoners upon this disease, extraordinary as it is, those who seek for its emanations beyond the credible influence we are yet permitted to perceive of the union and action of the material body with and upon the immaterial spirit.

Yours obediently,

E. B.

Medical Intelligence.

MEDICAL BENEVOLENT COLLEGE.

At a meeting of the medical practitioners of Leamington and Warwick, held at Leamington, October 9th, 1851, Dr. Jeaffreson in the chair, the following resolutions were passed:—

First. Proposed by Mr. Prichard, and seconded by Mr. Boulton, "That the Establishment of an Asylum for Distressed Medical Men or their Widows, and a School for the Education of their Sons, is an object worthy of the cordial co-operation of the profession, and has strong claims on the sympathy of the public."

Second. Proposed by Dr. Homer, and seconded by Mr. Hiron, "That the members of the medical profession in Leamington and Warwick, forming this meeting, pledge themselves by all available means to assist the accomplishment of so desirable an object, and earnestly exhort their professional brethren and their friends throughout the country to aid them in carrying it out."

Third. Proposed by Dr. Franklin, and seconded by Mr. Blenkinsop, "That a local committee be formed, consisting of the following gentlemen, for the purpose of co-operating with the central committee in London, and on receiving subscriptions and donations from the profession:—Dr. Jeaffreson, Mr. Middleton, Mr. Boulton, Dr. Homer, Dr. Franklin, Mr. Jones, Mr. Blenkinsop, Mr. Babington, Mr. Hiron, Mr. Watson, and Mr. Prichard."

Fourth. Proposed by Mr. Blenkinsop, and seconded by Mr. Busby, "That Dr. Jeaffreson be requested to accept the office of Chairman, and Mr. Prichard that of Honorary Secretary and Treasurer to the local committee."

Subscriptions and donations will be thankfully received by the Local Treasurer, or by any member of the committee.

MESSRS. HIGHLEY AND SON, *v.* QUACK PUBLICATIONS.

The profession will be much gratified on being made acquainted with the important fact that Messrs. Highley and Son, the eminent medical publishers of Fleet Street, and booksellers to the Royal College of Surgeons of England, have declined the further publication of all homœopathic, hydropathic, and other works devoted to the advancement of quackery.

CENTRAL CRIMINAL LUNATIC ASYLUM.

The visitors of the County Lunatic Asylum, Gloucester, have forwarded a memorial to the Secretary of State for the Home Department, for the establishment of a Central Criminal Lunatic Asylum.

EPIDEMIOLOGICAL SOCIETY.

The first ordinary meeting of the present session was held at the house of the Royal Medical and Chirurgical Society, 53, Berners Street, on Monday, the 3rd of November, Dr. Babington in the chair. An address was read by the President, in which he stated the progress of the Society since first he had the honour of addressing the members beneath the same roof in December last, and the nature and operations of the various committees formed since that period. A paper was read by the Honorary Secretary, written by Mr. Gardner, of Notting Hill, "On Small-pox and Vaccination," which elicited much applause. Mr. Grainger spoke at some length. Dr. Babington and Dr. Hare also took part in the discussion. Several new members and corresponding members were proposed. The meeting was well attended.

UNIVERSITY OF CAMBRIDGE.

LECTURES ON SUBJECTS CONNECTED WITH THE STUDY OF MEDICINE FOR THE ENSUING YEAR.

Michaelmas Term.—Comparative Anatomy and Physiology, by the Professor of Anatomy—Human Anatomy and Physiology, by the Professor of Anatomy—Institutes of Medicine and Preservation of Health, by the Downing Professor of Medicine—Medical Clinical Lectures by the Regius Professor of Physic, at the Hospital.

Lent Term.—General Pathology, by the Regius Professor of Physic—Human Anatomy and Physiology. (Course continued.)—Chemisty, by the Professor of Chemistry—Medical Clinical Lectures, by the Linacre

Lecturer at the Hospital—Materia Medica and Pharmacy, by the Downing Professor of Medicine.

Easter Term.—Special Pathology, by the Regius Professor of Physic—Botany, by the Professor of Botany—General Therapeutics and Clinical Medicine, by the Downing Professor of Medicine.

A course of Lectures on Surgery by Mr. Humphry.

Attendance on Medical and Surgical Practice at the Hospital, daily, at 11 A.M., recognised by the Royal Colleges of Physicians and Surgeons.

Attendance on the Lectures on Human Anatomy and Physiology, and on General Pathology and Dissections, are recognised by the Royal College of Surgeons, London, as one of the Sessional Courses required by the Regulations of the Council of that College.

Students entered to the Practice of the Hospital are admitted to the Clinical Lectures and the Lectures on Surgery without additional fee.

Cambridge, October, 1851.

HARVEIAN SOCIETY.

Office Bearers for the Session 1851-52.—*Presidents:* Dr. J. Bird and Mr. H. Obré.—*Treasurer:* Dr. J. Ridge.—*Honorary Secretary:* Dr. R. H. Powell.—*Members of Council:* Dr. Chowne, Dr. R. Quain, and Mr. H. B. Norman; *ex-officio* members inclusive.

ROYAL COLLEGE OF SURGEONS.

The Classical and Mathematical Examinations for the Fellowship commenced on Tuesday last. The Professional Examinations will take place in the first week of the ensuing month.

The following gentlemen were admitted members on the 24th inst:—Robert William Ellis, Bristol; John Tom Gabriel, Devonport; Thomas John Hughes, Lampeter, Cardiganshire; John Kearns, Kilkenny; John M. Kidd, Edinburgh; George William Paynter, Australia; William Barnes Rainey, Spilsby, Lincolnshire; George Money Swinhoe, Calcutta.

SOCIETY OF APOTHECARIES

Gentlemen admitted on Thursday, October 23:—George Atkin, Sheffield; William Davey Haye, Callington, Cornwall; Thomas Nash, Liverpool; Thomas Odell, Newport Pagnell; Edward Horatio Swete, Sheffield.

Gentlemen admitted on Thursday, October 30:—William Boyle Chavasse, Birmingham; Charles Edward Bowman Danson, Pocklington, York; Edwin Josiah Miles, Gillingham, Dorset; Richard Nugent, Antigua; William Owen, Llanfair, Montgomery.

BOOKS RECEIVED FOR REVIEW.

Lectures on the Principles and Practice of Surgery. By Bransby B. Cooper, F.R.S., &c. London: J. Churchill, 1851. pp. 964.

On the Transmission from Parent to Offspring of Some Forms of Disease. By James Whitehead, M.D., F.R.C.S., &c. London: J. Churchill. 1851. pp. 351.

A History of Epidemic Pestilences, from the Earliest Ages. By Edward Bascombe, M.D. London: J. Churchill. 1851. pp. 250.

The Prevention and Cure of Diseases by Movements. By M. Roth, M.D. London: J. Churchill. 1851. pp. 302.

A Manual of Physiology. By W. B. Carpenter, M.D., F.R.S., F.G.S., Second Edition. London: J. Churchill. 1851. pp. 616.

Bradshaw's Companion to the Continent. By Edwin Lee, Esq. London: W. J. Adams. 1851. pp. 408.

Report of the Proceedings of the Pathological Society of London. London: Bentley and Co. 1850-1. pp. 196.

Report of the Alleged Lunatics' Friend Society. 1851. Pamphlet. pp. 39.

Summary of Suggestions for Additions to the Law of Lunacy. Pamphlet. pp. 11.

A Letter to the Right Hon. the Committee of the House of Lords, sitting on the Masters' Jurisdiction. Bath. 1851.

The Medical Examiner—August, 1850. Philadelphia.

The American Journal of Dental Science. Philadelphia. 1851.—April and July.

The Dublin Quarterly Journal.

The Charleston Medical Journal—September. 1851.

The London Journal of Medicine—November, 1851.

The Medical Examiner—September and October, 1851.

The American Journal of Dental Science—October, 1851.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen will observe that the Annual Subscriptions become due on the First of Junuary, those who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association, Worcester.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, September, 1851.

ERRATUM.—In the letter "On Mr. Owen's Case of Spontaneous Amputation of the Limbs of the Fœtus in Utero," page 613, col. 1, line 30, from the bottom, for "in the *limb* itself," read "in the *funis* itself."

TO CORRESPONDENTS.

Communications have been received from Mr. Mallett, Dr. Nelson (twice), Mr. West, Dr. R. Hall, Mr. Lingen, Mr. Le Gay Brewston, Birmingham Pathological Society, and Mr. E. Bishop.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

CLINICAL LECTURES

ON THE

PRACTICE OF PHYSIC,

DELIVERED IN THE

THEATRE OF QUEEN'S COLLEGE, BIRMINGHAM.

By DAVID NELSON, M.D., Edin.,

Physician to the Queen's Hospital, and Professor of Clinical Medicine, &c.

LECTURE IX.

On the Morbid Condition of the Lungs and Respiratory Tubes.

Gentlemen,—These affections, like those of the other tissues or organs, may be synthetically reduced, according to the rules of simplification already propounded, to three orders, viz.,—those of a purely functional or nervous kind in the first place; secondly, those involving anæmia or hyperæmia; and thirdly, degenerations.

Before entering, however, into the consideration of these specific maladies, I shall take a very general review of the essential structure of the lungs, and the principal features to be observed with regard to their capacity, and the different motions, sounds, and discharges, which may characterize them in the various phases of health and disease.

In the human body, then, the atmospheric air is admitted into the system by first passing through the mouth or nostrils to the larynx, thence down the trachea, and next through the bronchi and their ramifications, into the ultimate cellules of the pulmonary tissues. The whole of this extensive track, so extensive as to be about ten times more than the superficial measurement of the body, is lined by a mucous membrane, with areolar and muscular tissue underneath. The mucous membrane of the mouth is covered with tesselated epithelium, but that of the air passages, more strictly speaking, is clothed with a cylindrical ciliated epithelium, whose infinitely delicate ciliæ wave to and fro at every inspiration with a perpetual stroking motion. In the event of any obstruction, either in the mouth or nostrils, these organs may readily supply the offices of one another, and, generally speaking, the first point of importance and danger, as regards respiratory affections, occurs in the larynx; an organ so complicate, delicate, and sensitive, that it is frequently liable to irritation and all its consequences, so that a patient may die of suffocation from the closure of this principal passage alone, while the general body of the lungs is in a perfectly healthy state. The same observation, in a minor degree, may be applied to the trachea, as in croup; though the structure of that passage is comparatively simple, being a series of imperfect cartilaginous rings controlled by muscular fibres, and covered by the usual membranes. The bronchi and bronchilli are similar in their structure to the trachea, but upon a diminished scale. What these want, however, in individual size, is made up by their number and greater extension of surface; so that, while obstructions in the trachea owe their danger to the fact of its being the one first passage; those in the bronchi and bronchilli are rather serious on account of the extent of surface involved. This latter observation applies with infinitely greater force to the ultimate cellules, as illustrated in pneumonia, &c., on the condition of which the vital capacity for air altogether depends. As all of you are aware, there are three lobes of lung on the right side of the chest, and two lobes on the left, the room of the third being here occupied by the heart, whose situation has already been described. While the inward lining of the lungs is a mucous membrane, that which lines their exterior is of a serous character, and being reflected back upon the walls of the chest, and upper surface of the diaphragm, &c. &c., is well known as the pleura, the smooth and moist faces of which admit of a free and easy gliding upon each other during the acts necessary to respiration. The lungs, then, occupy a space within the chest, corresponding pretty nearly with slanting lines drawn from the xyphoid cartilage along the last true and all the false costal cartilages to the last dorsal and first lumbar vertebræ upwards, to the supra clavicular spaces. Their capacity for air has been determined by Dr. Hutchinson to depend on the height of the individual, and not on his bulk; and you will find, on referring to his essays on that subject, what he gives as the natural cubic measurement of their contents, according to the rise or fall of altitude. Thus, the capacity of a medium man of 5ft. 8in. is laid down at about 240 cubic inches, while that of one of 6ft. is about 270; no matter what the relative bulk or weight may be. As you will better understand, however, in ounces than in cubic inches, what the amount of air is, I have had my hospital spirometer graduated accordingly, and we find that a moderate sized man of 5ft. 8in., and with sound lungs, will fill the glass at his full expiration to the extent of 128 ounces, while a tall subject of 6ft. will bring down the column of air so as to represent 152 ounces. Several of our consumptive patients, on the other hand, of 5ft. 8in. and upwards, have not been able to expire more than 32 ounces. These comparisons are of the very highest importance; and not less so are those which relate to the bulging of the intercostal spaces under accumulation of fluid, and the sinking of the clavicle, &c., under solidification or destruction of the lung. The motions by which the respiratory acts are naturally effected are, the alternate contraction and relaxation of the diaphragm and muscles of the thorax, &c., so gently exerted as to excite no sense of effort. These acts are partly under the voluntary, but mostly under the government of the involuntary nerves; and, during the period of rest, or after breakfast in the morning, the respirations, in a perfectly healthy and well-formed adult male, will amount to little more than ten in the minute. Under exercise, even in the healthiest person, they may be considerably augmented; and then the muscular motions will also be much altered, inasmuch as additional muscles will be called into play, but more especially those of the neck. In disease there are numerous modifications of such motions, both as to

character and frequency. Thus we may have dilatation of the nostrils, as in heart disease; or violent efforts of the muscles of the neck or abdomen, under different affections of the bowels or chest, or air passages, as constantly illustrated in the house. The respirations may also naturally diminish under affections of the brain, or other portions of the nervous system, from a diminished excito-motive sensibility. Or they may, on the other hand, be greatly increased, even to 60 in the minute, (as in the little girl, Bates, with pneumonia, in Heath, with phthisis, and in the old man, Malabone, with asthma); either from diminished capacity of the lungs, or obstructed passages, or from such inflammatory or nervous pain of the pleura, &c., as shall deter the sufferer from making other than a very slight inspiration at a time. Thus the number of the respirations becomes a matter of much consequence in forming a diagnosis; yet not without comparing it, at the same time, with the further evidences afforded by auscultation and percussion.

As to the former kind of evidence, it will be obvious to you, on considering the anatomical structure of the organ, that different sounds will be produced by the air while passing through the different parts of which the lung is composed. Thus, the sounds heard through the stethoscope have been named according to the natural situations in which they should be found. A loud and tubal blowing sound will be heard over the trachea, which is therefore called tracheal respiration. The same sound, considerably diminished, is likewise recognised over the larger bronchi, at each side of the upper part of the sternum, and is called bronchial respiration. As these subdivide and enter as bronchilli into the ultimate cellules of the general tissue, the character of the sound is greatly altered, and you have only that gently breathing whiff, or, in young subjects, that soft continuous buzz, which is known as vesicular respiration. To discriminate rapidly and skillfully between these different sounds requires a nice ear; but you have only one course to pursue, and that is, perpetual practice with the cylinder. Under disease these natural sounds may become altered, or displaced, or obliterated. The tracheal respiration may become hissing, rough, or stridulous, from sundry alterations of structure, as in Dremer, with laryngeal degeneration, and the girl Perkins, with laryngitis; or the bronchial may become, from similar causes, hissing, harsh, cooing, or chirping; or the vesicular may assume a crepitant character, or be completely absent. Thus, in those patients who have bronchitis or incipient phthisis the sounds will be gently rough; where there is a dry cavern the hissing will be heard; and the cooing, chirping, and snoring sounds will accompany a narrowing of the tubes, whether it be simply asthmatic or inflammatory. Likewise, from dilatation of the bronchi, these may emit sounds as loud and harsh as the trachea, while the bronchilli, under solidification of the surrounding vesicular structure, may, in like manner, give forth a bronchial blowing, in portions of the lung where nothing but the vesicular murmur ought to be heard. Under the existence of caverns, what is called cavernous respirations, of a very hollow character, will be perceived, while the rest of the structure may be so solidified that no sound is heard whatever. It is also to be understood that these must be altered under the presence of fluids. In the vesicular structure such fluids will produce what is called crepitation, or the small crackling murmur similar to that emitted by common salt over coals, or from the handling of hair, or from the breaking of small bubbles in a phial. In the smaller bronchi they will produce what is called the larger crepitation; and in the larger bronchi, windpipe, or accidental caverns, they will give the marked loud sound called gurgling. Besides the cavernous or hissing respiration heard in a dry cavern, and the gurgling in a moist one, two other sounds are elicited from a hollow of this kind; one under percussion of the hammer, viz.,—sharp reverberation, and the other, passing through the cylinder, as recognised under the term *pectoriloquy*. Œgophony, as you are aware, is that tremulous goat-like sound produced by the undulation of water under the force of the voice.

From percussion we derive many important points of evidence. In the healthy condition there will be a clear resonance from every part of the chest, except where very thick muscles intervene, or over the region of the liver or heart; and the evidences of disease, in so far as the partial or total obliteration of the pulmonary tissue is concerned, whether proceeding from solidification or deposits of fluid, or of tumours, will be in proportion to the partial or total obscuration of the resonant sound under percussion. On the contrary, it may be greatly increased under the condition of emphysema. All this is, in most cases, a question of degree, the nice perception of which is only to be attained by long and continued practice. For one instance of extreme amphoric resonance, or clay-like dulness, you will find twenty instances of graduated diminution or increase of pectoral sound. As a means of discriminating such nice differences you will find in the pleximeter and hammer a very great assistance. They have many advantages over the naked hands, among which I shall only enumerate the facts that they elicit clearer sounds from the depths of the chest than the hands are able to do; that there is greater delicacy in their application; that they are less painful, both to the patient and practitioner; and that by their means we can mark out the line of demarcation between healthy and unhealthy parts with much greater precision. In an extensive practice the fingers of the physician will often become painful, and even affected with periostitis by frequent manual percussion. The slightest tenderness, either on his own part or on the part of the patient, will thus induce him to vary the force of his stroke; whereas neither of these impediments are apt to beset the pleximeter, which, under the equal and gentle stroke of the hammer, will seldom ever give pain, unless disease be present; and even then the pain will be very moderate. There is also another evidence of excavation which has been found of great value to us in the hospital, and which, indeed, has been the invariable, and sometimes the only proof, during

life, of what has been found after death. This is that peculiar reverberation under the stroke of the hammer to which I have so repeatedly drawn attention, as indicative of the presence of a cavern, and which can only be fully elicited by the use of the pleximeter and hammer, though a practised person may readily produce it with his fingers.

As to the nature of the pulmonary discharges, there ought to be, in a state of health, almost nothing whatever, beyond the natural halitus of carbonic acid and water, &c. As the air, however, will generally be found to contain a certain amount of impurity, such impurities will always excite a certain slight irritation in the first passages, and protective exudations of thickened mucus will then be thrown out in the form of those matters which commonly proceed from the nostrils, or are hawked up from the fauces &c., even of the most healthy individuals. These healthy individuals, however, will certainly never have any actual discharge from the body of the lungs, beyond the halitus already mentioned; nor will they ever cough or expectorate, except from some cause suddenly applied from without. The slightest induction of cough, therefore, or the slightest approach to expectoration, is, so far, evidence of disease; and the amount and kind of cough and expectoration will afford a measurement of the extent and nature of such disease. Thus, there is the short, dry, uneasy cough of incipient inflammation or degeneration, and the moist and comparatively easy cough of the more advanced stages of exudation or softening. The discharges, in like manner, will vary with the varying nature of the ailment. In the first stage of hyperæmic action there will be a diminution of the secretions; while afterwards they will be more or less augmented, and more or less altered in character. Thus, we may have the frothy or thickened mucus of a common bronchitis, which may, further, be mingled with lymph, which shall rapidly change into pus, streaked, perhaps, with blood; or, if the inflammation extend to the vascular structure, where the vessels are infinitely multiplied, we may then have the whole sputum tinged red with blood. You may also have the same sort of sputum from simple relaxation of the vessels, as in the interesting case of Steel, who, at the age of 40 had hooping cough, after which rusty expectoration continued for a considerable time, without any evidence of inflammation. In phthisis the discharges vary very much, and we may either have a simple frothy mucus or a greenish fluid full of globules of muco-purulent matter, or tough thread-like balls, commonly called flocculi, also pure pus, or pus or mucus infiltrated with blood. We may likewise have the melanotic expectoration of black disorganised lungs, or the offensive emanations from gangrene or malignant disease. Besides the proper pulmonary expectoration, we should also attend to what is hawked up from the region of the fauces and larynx, as diseases of a very formidable character are apt to attack those parts, the onset of which is generally preceded by the secretion of a thick and tenacious or bloody mucus, which is not hawked up without producing an inclination to vomit, especially in the morning, and which is followed by a degenerate thickening of the parts and loss of voice; in short, by laryngeal phthisis, of which we have had several cases, and all, with one exception fatal, inasmuch as they are almost always a mere conclusion to universal destruction of the lungs. Not that I would assert that such degeneration may not sometimes commence at the larynx, but only that, in all bodies dissected here it has invariably been associated with the above universal destruction of the lungs.

All affections of these respiratory organs, according to the synthetical plan here adopted, are reducible to three orders, viz., the functional, the hyperæmic, and the degenerative. Those of a functional kind are altogether due to irregularities of the nervous action, and may either arise from affections of the nervous centres or chords themselves, or be due to a reflected excitement, the source of which may be an irritant at their peripheral expansions. Thus the sighings, the coughings, the wheezings, &c., &c., which occur in hysteria, nervous asthma, and other similar disorders, are of the former kind; while the same symptoms, being traceable to the presence of irritating gases, or morbid deposits, belong to the latter order.

The purely functional disturbances, however, are not now admitted to be so numerous as they were wont to be, because it has been found that apparently functional disturbances in one organ, are mere reflections of organic excitation in another. Thus, it is a familiar fact that chronic inflammation or other affections of the uterus, will excite pain under the left breast, and an habitual vomiting which ordinary stomachic discipline shall not subdue; that disease of the liver will give rise to pains in the shoulder; and that a worm in the intestines will produce sneezings, itchings at the nose and anus, grindings of the teeth, and an incessant cough, or even epilepsy or chorea. Even simple sensations being impressed upon one sense, will sometimes be propagated to the source of another, and be so reflected upon its expansite nerves as to excite a seemingly functional disturbance. Thus, Dr. Allen Thomson, of Glasgow, is wont to relate a peculiarity of this sort in his own constitution, and states that he no sooner crosses to the sunny side of the street, than the sudden change effected upon the retina is swept backwards, and returns along the nasal nerves, so as to excite a fit of sneezing. Even in those convulsive actions of the motor nerves, which are not traceable either to irritation of their own coadjutor sensifics, or any other peripheral source, but only to a morbid condition of the motor centres or nerves themselves, the mere presence of excess of blood, or of vitiated blood, &c., within these centres, is to be accepted as a physical cause, quite sufficient to exclude such convulsions or spasms, from the category of mere *functional* lesions. Such lesions, indeed, are only to be admitted, when no physical causes can be discovered, and a wide enough field is offered to our observation, even within this strict limitation of the term functional. The chief source of such kind of disturbance appears to be emotion, the exaltation of which, therefore, may induce a simulation of numerous organic diseases. The

instances of sighing, weeping, screaming, vomiting, purging, passing urine, and aborting, under no other assignable cause than a sudden powerful emotion, are common and tangible proofs of that perturbing influence from within, which is so mysterious in its rise, and so eccentric in its proceedings, that it has always proved the principal obstacle to any positive and invariable certainty in medical reasonings. It may be, as it has been, questioned, whether such tangible results could accrue from simple emotion alone unless there existed some simultaneous derangement of bodily health; by which reasoning, the whole theory of nervous disorders would be expunged from our nosological tables. But, having already granted that such nervous theory should be strictly limited, I must as positively hold, that there is no improbability whatever, under the facts above instanced, that the emotional centres should so propagate their primary perturbation to the sources of voluntary and involuntary motion, and so stimulate them that the controlling power should be overcome, and various peripheral manifestations be exhibited without any physical defect being discoverable within the frame, except only a delicate and sensitive organization, as inferable from the results.

Whether, however, the exciting causes be physical or functional, there can be little doubt of the effects being of a spasmodic or convulsive nature, as indicated by the sudden rapidity of their onset and departure, and their subduction by those remedies which are known to influence nervous actions. Under this head we have to place all affections of that nature which attack the nose, the larynx, the trachea, or lungs. In the nose the chief manifestation consists in sneezing, or in certain subjective perceptions irrespective of any external cause. Sneezing may arise either from an external irritant, or the presence of hyperæmia, as in the onset of more serious pulmonary complaints, or from some merely functional derangement of the nerves themselves. When similar occurrences take place in the larynx, they excite cough, and become of vital importance, on account of its being the sole passage by which air may reach the system. In this situation there may occur spasmodic constriction dependent on the circulation of poisons in the blood, or violent convulsions may interfere with the act of respiration under the intrusion of any foreign matter, whether it be solid or liquid; or there may be an hyperæmia, or such a deposit of solid, or effusion of fluid, matter, as may physically excite local convulsions. The same argument applies to the trachea, bronchi, bronchilli, and vesicles of the lungs, because they are each characterized by a nervous and muscular structure. One eminent physician, it is true, (Dr. Clutterbuck,) did object to the possibility of any spasm of the trachea, under the argument that its rings were cartilaginous, and did not admit of any constrictive action; but the anatomical fact was forgotten by him that these tracheal rings are not perfect, but only partial, and that, as the intermediate tissue is clearly muscular, spasm and convulsion may take place within it as readily as elsewhere, and therefore that laryngismus and spasmodic croup are maladies of as veritable a kind as is either spasm of the stomach or of the intestines. The distinction is a matter of very great importance in practice, as the life of the patient might be sacrificed by any want of discrimination on the part of the attendant, and that within a space of time calculated to startle any observer. But the difference between an organic and spasmodic attack is usually to be drawn from the suddenness of the latter, coupled with the slowness of the pulse and general absence of fever. Of the existence of spasmodic contraction within the finer ramifications of the intra-pulmonary muscular structure, there exists no doubt whatever, and it has universally been admitted to be the immediate cause of a fit of asthma. Analytical nosologists have divided asthma into spasmodic, organic, dry, moist, vapourous, &c., &c. All this I take to be an unnecessary complexity, for asthma is always essentially spasmodic, whatever may be the exciting cause, and we are no more entitled to puzzle the observer by mixing it up unnecessarily with other coincident conditions than we are entitled to divide and subdivide coughs and sneezings, &c., &c., until the acquisition of their mere names becomes an irksome task. All such affections attack by fits, according to the irritation of the exciting cause, or the excitability of the nervous system, and the only important distinction we have to draw is, as to whether that cause comes from within or from without, that is to say, whether it be a perturbed functional state of the nervous centres or chords themselves, or whether it arise from a foreign irritant applied to the local sensorial surface, or elsewhere, and propagated back by reflex action to the motor expansions of the same organ. Thus a cough, or a fit of coughing, is clearly a nervous act, whether it proceed from inhalation of dust, or from tubercle or pneumonia; and so asthmatic constriction is a truly nervous condition, whether it be dependent on some change in the constitution of the atmosphere, or on the presence of blood or other matters in the lungs, or on simple mental emotions. It is, in short, a morbid muscular contraction, and is never to be confounded with any permanent narrowing of the respiratory tubes by organic deposits. This may appear a self-evident proposition, but it often becomes necessary to remind people of such axioms, and bring back their excursive speculations to the simplicity of natural reasoning. It may be averred that such divisions are useful, because, if they were not ever present to the mind of the practitioner, he might be apt to apply simple antispasmodics in cases involving great engorgement of blood, or solid or fluid deposits. But I contend, that so far as spasm is concerned, it would be relieved by such agencies, even in the presence of organic causes; and certainly the physiological facts and reasonings upon which this view is based leave no ground for the assumption, that any practitioner so disciplined in his profession should be likely to expect that the physical conditions that excited the spasmodic action, could be removed by the agencies alluded to. The presence of a surgical wound, or of irritating matters within the uterus or intestines, does not pro-

hibit us from using, with good effect, sedatives and antispasmodics, when these organs are excited to painful contractions thereby. And neither do I see why a parity of reasoning should not apply to the lungs or any other part of the body, but I shall touch upon this subject again when I speak of the organic changes.

The usual symptoms of asthma are, a sense of the existing constriction, with a blueness of aspect dependent on deficient oxygenation. The patient finds his difficulty of breathing much increased on lying down, and therefore props himself up in bed when the attack is severe, or sleeps in a chair. On listening over the chest all varieties of sounds may be heard, from the sibilant chirp to the rough base note; and, if fluids are present, there may be gurgling sounds, or even the smallest crepitation, quite resembling that of pneumonia. This latter sound was very markedly heard in the chest of Peakman, whose asthma obviously depended on extensive bronchitis and œdema of the lungs, the fluid sound being, most probably, due to mucus retained within the distended vesicles. In asthma the inspiration is rather prolonged and laboured, but the expiration is much more so; and, from the fact that the retained air must have the effect of distending the vesicles, or even of making them burst into one another, a condition is produced in old asthmatic subjects called emphysema, which gives rise to that peculiarly hollow resonance under percussion which is called amphoric. But this condition, so far from affording any relief to the dyspnœa, rather increases it; for, inasmuch as the capacity for ærifiation in the blood is not dependent on the mere hollowness of the lung, but on the comparative extension of the oxygenating surface, so this breaking up of that finely-spun tissue of vessels diminishes to a considerable degree the basis of operation in the proper pulmonary function.

The proneness to asthma is commonly congenital and hereditary; but, as already observed, it may arise, like cough, from numerous external causes of irritation, and is to be treated according to the same principle as other nervous disorders. Whether there be sneezing, therefore, or common, or croupy, or hooping-cough, or asthma, they are all to be managed acccording to two rules, which are, to allay iritability, and remove, if we can, the irritating cause. The latter operation will be entered into at proper length when we come to consider the organic affections; and, for the present, I shall chiefly confine myself to the former. Pure spasm, or convulsion, is principally to be controlled by those agencies which we call sedatives, tonics, and, for paramount distinction, anti-spasmodics. All of these might act with pretty nearly the same effect, provided we had a genuine case of purely nervous action; but, inasmuch as the nervous excitation is so very often a secondary result of previous organic change, so we must be careful to appreciate all such physical causes, and refrain from the administration of such remedies as might increase them. Thus opium, arsenic, or hydrocyanic acid, might each possess equal virtue in allaying the irritability and renewing the normal powers of the nervous system; and yet opium might be highly objectionable in one case, from its tendency to produce congestion and dryness of the mucous surface; arsenic might be contraindicated in another, from the presence of acute inflammation; and hydrocyanic acid might be forbidden in a third from a consideration of the low condition of the vital powers, and a consequent tendency to faint. Thus, though in each case there is but one path to take, there are a great many paths to be avoided; and it is the nicety of perception that is here requisite which constitutes the therapeutical skill of the physician. But, while cautiously regarding the various physical changes that may have taken place, and thus avoiding the use of any medicine which may augment their intensity, there are certain pure anti-spasmodics which can seldom do harm under any circumstances, and generally effect the highest amount of benefit in almost all; such as fœtid or aromatic ammonia, or mild tobacco fumes, or castor, or sulphuric æther, or lobelia. More especially that combination of the two last medicines known as *Whitlaw's Æthereal Tincture of Lobelia*, have I found most efficacious in asthma, as illustrated by so very numerous a list of cases at our hospital; wherein the arrest of the constriction was effected, in so brief a space, that no doubt whatever could be left on any mind as to its being essentially a nervous disorder. Amongst a great many others you may recollect one lad in particular, John Taylor, aged 13, subject for eighteen months to the disease, whose respirations were so high as sixty in the minute, and whose wheezings were the loudest, roughest, sharpest, and most extensive I ever heard. With such a violent fit he entered on one day, and having taken only two doses of the tincture, he was perfectly well the next morning. I therefore draw your especial attention to this admirable compound.

I have entered thus fully into the subject, not from any shadow of doubt existing in my own mind, but because I wish to reconcile the views of the two sections of the profession called symptomatologists and morbid anatomists, and blend them into some shape of distinct pathological doctrine. Drs. Corvissart and Clutterbuck, as you may be aware, recognised the local physical causes alone in these affections, and did not admit any instance whatever of eccentric spasm or convulsions. Such assertions only illustrate the tendency of that mechanical school of philosophy which, in modern days, has darkened our horizon, and sometimes obscured the highest truths. Dr. Majendie was one of the leading apostles of it in France, and too many microscopists, chemists, and physiologists have recently been drawn down to it, to the annoyance of the observant and reflecting physician. But one glaring instance of the perversion and inconsistency of such minds is exhibited in this fact that, while they sceptically ridicule the admission of any inefficiency in immaterial, or unseen causes, they will yet admit, with the fondest credulity, the necessary presence of a physical one, even though they can neither exhibit it to others nor see it themselves. But as to asthma, cough, dyspnœa, and other like affections of the respiratory system, they will frequently be found in

nervous and hysterical patients, without any visible source of irritation whatever, and only traceable to the intangible influences of mental emotion. Several of you may recollect the patient Emma Simkiss, who had frequent cough without any expectoration, a pulse of 120, occasional wheezings, and great dyspnœa, so that the respirations were upwards of forty in the minute, though the resonance was clear. She took antimony, digitalis, and ætherated lobelia, after which the pulse came down, and the wheezing and cough diminished, but the frequent respirations remained as before—at 40. Observing her excitability, she was put under the test of the spirometer. After trying again and again for at least ten or twelve times, she seemed able to expire no more than 32 ounces or so; yet, at length, after a deep sigh and a determined perseverance in expiration, she emitted not less than about 96 ounces of air, which of course was decisive as an evidence of the nature of the case. The same observations apply to hooping cough, under the admonitary recollection that it depends on a specific morbid poison, which is apt to induce inflammatory action in the stomach, lungs, and medulla oblongata itself, which shall run a determinate organic course, irrespective of the greater or less amount of the concurrent diaphragmatic and laryngeal convulsion.

OBSERVATIONS ON HYDATID DISEASE OF THE LIVER.

By P. MARTIN DUNCAN, M.B., Londin.,

PHYSICIAN TO THE ESSEX AND COLCHESTER HOSPITAL.

PART II.*

At the conclusion of my last paper it was mentioned that the hydatid consisted of an external fibrous sac, which contains the true acephalocyst which is formed of numerous concentric laminæ, and of a fluid enclosed by these; the echinococci were described, and my belief that the refractile globules which, after a certain age, are apparent within their bodies, are ova, asserted. In the present communication there will be found a description of the development of the secondary acephalocysts and of the echinococci; the method of generation of the primary acephalocysts is dwelt upon, and their distribution and decadence noticed.

The primary acephalocyst, having, in a manner presently to be explained, obtained a position suited for its growth, rapidly enlarges, and developes within itself secondary cysts and echinococci. The two innermost laminæ of the acephalocyst have to do both with the generation and development of the echinococci and secondary cysts.

The innermost lamina, it is to be recollected, is washed on its inner surface by the fluid of the acephalocyst; its outer surface is in apposition with the inner surface of the second lamina. The secondary cysts are developed in the following manner:—A mass of jelly-like substance is deposited from the inner surface of the second lamina; it necessarily causes a projection of the first or innermost lamina, which it separates from the second. In fact, an interlaminar space is formed, which is occupied by the new deposit. Highly refractile molecules soon appear in the deposit, which rapidly becomes opaque and granular. The first lamina is now stretched tensely over the deposit, and becomes more so as this increases in bulk. Clear spaces now form, and the indistinct outlines of microscopic cysts are seen in all parts of the deposit. By rapidly increasing in number and in size, these miniature acephalocysts rupture the first lamina, and escape into the fluid of the parent acephalocyst.

It is to be noticed that the second lamina has nothing to do in this affair, but to throw out the deposit; it undergoes no thickening. The first lamina is rendered tense, and bursts with a rent commensurate with the dimensions of the new formation. Occasionally the cysts grow to a considerable size whilst between the laminæ, and render the parent cyst very opaque in the spots occupied by them. After escaping from the interlaminar space, the newly-formed cysts sink, by their weight, to the bottom of the fluid in the parent cyst, and remain in apposition with the first lamina, whence they draw their nourishment. Growing more or less rapidly, according to circumstances, the secondary cysts become more and more laminated, and soon produce others within themselves. It appears that the secondary cysts, when just developed, consists of two laminæ only, and that the third lamina is gradually produced from the most external by a kind of fissiparous development; the fourth appears to be produced in a like manner from the third, and the fifth from the fourth, and so on. The cysts developed by the secondary cysts are evolved in the same manner.

The importance of the second lamina is very great; it deposits the cyloblastema whence the secondary cysts are developed, and it adds to the size of the cyst, to which it belongs, by splitting, and thus producing another lamina; the echinococci are moreover developed by it in the following manner:—At certain spots the second laminæ undergoes thickening, and at corresponding situations a slight deposit occurs upon its inner surface; the first lamina is slightly stretched upon the new formation. Gradually the thickened part of the second lamina, with the deposit covering it, contracts at the base, and enlarges at the part most remote from the unaffected portion of the lamina, and in a short time quite a change takes place in the position of the tissues. The innermost or first lamina is seen to form a sac, which encloses a mass with a constricted base; this mass consists of a central stalk-like prolongation from the second lamina and of a faintly granular body placed upon this. These projections into the fluid of the acephalocyst sometimes exist in such numbers as to give quite a ragged aspect to its interior. As yet there is no sign of animal life, but after a while the stalk-like

* Continued from page 60, No. III., February 5, 1851. It is as well to have the former number at hand, as it is constantly referred to. The difficulty of obtaining specimens has caused the delay in the production of the paper.—P. M. D.

prolongation becomes covered with a deposit, identical with that it supports; it is in this new deposit that, first of all, little round bodies are seen; they are attached by their bases to the stalk-like prolongation, their free surfaces are surrounded by the granular deposit, and they are kept from the fluid of the parent acephalocyst by the interposition of the first lamina. These round bodies increase in size, their attachment becomes constricted, and in a short time the constricted part elongates into a stalk. The general appearance of the central stalk-like prolongation of the second lamina, with its little stalks, each terminating in a globular body, and the whole surrounded by the investing innermost lamina, is very peculiar.

The granular deposit gradually disappears. Very shortly after the globular bodies become stalked, a line of lighter tissue than the rest appears in each of them, near the centre, and at right angles to the long axis of the stalk; this bright line is afterwards the seat of the peculiar teeth. From a simple globule the echinococcus is thus rapidly developed, the stalk-like connexion between it and the central prolongation of the second lamina gradually attenuates, and finally separates. The sac formed by the first lamina is either ruptured before or immediately after the separation of the echinococcus from the stalk; and these creatures, still in imperfect states of development, pass into the fluid of the acephalocyst, and obtain nourishment by attaching themselves to the walls by their teeth. The fully-developed creature has no projection from its body, the immature echinococcus has the remains of its stalk. As the echinococcus advances in age the bright spots, which I believe to be ova, appear.

In those acephalocysts which have undergone a spontaneous cure, the fluid in which the echinococci float is nearly absorbed, and they will be occasionally found congregated in considerable numbers wherever there may happen to be an excess of moisture. In a case I have already mentioned numerous echinococci in the above predicament were found; they had lost their bright globular spots, and were surrounded by spherical cells with granular interiors.

Although I have been unable to make out the process of development of the echinococci in the secondary acephalocysts, I have no doubt but that it resembles that already described as occurring in the parent cyst.

A patient in the Colchester Hospital, who had had a blow on the loins, and is now suffering from a superficial hydatid cyst, has enabled me to satisfy myself as to the above particulars, and has added to our pathological collection a perfect globular secondary acephalocyst, containing others.

A weak solution of Goadby will preserve hydatids for any length of time, and a good quarter of an inch power is sufficient to distinguish the beautiful laminæ and the echinococci. It is most difficult to explain the method by which acephalocysts enter the system; most probably the ova of the echinococci produce creatures adapted for perforating tissues, and which deposit ova which develop acephalocysts within the structures of the body. We constantly find that entozoa, whilst free and unattached to the creature they are about to inhabit as parasites, differ in external conformation from those of the same species found within the creature. In one class the organs of locomotion and of perforation are successively lost as the entozoon passes into the body of its victim. In fact, the further an entozoon penetrates the simpler does its organization become. So we have some right in asserting, as a probability, that the echinococcus, before and whilst perforating, differs from that which is developed from the tissues of the acephalocyst. Neither acephalocysts nor echinococci have ever been found on the free surface of the body or even on the mucous membranes, but they have been found in the blood vessels, but, of course, subsequent to some perforation. Andral (Clin. Med. ii.,) p. 412, gives the following interesting case:—

A man, aged 55, with all the symptoms of organic disease of the heart, died asphyxiated. Both lungs were found to be filled with a great number of hydatids, which were first thought to be in the substance of the lung, but on careful dissection it was discovered they were all lodged in the pulmonary veins. Andral traced these veins from the heart to the lungs, and on reaching their almost capillary divisions he found that many of them presented a great number of pouches, which were formed by dilatation of a portion of the vessel, and which were filled with hydatids. Beyond each of these dilated portions the vein regained its former calibre, and a little further on became dilated again. The largest pouches were of the size of a walnut, the smallest scarcely as large as a pea. The hydatids had all the characteristics of acephalocysts.

This most important case gives us a clue to the means by which the acephalocysts are scattered about and located in the body; it explains how we find them in the brain, bones, liver, lung, mesentery, kidney, and in most of the tissues of the body; it gives us reason to believe that the germ, from which the acephalocyst springs, is translated from place to place with the blood until it reaches a vessel so small as to check its career. Dilatation of the walls of the vessel is then brought about by the increasing dimensions and consequent pressure of the acephalocyst, and the tissues around begin to suffer, and undergo those structural changes explained in my last communication.

The relation which the echinococcus bears to the acephalocyst, is indeed curious; the fact of a creature producing an offspring totally unlike itself strikes one as being very paradoxical, but the instances about to be given will, it is trusted, be satisfactory. In the distribution of hydatids, the enormous numbers of entozoa, and their ability to withstand external influences, must be held in mind. It is also to be noticed that very few out of the myriads of entozoa that attempt it, fulfil their destiny as parasites; and we must remember that there is a vis in the healthy body which enables the system to repel the attacks of both ento- and epizoa.

One of our greatest comparative anatomists, in noticing the immense number of ento- and epizoa, and the singular capacity they have for resisting destructive agencies, remarks, that in all probability every species

of entozoon has a different manner of entering the system of the animal of which it is to be a parasite. The more one studies the economy of entozoa, the more does the above remark strike the attention, in fact the variety of the methods by which a fragile little creature is enabled to reach a position in an animal larger than itself, where it can fulfil its destiny, is marvellous. Everybody is familiar with the fact that Nordmann*, some years ago, startled the scientific world by announcing his discovery of fifty-eight species of entozoa in the eyes of different fish. Now, Steenstrup made out their method of entrance, and distinctly proved that the chambers of the eye are the only places where these entozoa are fully developed. The life of one of these eye parasites is as follows:—Springing from an ovum a small, soft, and yet active creature, it grows rapidly, and speedily frequents the neighbourhood of the head of the fish it is destined to inhabit; it attaches itself to the cornea, and gradually insinuates itself through its layers, in a direct line, however. Arrived in the anterior chamber, it remains at rest close to the opening it has made, a film forms around it, and thus enclosed, it undergoes a metamorphosis. When this is completed, the film is ruptured, and the true eye parasite is at liberty to range about the interior of the organ. A white streak indicates, for some time after, the line of entrance through the cornea. But if the parasite happens to pierce any other part of the body of the fish, (the external tegument, for instance,) it undergoes metamorphosis all the same, but never escapes from its film; the conditions requisite for its future maintenance do not exist, that is to say, there is no expanse of fluid in which the creature, if perfect, can live after its emergence from its case. Steenstrup has, moreover, traced the path of an amphistomum through the mucous membrane of the rectum of the common frog, and has found it undergoing metamorphosis on the mesentery. He has also demonstrated the entrance of a cercaria into the skin of the common fresh-water snail. He has shown how it is modified in form to suit its new abode, how it pierces all the organs, even the heart itself, and how it lives upon the juices of the gasteropod. At this time of the year any careful observer may, by following Steenstrup's† directions, satisfy himself how thick tissues are pierced by soft entozoa.

It is evident that the structure of the acephalocyst differs from that of the cyst which encloses certain species of perforating entozoa during their metamorphosis. It is to be noticed also, that the ecchinococci are developed from the acephalosyst, and undergo no change. Much impressed with the value of Steenstrup's researches in the generation of the lower animals, I do not hesitate to recommend his book to all interested in natural history, especially as I believe that he gives us the strongest analogies by which we may explain the generation of acephalocysts. The medusæ or jelly fishes which frequent our shores, present in the autumn globular ova within the ovaries; whilst in the ovaries young are developed in the ova. These oval or cylindrico-oval young quit the egg, and are collected into special receptacles formed in the tentacles of the animals, whence, after a time, they escape.

Now, this progeny does not resemble the parent in any one particular; each newly-born creature swims about with the assistance of its ciliary covering, until it reaches a fit place for its future career. A depression now appears at one end of its sac-like body, and this depression soon turns out to be an apparatus by which the body is to be firmly fixed and located. Soon four, then six, then twelve, then thirty and more tentacles are developed from the free extremity of the animal, which then presents every aspect of a polype. Now, this polypiform descendant of a free swimming medusa does not produce ova, but develops creatures from its own body, both by fissiparous and gemmiparous generation, like unto its parent. In other words, a medusa lays eggs, which, when hatched, produce creatures unlike the progenitor, but which, by-and-by, without the interference of an opposite sex, develope medusæ. The cercaria I have already mentioned as attacking the fresh water snail, possesses the following peculiarity of generation:*—After the cercaria has lived for many months, in the water surrounding the snail, it will be noticed that its visits to the creature it is soon destined to inhabit as a parasite, become more frequent. Swimming about for a short time, these cercariæ attach themselves by their suctorial cavities to the snail's integument, so that their anterior extremities and their tails are free. After a while they endeavour to insert their head, and as much of the body as is possible into the mucous integument; they then lash out the tail forcibly from side to side, and at last wriggle it off, and their first phase of existence is ended. The creature now resembles a fluke or distoma, and it could not fail to be recognized as such, in case it were met with in the viscera of other animals. As soon as the tail has been got rid of, the cercariæ, which, during their late violent exertions, have been covered by a thick mucus, begin to turn round and round in a serew like motion, and endeavour to pass through the integument in which they are embedded, and to reach the adjacent organs. It is worthy of notice, that the deeper they penetrate the simpler in organization do they become, that is to say, they gradually lose the suctorial cavity and their skins become thinner, and their spines less distinct. Whether the cercariæ pass through the integument, or remain embedded in it, or simply remain attached by their spines to the outside, in a short time the mucus around them hardens, they beeome quiescent, cast off a thin skin, and surrounded by these as by a cyst, undergo a metaporphosis. Emerging, they after awhile produce ova. The ova produce creatures which bear no resemblance to their parent—creatures which grow rapidly, take on a yellow colour, and which do not produce ova. These yellow beings are to be seen at this time of year in all the organs of the fresh water

* Nordmann, Mikrographische Beilräge Zur Naturgeschichte der Wirbellosen Thiere. Berlin. 1832.

† Steenstrup's Alternation of Generations—Ray Society.

* See Busk's Translation.

snail; they soon begin to develope little circular cells within their integument. Now, these cells are not ova, but become gradually developed into cercariæ, which at last burst the integument and escape. So that the cercaria produces an ovum, out of which comes a creature, the yellow worm, which produces in itself creatures like its parent cercaria, before it had entered the body of the snail.

It is found also, that some of these yellow worms do not produce cercariæ inside them, but creatures like themselves, which in their turn develope cercariæ. This wonderful series of structural changes singularly adapts the cercaria for its abode; and Nature, knowing how few of these entozoa fulfil their destiny, and how many die before they are capable of reproducing others, evidently formed the yellow worm to prevent their extinction. This yellow worm has the same destiny as the fixed offspring of the medusa, they both produce creatures from their own bodies, unlike themselves, but resembling their parents. Steenstrup calls them "Ammen," wet nurses. This remarkable natural phenomenon of an animal producing an offspring which at no time resembles its parents, but which, on the other hand, itself brings forth a progeny, which returns in its form and nature to the parent animal, is seen in many of the lower classes of animals, and has been studied in the medusæ, claviform polypes, salpæ, trematoda, and cestoidea. It is also to be noticed, that in higher animals a peculiarity exists—in aphides for instance. In the spring, male and female aphides are hatched, and the female is impregnated and brings forth eggs; these produce aphides, which, even to the twenty-fourth descent, produce eggs and progeny unlike the parent, without further impregnation. The last eggs of the season produce male and female insects, which in the usual manner contribute to the existence of the next year's numbers. The fact I have wished to establish, is, that it is frequent for certain lowly-organized animals occasionally to produce creatures unlike themselves, which develope others resembling the parent. To suggest that the acephalocyst is an "amme," which develops creatures like those by which it was generated, viz., echinococci, and which, like as the "ammen" of the cercariæ is capable of developing others like itself, or in other words, of producing secondary acepalocysts.

I think that we may reasonably believe that the ovum whence the acephalocyst springs, is the product of an echinococcus, that this ovum is introdrced from without into the system, that when it obtains a nidus, it after a while produces a globular albuminoid cyst, which, if it can overcome the resistance of the surrounding parts, and that natural resistance of the healthy body against all parasites, gradually enlarges, and, when it becomes visible to the naked eye, is called a simple acephalocyst hydatid. During the course of its growth, by its pressure, it produces alteration in the contiguous parts, bones, blood-vessels, nerves, and whatever may be in the way, become absorbed or degenerate into tough fibrous tissue, which forms the protective wall of the hydatid. After a while echinococci are developed in the lamina of which the acephalocyst is formed, they soon pass into the limpid fluid, which gives it form and tenseness, and either float about or attach themselves by their circlet of hooks. The echinococci, when first developed, are elongated shut sacs, of a brownish colour, and possessing the rudiments of the circlet of teeth; they have no markings on their surface. Dr. Budd, in his correct description of the mature echinococci, writes as follows:—"Studded with globular bodies, which, from their refracting light strongly, have, under the microscope, a strong dark outline and a bright centre." I have noticed in my last communication, that these bright globules are ova.

These ova, I believe, produce echinococci modified in external form for the purpose of being able to perforate tissues, and these echinococci deposit in the blood vessels ova, which are the germs of acephalocysts, producing, by gemmiparous development, ova, bearing echinococci. The acephalocyst, once deposited in one of the blood vessels, passes onwards with the current until it is stopped in some capillary, the smallness of whose calibre could not allow it to pass; it becomes stationary, the liquor sanguinis nourishes it, and produces, according to the resistance of surrounding tissues, a more or less rapid growth. In bone, and in the denser tissues, the acephalocyst grows slowly, but in the folds of the mesentery its growth is exceedingly rapid. The walls of the capillary first suffer; becoming distended, (the apertures being soon closed,) they, in all probability, form the innermost layer of the fibrous sac. Subsequently the progressive growth causes absorption of all the soft parts. Influenced by its pressure, the blood vessels and masses of white fibrous tissue by which these are pervaded, remain in a degenerate state, as part of the sac; and in the liver, bile-ducts of no small size, with their cavities obliterated, undergo the same fate. There appears to be no limit to the growth of well-nourished acephalocysts; they attain to their greatest size in the mesentery. Killing by their pressure or exhausting effects, they occasionally undergo an intrinsic degeneration. It is worthy of notice that occasionally acephalocysts are solitary, that is to say, they may attain a considerable size without generating within themselves secondary cysts. There appears to be no limit to the numbers in which acephalocysts may exist in the system, the presence of one alone is indicative of a loss of that power of resisting the entry of parasites which is peculiar to a healthy being; it is therefore not to be wondered at that many are gradually introduced. I totally disbelieve that whilst in the body one acephalocyst can generate others externally to itself; but there is no reason why, if a large acephalocyst bursts into a cavity, the secondary cysts, providing they can be nourished, should not progress and live.

Hydatids very frequently are destroyed by suppuration of the inner layers of their fibrous sac; this may be caused by violence, or by perforation with knife, cautery, or trocar. And it does not follow that the acephalocysts are materially injured; they are to be found entire, floating about in creamy pus and their peculiar fluid, but as a rule the echinococci perish. I have

mentioned that decadence which invariably occurs after a while of the tissues of the fibrous sac in my last communication, and lately whilst satisfying myself on the correctness of some of the above remarks, I had several beautiful specimens of degenerating acephalocysts. The acephalocyst does not appear to suffer any structural change until long after the deposition of that exudation matter within the vessels and tissues of the external fibrous sac, which has been accounted for in the last paper. It is necessary to recollect that the acephalocyst consists of numerous concentric layers, each of which is in close apposition with a layer on either side. In the healthy acephalocyst the layers are in most perfect contact, no fluid even exists between them, but as the supply of nutrient fluids is cut off by the structural changes in the external fibrous sac, so do we notice in many places slight granular deposits between the laminæ. Now these deposits have, as a rule, this peculiarity: they occur between successive laminæ, and each is in the line of a radius, or of an imaginary line, drawn from the most external laminæ to the centre of the acephalocyst, consequently the line of deposit is at right angles to the direction of the laminæ. Generally speaking not more than twenty interlaminar spaces become affected in one of these lines; the deposit is small in the most external interlaminar space, larger in the next, and increases in successive spaces till the tenth or twelfth, when it decreases gradually to the twentieth. These deposits soon undergo a change highly refractile, globules become evident, and after a while the whole mass becomes hard, occasionally crystalline, and destroys, by pressure, the portion of lamina in its immediate neighbourhood. After a while the linear series of deposits is no longer broken by intervening portions of laminæ, but is in perfect continuity, the integrity of the acephalocyst is suffering, and ere long perforation ensues, the fluid escapes, and comes in contact with the fibrous sac, and suppurative inflammation is a natural result. Occasionally the interlaminar deposit is confined to one interlaminar space, and when such is the case it frequently crosses the track of one of the before-mentioned linear series, a crucial mass results. Having thus noticed the generation, development, and decadence of hydatids, the next paper will include the symptoms, diagnosis, prognosis, and treatment of the disease in the various organs usually affected.

October, 1851.

WHAT OUR ASSOCIATION MIGHT DO.

By C. RADCLYFFE HALL, M.D.,
Torquay.

For the "Provincial Medical and Surgical Journal."

No. II.

An abuse to which people choose to submit cannot be put down. It will die only from inanition, when its supporters one by one have dropped off. It is, therefore, quite out of our power to put down any form of quackery; but it is quite in our power to draw the line of demarcation between it and medicine so plainly as to deprive it of all countenance from established truth. Let it stand alone. At our last annual meeting, the Association spoke out strongly and well against the prevalent quackery of the day; but through its individual members it might do much more than this. Observe the anxiety of all quacks to be considered as part of the medical profession. The lower grades—for there are gradations in this—filch the names of our men of eminence; the less vulgar seek our titles; would fain be on terms of professional intimacy; are delighted when an established practitioner will meet them in consultation; send their patients to authorities on a given speciality "for a diagnosis," as one might send an unmanageable horse to be broken in for his own bestriding; in short, they seek to obtain both the profit of the charlatan and the position of the honourable professional man. Let them seek to combine these incompatibles; but let not us assist them in the search. The public are taught to speak of the New System of medicine. They are not aware, as we are, that homœopathy is no *system* of anything, nor that it has no connexion with medicine at all. How should they, so long as we speak of allopathy on the one hand, and of homœopathy on the other?—so long as our eminent men, both Physicians and Surgeons, coquet with homœopathists in high places, speak mincingly of homœopathy in society, and in no respect discountenance it?

There are two reasons why certain amongst us have done this injustice to themselves and to medicine. The first is the "*auri sacra fames*;" and that we may leave undiscussed. The second is, the assumed impolicy towards legitimate medicine of fanning homœopathy into greater notice by illtimed opposition. And this reason deserves consideration.

It is neither judicious nor dignified for a medical man to obtrude the subject of homœopathy upon his patients or in society, any more than the subject of pathology. Neither is it generally useful or becoming to make the public our court of appeal in any form. To decide a question of law, the public must apply to honest lawyers. If they act otherwise, they suffer. To decide a question of medicine, the public must apply to honest men who have made medical truths their special study. Law requires the diligent study of numerous and various facts, and the exercise of sound reason upon them. Medicine requires precisely the same. When a non-professional person has gone through the work, study, and reflection of the lawyer, he is a competent judge of law, not before. When a non-professional person has gone through the work, study, and reflection of a medical man, then, and not until then, is he a competent judge of medicine. We forget all this practically, when we appeal to the mind of the public by discussing medical theories with or before them. It is for the public to inquire from us what in our profession is true and trustworthy. They will respect our opinion so

soon as we are unanimous in respecting it ourselves. They respect a legal opinion. The law is one—or is supposed to be—and an appeal to the *litera scripta* is decisive. Our *litera scripta* is Nature; a book more difficult to read correctly, unintelligible to the many in proportion to its difficulty, but unexceptionable and all true when it is read. Every special chapter is sealed to all but the special student, and the amount of the ignorance of others concerning its contents, must be unknown to every one but him. It is quite impossible, therefore, for unprofessional people to realize their own utter ignorance of medicine, and consequent incapability of arriving at a just conclusion on theoretical medical questions. The loosest analogy is enough to mislead them. They are asked why doubt the power given by rubbing to a decillionth of mercury, when you see the power of friction to elicit electricity? Or, why question the efficacy of infinitesimal particles of matter, when mental emotion, which is no matter at all, can shock or kill? Or, why deny the transmuting efficiency of the minutest particle of medicine over the condition of the blood in therapeutics, when an inappreciable quantity of contagious matter can derange the entire economy? And what answer have they ready? Ignorant of the facts in point, but acquainted with those which erroneously seem to appertain;—ignorant of the laws of physiology of either body or mind;—unaccustomed to weigh evidence in scientific questions in the same scales which they employ in the routine of life, the only scales they or any one ought to use;—bewildered by the charm of mystification, and pleased with the newness of ideas, so fresh and strange, non-professional persons may be smitten with the theory, or the several theories of homœopathy, without any grave disparagement to either their character or their judgment. It is not, then, to them we can with advantage expose the fallacies of homœopathy in theory. But shall we, therefore, pass by a question honestly asked, in silence, or worse? Shall we answer with a yea, yea, or nay, nay, when asked our opinion on the subject? If we do so, can we wonder that the public suppose homœopathy to be really medicine, but in a new and improved dress? and suppose, moreover, that we ourselves are really of that opinion but will not own it? We should avoid the possibility of this mistake. We cannot, it is true, say anything that will convince the impressionable, who have seldom any convictions upon anything; or the prejudiced, who rejoice in their bigotry; but we can clear ourselves from all suspicion of agreeing in their views. We can, without using uncourteous language, render it quite clear that we are obliged to consider all homœopathists as a distinct class, having nothing with us in common; that whilst we can make no reflection on a non-professional person for espousing homœopathy, we can find no excuse for a professional one. A student to whom the truths of medicine have been disclosed, cannot shut his eyes to them except wilfully. Either, then, a homœopathist has never gone through the labour required to learn these truths, or else he wilfully ignores them. Upon ascertained facts there can be no difference of opinion. No one disputes that a pound of black paint will make a certain extent of surface black. If then, some one declares that a decillionth of a grain of black paint will make the same extent of surface *blacker* than the entire pound, we consider either that he is ignorant of all the truths connected with the subject, or that he is unable to appreciate truth when he has it; or that he has something to gain by differing with his Fellows and with experience. Especially when the apple of his new tree of knowledge is a gilt one; when his espousal of what others reject happens to be fashionable and profitable, we are usually right in concluding that of the common two-horned dilemma which suggests itself, such an one is not the fool.

If we cannot, without much self-restraint, discuss calmly and seriously amongst ourselves the theories of homœopathy, any more than we could calmly discuss maniacal illusions if presented to us as scientific doctrines, it is still more trying to discuss them with non-professional persons. Probably it is never useful, and therefore seldom desirable to do so. A simple denial of all credence in them, and of their analogy to any real facts in physics or physiology, which is the plausible ground of reasonableness generally put forward, is all that is necessary. But the main point in consideration is—the facts. Ask a homœopathist to furnish one *fact* capable of being proved to an unbeliever. Ask him to do by homœopathy anything that is visible;—to clear away the lymph in syphilitic iritis, as medical treatment will clear it away;—to remove purulent ophthalmia;—cure a varicose ulcer, stop a phagedænic one;—cure severe ague, or severe delirium tremens, or congestive apoplexy, as completely and as soon as medical treatment can;—or, at all sooner or more effectually than nature, favoured by hygiène, but unaided by medicine, does. Homœopathists keep the visible in the back ground.

In like manner, when a patient mentions having heard that Dr. Globularius has cured ninety cases of croup, without losing one, in the course of the winter, in a locality where the disease is rarely to be met with at all; or, has succeeded in preventing scarlatina in all of the families he attends (who have escaped the epidemic); or has "stopped" typhus fever from pursuing its course in eighty-six cases in three months; it may be well to explain to the narrator why these statements cannot by possibility be correct.

In the proper way, and at the suitable opportunity, every member of our Association might say a word in season in regard to homœopathy. To fear the impolicy of so doing, is to doubt the prerogative of truth. She will support us, if we never fail to maintain her.

There are some homœopathic practitioners who avow their disbelief in the infinitesimal doses, but adopt the name of homœopathist because they see some truth in the doctrine of "*similia similibus curantur.*" And, apart from the rest, this doctrine, when used with considerable latitude of meaning, is in many instances true enough. In chronic diseases we habitually select as remedies those drugs which specially act upon the diseased organ, and which, by so acting, induce in it some

manifest departure from its ordinary condition. As a result of this alterative influence, the organ will sometimes cease to pursue its morbid mode of nutrition, and by degrees will regain its normal one; in other words it will be restored to health. Now, as all such alterative remedies are abnormal stimuli to the organs on which they act by preference, we should expect to perceive when they have been administered for a sufficient period to a person in health, some departure from normal nutrition in the particular organs in question. And so it is. Mercury, for instance, in a healthy person, will often *produce* a cutaneous eruption. And mercury will *cure* many varieties of cutaneous eruption. The same holds good of iodine, sulphur, and arsenic. Here, then, the remedy will remove in disease that, which in health it will produce. So far we have an illustration of *similia similibus*. But this knowledge is as old, at least, as Paracelsus—who was in some respects, intellect excepted, a very fit representative of Hahnemann—and is and has been constantly acted upon by honourable medical men A man needs not to become a homœopathist in order to believe and practise this. Is this, then, all that *similia similibus* signifies in the jargon of the craft? It is all that can be proved to be true.

Does mercury occasion precisely those forms of cutaneous diseases which it can cure? By no means. If it did it would produce almost the entire catalogue. Can it produce psoriasis gyrata, or herpes circinnatus? To remove chronic diseases of the skin, remedies are useful which act upon the nutrition of the skin. If they can do this in disease, they can do the same in health; and in health they will manifest their action by *some kind* of outward sign—some kind of blush or eruption. But these same remedies will cure *many other kinds* of eruption than the one they give rise to in a healthy person. Hence, the expression *similia similibus* is a very loose one, even when applied to its pattern-examples. But whether precise or vague in its signification, to how few of the facts of therapeutics is the expression applicable at all. The homœopathists make it the one ruling principle of all their treatment (we mean they *profess* to do so) of all diseases. When congestion of the brain is relieved by purging, plethora by abstraction of blood, iritis by the action of mercury, or when hæmorrhage is checked by turpentine, flux by acetate of lead, is there any resemblance whatever between the effects which the remedies can produce in health and do produce now, and the morbid conditions which they remove? To deny the facts would falsify experience; to ascribe them to the principle of *similia similibus*, or *to any other one single principle* would be to stultify the judgment.

An universal doctrine in therapeutics that shall be applicable, without exception, to all diseases, is a sheer impossibility. A law can only be universal in its strict application so long as its subject consists of two elements, and no longer; any third element introduces exceptions which neutralize the law. Thus the law of gravitation is unmodified only so long as matter in a passive condition and space, are the constituent elements of the problem. Add a third element in the shape of force, such as heat, elasticity, &c., and the influence of gravitation is modified, opposed, and, it may be, virtually overcome. If this be so, that a law is only conditionally universal in respect of inanimate matter, how much more certainly will the more complex and numerous elements of a living system preclude the possibility of expressing the sum of their operations in any one form of words. And what is a general principle, a doctrine or law of nature, but the expression of the essential truths of the subject in the fewest words.

Does *similia similibus curantur*, if we admit its truth in a vague sense in regard to some of the facts of therapeutics, explain *all*, or even *most*, of the ascertained truths of the practice of medicine? Not a tithe of them. It cannot then be an universal principle of medicine. So far as it is true, it is old and constantly carried into effect. The man who adopts homœopathy, *minus* its infinitisimals, for the purpose of practising according to this tenet of *similia similibus*, does so practise only where he would have done it before. He treats the great bulk of his cases by the means which experience has sanctioned, whether they agree with his principle (medical) or not. He chooses to assume that all such successful treatment accords with his adopted doctrine; but he knows that he cannot prove it. Does he ever believe it? Would he believe any doctrine in science which could bring no profit with it on similar evidence? If not, the adoption by him of the name of homœopathist can proceed only from contemptible motives. Let every such renegade be held by every member of our Association in the contempt he merits.

There are two occasions on which we provincial practitioners may, with propriety, exercise whatever influence we possess in giving patients a proper bias. In recommending a medical attendant during an occasional residence in town, we ought scrupulously to avoid suggesting the names of all who have coquetted with the homœopathists. Let us, as far as possible, dissuade patients, if so inclined, from consulting these men, and refer them to others who have always maintained what is due to their own position and to their profession. There can be no difficulty in learning of the magnates in our profession "Who is who, in 1851?" The *Lancet* will, doubtless, supply those who require it with a list for their guidance and avoidance.

Secondly, in cases where more than domestic hydropathy is suitable, desirable, and desired by the patient, we may generally prevent him from applying to establishments kept as water-hospitals by omnivorous dealers in homœopathy, mesmerism, and cold water. But on this, and on several other points touched upon in these papers, little needs to be added to the admirable remarks on "Orthodox Medicine," published at page 393 of this journal.

Hospital Reports.

BRISTOL ROYAL INFIRMARY.

SURGICAL CASES ADMITTED UNDER AUGUSTIN PRICHARD, ESQ., SURGEON TO THE INFIRMARY.

Case X.

Gun-shot wound of the Hand.

Joseph Pierce, aged 22, was admitted under my care on the 17th of September, 1850, having just received a severe wound of the right hand. He had been quarrelling with the owner of some quarries about some trespass, when the latter fetched his gun, and taking a deliberate aim, fired at him. They were standing about five yards apart, and Pierce suddenly lifted his hand to protect his face and head, and received the entire charge in the palm, as if he had caught a stone or a ball thrown at him. Not a single shot seemed to have passed beyond his hand.* There was no great hæmorrhage, but a general swelling of the dorsum of the hand, and a hard projection opposite the proximal extremity of the metacarpal bone of the ring finger, as if the end of it was thrown backwards from its articulation with the carpus. My little finger passed readily into the wound at the palm of the hand, and appeared to reach the dorsum without encountering any broken bone; shots were to be felt all around, and the tissues appeared much cut up. He retained the power of slightly moving each finger. The pain in the hand, arm, and shoulder was described as being intense. The hand was placed in a poultice, and an opiate was given him.

18th.—The hand is more easy, but very tense upon the dorsum.

19th.—His arm was placed on an inclined plane, and the swelling soon began to lessen. The swelling at the back is the charge of shot. The skin of the palm being free from the gunpowder, the wound in the centre can be seen, surrounded by innumerable small points or holes, where the shot, just beginning to spread one from the other, perforated the skin of the hand. Two days afterwards I made a free opening in the back of the hand, and gave exit to a few shots. The constitutional symptoms have almost subsided.

23rd.—More shots escaping; very fœtid pus escapes at each wound. Flexor muscles of fore-arm seem to be contracting; to have the arm placed on a splint. From this time he slowly mended, until the middle of October, when the hand became much worse, the external wound having partially healed, there was not sufficient escape for the pus. I therefore made another incision on the back of the hand, and subsequently another on the anterior surface of the wrist, where a collection of matter had formed. As soon as the abscesses had fully emptied themselves, and the wounds looked clean, they were dressed and bandaged, and he began to regain the use of his fingers. He was made an out-patient on the 19th of November, after which I saw him twice. He has collected about one hundred shots from the hand. The powers of motion are gradually being restored, and it appears likely that he will have a useful limb.

* The old man who fired the shot died after a week's confinement in prison.

Case XI.

Gun-shot Wound of the Hand; Tetanus; Recovery under the use of Cannabis Indica and Stimulants.

Benj. Brock, aged 17, admitted on Sunday Aug. 3rd, about 7 P.M., having just received a severe wound in the left hand from a gun, his hand being upon the muzzle, and the gun charged with powder, paper, and probably with small stones.*

There is an irregular wound between the metacarpal bones of the second and third fingers, with exposure of the flexor tendons. The soft parts are much burnt, and the tendons rough. Posteriorly a considerable flap of skin is turned back, the extensor tendons exposed, and the same burnt opening exists between the metacarpal bones. The middle finger is much lacerated, and the veins between it and the forefinger entirely and clearly dissected out, and black. The hand smells of burnt flesh. He suffered intense pain, and an opiate was ordered. It was determined in consultation to adopt nothing in the way of operation. Turpentine was applied to the hand. In three days the flap of skin upon the dorsum of the hand sloughed; it was poulticed, and he was ordered a pint of beer.

7th.—Considerable fœtid discharge from the wound. Lot. Sodæ Chlorinatæ. From this time the wound gradually became cleaner, and among the sloughy matter discharged was the paper wadding of the charge. Granulations very flabby. Zinc lotion ordered to be applied under the poultice.

15th.—The greater part of the middle finger sloughing, I therefore removed it at the middle of the first phalanx with a bone-nipper; a part of the tendinous tissue was divided by the scissars. The bone bled rather freely. A large quantity of pus is daily discharged. To have two pints of beer daily.

29th.—Complains of soreness of the tongue, which he bit once or twice involuntarily in his sleep about a week ago. He states that it first happened in the night of the day when I removed the finger. Upon telling him to put his tongue out, he opens his mouth about three-fourths of an inch, with great difficulty. He always had an impediment in his speech, and formerly used to walk in his sleep. He says that he has had a stiffness of the jaw for some days, but did not think it worth mentioning, except that he was laughing with the other patients, saying that he had lock-jaw, without having any suspicion that he really had it. Bowels confined; hand looking quite healthy. Pulv. Cathart. statim.

30th.—Bowels well opened; muscles of the face and

* This uncertainty depends on the contradictory statements of himself and companions. He says there were no stones. They say that after he had put in the powder, and left the gun in the hands of the other boys, they put in a quantity of small stones.

abdomen very stiff; he is occasionally seized with spasms, which draw him backwards. To take Tinct. Cannab. Indic., in camphor mixture every two hours.

31st.—Profuse sweating, and intense stiffness; pulse very rapid. In the evening he was very much worse, almost sinking under the spasms of the muscles, and the sweating. He was ordered sherry *ad libitum* during the night.

September 1st.—Revived by the wine, of which he took twenty-eight ounces during the night. Enema Cath. statim. To go on with the wine and the Indian hemp.

2nd.—Not quite so well, being in a constant state of spasm. To take the Indian hemp every hour, and the wine in the intervals. Bowels confined, the injection not having acted. Tongue foul. He is able to open the teeth just enough to enable me to see his tongue. Is in as much perspiration as before. The abdomen as hard as a piece of board. To take a minim of croton oil every four hours.

3rd.—Took two doses of croton oil, which acted freely. He appears relieved, and says that he is better. He is extremely stiff, so that when he is moved from the bed, to be cleaned, &c., (one man taking him by his shoulders the other by the heels,) his body does not bend at all, but remains perfectly rigid. Sweating and exhaustion extreme; pulse very rapid. To go on with the Indian hemp, but to take in addition, as a draught to-night, eight grains of quinine, half a drachm of dilute sulphuric acid, and twenty-five minims of liquor opii sedativus, in an ounce of water.

4th.—Has passed the best night since his attack, and is obviously better, but still as stiff as a board. To take the medicine as before during the day, and have the quinine draught at night.

5th.—Better. To leave off the Cannabis Indica, to take a quinine mixture and to go on with the wine and beef-tea.

8th.—Hand looking well. The spasms of the muscles have subsided; he has had but little of it for the last two days; bowels confined. Ol. Ricini., oz. ss., stat.

9th.—He refuses to take any more quinine. Has had a return of the spasms of the muscles of the back, limbs, and throat. He was in a state of great alarm last night from the difficulty of breathing brought on by the spasm of the throat. To return to the Cannabis Indica, which he says he likes, for it relieves the muscular contractions.

10th.—Better. To take the mixture every two hours.

11th.—Can open his mouth now about three quarters of an inch. Asked for beer instead of the wine. To have two pints of strong beer daily.

12th.—Appetite good; tongue clean. The muscles of the face and abdomen are still rigid. He cannot stand, from want of power to balance his body and to guide the limbs by his will. He can, however, lie on his side, and draw up his legs a little. Has had no spasmodic contraction since the 10th. To take his mixture three times a day.

He took thirteen bottles of wine from the 31st of August to the 10th of September—*i. e.*, in eleven days.

16th.—To sit up, and leave off all medicine. Legs still too stiff to allow him to stand, although he can sit. Abdomen and face rigid. Opens his mouth rather better.

18th.—Is able to walk about a little. He cries out and moans in his sleep, as he did during the height of the spasms.

October 6th.—Has been improving daily since the last report. He can open his mouth freely; but there is still an unnatural contraction of the muscles of the face. He was discharged with the wound almost healed, the fore and ring fingers being perfectly stiff. He can move the little finger, and touch the tip of the thumb with it.

Case XII.

Disease of the Cranial Bones and Abscess of the Cerebellum, following an Old Injury of the Head.

A bargeman aged 26, who received a severe injury from a fall on the back of the head nine months ago, was admitted on the 17th of April, 1851. Three months before admission he began to suffer from headache and throbbing. There is a scar of rather more than an inch in length on the upper part of the occipital region. The back of the scalp is much puffed and swollen, and very tender to the touch. He complains of the pain and uneasy throbbing much below the position of the scar. He has little or no sleep by night, and has an anxious desponding look. He was ordered leeches to the scalp and some purgative medicine, and after two days he began to take five grains of blue pill three times a day.

With this plan he persevered until the 28th, when the mouth became sore, and sarsaparilla, with iodide of potassium was substituted for the mercury. I proposed to make a longitudinal incision and issue in the scalp, but deferred it, as there was a case of erysipelas in the ward. He was therefore occasionally leeched, and on one occasion an opiate was ordered, as he complained so much of want of sleep, but without any good effect.

On the 21st of May the issue was made, and was followed by a decided and immediate improvement for a short time, after which he relapsed into his former condition.

On the 15th of July the portio dura of the seventh nerve was suddenly paralyzed upon the right side, with all the usual symptoms of inability to close the eye, &c.

July 21st.—The portio mollis of the same side became similarly affected, and he was entirely deaf with this ear. Now the diagnosis became more precise; for although it was obvious before that there was disease of the dura mater or bone within, resulting from the injury, yet it now became clear that there was some morbid product actually situated at the base of the brain pressing upon the seventh nerve, either at the side of the cerebellum or at the entrance to the internal auditory canal.

24th.—He has been vomiting occasionally for the last

day or two, and for this a Prussic acid mixture was ordered. After a consultation with the physician the issue was enlarged by means of caustic potash.

August 4th.—Great difficulty of swallowing, depending without doubt, as did the vomiting, upon affection of the par vagum. He never had any paralysis of the limbs, but he gradually became weaker, and died on the last week of August, having been comatose about twenty-four hours before his death.

Post-mortem examination.—The upper surface and substance of the cerebrum were healthy. Upon dividing the tentorium and removing the cerebellum, an abscess in the right hemisphere gave way and discharged about two drachms of pus; it was situated between the grey and white matter, encroaching upon both. Parts of the cerebellum were adherent to the fibrous covering of the temporal and occipital bones. There was an effusion of fibrin, infiltrated with pus, in a mass as thick as the finger, along the inner crest of the occipital bone, and in the right lateral sinus, and a considerable quantity of pus was between the dura mater and the bone. The edge of the foramen magnum was carious, with pus on the surface, as far as the temporal bone anteriorly. The occipital bone was much softened and rough over the lower part, and was easily perforated by the point of a scalpel. There was also pus among the muscles of the neck.* He had never had syphilis.

* About this time the following case occurred to me, in what may be called "private practice." Among some chicken which I was rearing behind my house, was a young cock with a little "game blood" in his veins, which, when about eight months old, attacked his progenitor, a fine bird of the Polish breed, and, after a morning's fight the young one was victorious, and the old one was found almost insensible, and lying under the wall, with his head bleeding severely. I applied cold affusion and had him watched and nursed, and in a few days he was convalescent, when he renewed the contest, and ultimately remained master of the field. About two months afterwards I observed that the old bird had ceased to crow, that his wings drooped, and that instead of strutting about as heretofore, he was crouching most of the day on the grass; I therefore had him nursed again, and he improved, but a day or two afterwards he was found dead under the roost, having (from the position of the limbs) evidently died before he fell. His head was cut off, and I intended to make an examination of it, but neglected it for want of time, until it was too late, and therefore I simply placed it in water to make a preparation of the skull, as I am in the habit of doing. Upon cleaning this skull a few days ago the cause of death was obvious. He had had fracture of the upper portion of the cranial bones and caries of the edges of three or four openings, which exist in it, and I have no doubt that there was suppuration within for the bone appears a little thrust upwards as if by some growth or effusion in the interior.

Provincial Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 26, 1851.

The Central Council of the Provincial Medical and Surgical Association desire us to announce, that they have, with the sanction and concurrence of the Manchester Council, been led to alter the place of holding the Anniversary Meeting in 1852, from Manchester to Oxford, and it appears to be due to the members of the Association, to make a statement of the circumstances which have led to the change.

Soon after the Brighton meeting, which was held in August, the President of the Council received a pressing invitation from the late lamented Dr. Kidd, for the Association to hold an early meeting at Oxford, as it was his strong desire to witness another gathering of the Members in Oxford before his death, and as he could not naturally expect his life to be spared much longer, he was induced even to hope that the Manchester Members might not object to wave their claim for 1852, in favour of Oxford. This wish, expressed by Dr. Kidd, was communicated to the Manchester Council, who very kindly passed a resolution to the effect, that under the circumstances of Dr. Kidd's advanced age, they would give up their right to have the Anniversary Meeting held in Manchester, in 1852. Whereupon the Central Council passed a resolution appointing Oxford as the place of meeting for that year, and in conformity with the nomination of Dr. Kidd, Dr. Ogle was appointed President-Elect, instead of Mr. Wilson, of Manchester.

This arrangement was scarcely completed, when Dr. Kidd was suddenly removed by death from the scene of his exertions, and the question was then again forced on the Central Council,—Whether the meeting should be held in Manchester or Oxford? Dr. Ogle and the members of the profession at Oxford, most handsomely came forward, and whilst they expressed their desire to have the meeting at Oxford, intimated that they were anxious for the welfare of the Association, and would be guided by the wishes of the Council. A reference therefore was again made to the Manchester Council, who concurred with the Central Council, that the meeting for 1852 should be held in that ancient seat of learning, the University of Oxford, and that Dr. Ogle, who has been appointed Regius Professor of Medicine, be the President-Elect.

We had hoped that the melancholy case in which Dr. Murphy met a homœopathic practitioner at Norwich, would have been the last instance of so unholy a compact which we should be called upon to notice. It is, therefore, with unfeigned regret that we are in a position to inform our readers that Dr. Holland, a Fellow of the Royal College of Physicians, has so far forgotten his professional *devoirs* as to have

met in consultation this identical Mr., or Dr. Bell, which ever he may be. That he has done so we have the word of a highly-respectable practitioner in Norwich, who unavailingly endeavoured to prevent Dr. Holland from committing himself, by telling him the exact character of the person whose patient he was called upon to visit.

We are informed that a meeting of the Norfolk and Norwich Hospital staff took place, to take into consideration this extraordinary conduct on the part of Dr. Holland, and that they in strong terms expressed their disgust, that while no physician or surgeon can be found in that city who will disgrace himself by meeting a homœopathic practitioner, physicians of eminence in London appear to have no scruples in doing so.

Whether Dr. Holland can find any excuse for this dereliction of professional duty, we know not, if he can we shall be delighted to give his explanation equal publicity with the present notice.

Proceedings of Societies.

GLOUCESTERSHIRE MEDICAL AND SURGICAL ASSOCIATION.

Copy of the proceedings at the Quarterly Meeting held at Cirencester on the 9th of October, 1851.

The minutes of the proceedings of the last meeting were read, and also an article in the *Lancet* of August 2nd, 1851, in relation to those proceedings.

The Secretary stated that he had several letters from members who were unable to attend, which he proposed to read, when those points were brought under discussion to which the letters referred; that one of them being applicable to the present stage of their business, he would proceed at once to read it. He then read part of a letter from Mr. Rumsey, of Gloucester, which concluded with recommending a resolution to the meeting. The Secretary said as Mr. Rumsey was absent he would himself propose the resolution, as it met his entire approval.

The resolution being read, Mr. Watts, of Frampton, and Mr. Goodlake, of Painswick, immediately rose to second it.

Mr. Warner, of Cirencester, suggested some verbal alteration, which was acceded to.

Dr. Collings Robinson inquired whether Mr. Stokes, the late President, to whom the resolution applied, was a homœopathist.

The Secretary answered in the negative, and stated that in one of his letters which he held in his hand, to read as the business of the day advanced, Mr. Stokes distinctly says, "I am no homœopathist."

The President then put the resolution, which was carried unanimously,—

"That our late worthy President, not having fully completed the period of his services at the time when the vote of thanks was passed to him at the last annual meeting, the Association regrets that in the discharge of the concluding duties of the day he should have been exposed to unjust and hasty censures with respect to the resignation of Dr. Adrian Stokes; and they feel assured that those censures could have originated only from an imperfect knowledge of the facts of the case, and of the objects of the Association, and that this meeting desires to record its entire approval of Mr. Stokes' conduct as President, and its thanks for the interest he uniformly manifested in the welfare of the society."

Dr. Collings Robinson then addressed the meeting on the resolutions, of which notice had been given by Dr. Brookes; he expressed his regret that Dr. Brookes should not have been present, and stated that he had undertaken on behalf of Dr. Brookes, whose professional engagements caused his absence, to bring the resolutions before the meeting. He declared his full approbation of the principles of those resolutions, although he liked those framed by the Council of the Medical Society of London, better; he would, however, submit to the meeting those of which notice had been given, and after urging the necessity of their adoption, he proposed the first, namely:—

"That the reporters for the medical journals be eligible for admission to all meetings."

It was observed by several members that the eligibility of reporters for admission had never been doubted. Mr Wilton said that they had been admitted whenever proposed, and were always considered admissable when the members present desired it.

On this representation Dr. Collings Robinson abandoned this resolution, and proceeded to propose the next, namely:—

"That there are three classes of practitioners who ought not to be members of this Association:—1st, real homœopathic practitioners; 2nd, those who practise homœopathy in conjunction with other systems of treatment; and, 3rdly, those, who under various pretences meet in consultation, or hold professional intercourse with, those who practise homœopathy."

After some pause, the President inquired whether any gentleman would second the resolution just moved? No answer being returned, after some further time, the President said,—"As Dr. Robinson's resolution is not seconded, it is lost."

The letters received by the Secretary on the subject of those resolutions were, therefore, not read; and immediately on the President's decision, Dr. Collings Robinson handed to the Secretary copies of three resolutions, which he said he should bring forward at the next meeting at Cheltenham. The following is a copy of them:—

1st.—That the practice of homœopathy, or the prescribing medicines in what are called "infinitesimal doses," under a pretence that they are useful in the cure of disease, is founded in palpable error, is a delusion on the part of the practitioner, a deception on the public, and manifestly dangerous to its welfare.

2nd.—That the members of this Association cannot honourably hold any professional communion with homœopathists.

3rd.—That, consequently, any member of this Association who shall hereafter practise homœopathy, or who shall knowingly meet in consultation any professional homœopathist, will thereby render himself unworthy of the membership of this Association.

Foreign Department.

PROCEEDINGS OF THE FRENCH ACADEMIES.

ACADEMIE DE MEDECINE.

The last few meetings of this Academy have been almost without interest, if we except one at which the subject of *congenital syphilis* was revived by the relation of an instructive case by M. Paul Dubois.

A young woman, aged 19, was admitted into the Obstetric Clinic in the seventh month of pregnancy, having symptoms of secondary syphilis, as roseola, sore-throat and mucous tubercles. She was delivered on 7th of August of a small but lively infant, which had several round red patches, one on the plantar aspect of the left foot, and another on the ankle. Next day similar patches appeared on the upper extremities. While the fresh patches were coming out, the older ones gradually developed into perfect bullæ of pemphigus. In spite of the most assiduous attention the child gradually shrunk away, and died. This case gave rise to a discussion in which the old arguments were produced, (*vide Provincial Medical and Surgical Journal*, No. xxii.,) and which we will not, therefore, again allude to.

M. Latour read a paper on the "*Therapeutic Processes, the Action of which resembled the Action of Impermeable Varnishes on the Skin.*" In this essay the author reviews the various topical applications in general use, and shows their analogy to impermeable varnishes. Among these he mentions plasters of various kinds; unguents, as mercurial ointment, liniments, and oils. He also cites in further illustration, Velpeau's and Dr. Seutin's starch-bandages in the treatment of fractures; the utility of these he considered to be due, in part at least, to the effects of the exclusion of the air in preventing or subduing inflammation.

The benefits that have been supposed to be derived from compression in certain local inflammations, *e.g.*, orchitis, M. Robert-Latour considered to be owing to the impermeability of the dressings.

The dressing of wounds by occlusion, and the advantages of subcutaneous incisions, the author also regarded as instances of the benefits to be derived from the prevention of the contact of air with inflamed surfaces. The essential and initial phenomenon of inflammation, according to M. Latour, consists in the exaggeration of animal heat in a more or less circumscribed space, while the redness and swelling are but the result of dilatation of the blood globules, the inevitable physical consequences of this increased temperature. Observing the rapid reduction of temperature in parts covered with an impermeable varnish, the author had come to the conclusion that the action of the air on the skin is an indispensable condition of the calorification, and therefore, to be rational, the treatment directed against inflammation should be that which attacks the very source of the disease.

M. Robert-Latour concluded by pointing out the objections and difficulties attending the application of collodion, and stated that these may be obviated by adding a fifth part of its weight of turpentine deprived of its essence by evaporation, and five or six drops of castor oil in thirty grammes (= about seven drachms, Eng.) This combination forms a varnish, which, without losing its impermeability, acquires a suppleness and elasticity which is wanting in ordinary collodion.

Arsenical Poisoning.

A very interesting case has recently come before the French Tribunals, in which the question arose, as to the possible contamination of a corpse buried in an arseniferous soil. M. Barse, who was ultimately consulted, appears to have shewn more than ordinary toxicological acumen. (*Union Médicale*, September, 1851.)

A man and his wife were accused, the one of poisoning his former wife, the other her former husband. Both coffins, buried in different cemeteries, were exhumed. The female was in good preservation, the coffin being intact; the male less so, the coffin being much decayed and earth being found within it. Arsenic was found in both bodies, but the surrounding earth in both cemeteries were found to contain arsenic also. The chemists were puzzled, but from the fact that in the coffin of the female no arsenic could be detected in the cerements or other matters interposed between the corpse and the earth, they concluded that it was a case of poisoning.

M. Barsa being appealed to, decided that this was the correct opinion, as the native arsenic in the soil was always mixed with iron, cobalt, or antimony, and could not be detected by ordinary reagents. Its insolubility would also prevent its reaching the bodies by filtration. To confirm this view he likewise examined other bodies buried in the vicinity of the two in question, but no arsenic could be detected. He further searched the chamber in which the man died, and finding splashes on the walls and on the floors, which indicated the vomitings of the patient, had the spots scraped carefully, as also other parts of the room distant from the bed. The former matters contained arsenic, the latter none. The parties, on this were found guilty.

A Clay Pipe Swallowed and finally ejected per Anum: Death.

M. Gosselin, a few days ago, brought before the Surgical Society of Paris the following extraordinary case:—A man, thirty years of age, of a pretty strong

constitution, had of late made it a trade to swallow various objects for small remunerations. About two months ago he wagered that he would swallow a clay pipe; the latter was of the ordinary size, about three inches and a half in length; it had only been smoked four times and contained no tobacco. The wager was taken, and the foolish man won it. He had no difficulty in swallowing the foreign body, but as soon as it had reached the stomach, severe pain was felt, and vomiting and diarrhœa came on.

The patient sought relief at the hospital of the town of St. Germain, but he obtained no relief during the fortnight he stayed in that institution. He was now advised to go to Paris and was admitted into the Hôtel Dieu, where M. Gosselin tried in vain to put a stop to the vomiting and diarrhœa. The man was becoming very weak, and looked very much like a patient dying of phthisis; the tongue was red and dry, and the sickness recurred five or six times a day. M. Gosselin felt very much embarrassed. In consulting systematic writers, he found that Hevin had removed foreign bodies from the stomach by the operation of gastrotomy; but as to the method to be followed when the foreign substance is lying in the intestines, he discovered only a few precepts but no facts.

By careful percussion with the plessimeter, dulness was discovered in the right iliac fossa over a space of about two or three inches; no gurgling or tumour was observable on the spot, and it was very probable that the pipe had reached that region. On the next morning this dulness had disappeared, and in the course of the same day the clay pipe was evacuated per anum, quite intact, with the tube unbroken. The system had, however, been very severely tried, and the patient sank five days after being freed from the foreign body. No trace of redness or congestion was found in the stomach or the small intestine, but in the colon numerous ulcerations were observed, some quite recent, and others completely or almost cicatrized. Membranous exudations covered the convex surface of the liver and the inferior aspect of the diaphragm. In the chest, traces of pleurisy and pneumonia were discovered.

On Relaxation of the Symphysis Pubis after Labour.

It is not an uncommon occurrence after delivery, to find relaxation of the pubic ligaments; but from the uncertainty of the symptoms developed by it, it is liable to be mistaken for disease or displacement of the womb. M. Marten, (*Gazette Médicale*, Juliet,) hopes to throw some light upon the subject.

In all patients suffering from this affection, standing is peculiarly painful and difficult, so that the patient can barely walk a few paces even with the help of crutches. They also complain of more or less dysuria, with frequent micturition. If the hands are placed on the ilei while the patient attempts to walk, he will find that the hip of the leg which rests on the ground is pushed up, while the opposite, from contrast seems lower than natural.

In treating this accident, M. Marten makes use of a steel girdle, which entirely encircles the pubis. By means of the support thus afforded, he has known a patient walk with ease, who a few days previously could with difficulty stand upon her feet.

Speedy Cure of Drunkenness.

In the *Abeille Medicale* M. Lalaux mentions a novel, and, according to him, unfailing way of dissipating the effects of alcohol, viz., enemata of common salt. Among the most remarkable cases he narrates are the following:—

In 1840 he was summoned to three youths who were said to be dead drunk. He found the most complete relaxation of the limbs, with total insensibility, cold extremities, livid countenance, and stertor. A clyster of salt acted like a charm, and in an hour they were able to walk without staggering.

The effect of the enema is to produce copious stools.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

Why is a true Corpus Luteum formed only in cases of Impregnation?—By Dr. Alexander Harvey.

Taking it for granted that the assumption is a true one that a *genuine* corpus luteum does only occur in impregnation, though a *false* one appears after each oviposit, the author seeks for a reason, and finds one in the following explanation:—

1. When a mature ovum is impregnated, provision is forthwith made to retain it in utero, and both ovum and uterus became the seat of active vital processes, which cause a prolonged determination of blood to the reproductive organs. The ruptured ovisac participates in this afflux, and the organizable deposit which it contains is placed under circumstances favourable to the exercise of its inherent powers of growth, and thus it becomes developed into a true corpus luteum.

2. On the other hand, when the ovum is not impregnated, it is thrown off in the menstrual discharge, no prolonged afflux taking place as in the former case; the organizable deposit is not favourably placed for further development, and a *false* corpus luteum is the consequence.—*Monthly Journal of Medical Science*, Oct., 1851.

PRACTICAL MEDICINE AND PATHOLOGY.

Laryngitis; Treatment by Topical Application.—By Dr. Hughes Bennett.

Dr. Bennett records two cases of laryngitis treated on Dr. Horace Green's plan, by passing a sponge charged with a strong solution of nitrate of silver upon and through the rima glottidis. Dr. Horace Green himself, happening to be in Edinburgh, operated in both instances. The instruments used are a tongue depressor, and a small piece of sponge strongly *sewn* on to a piece of whalebone. To introduce this the patient must be seated on a chair in a good light, the operator standing on the right side, and depressing the tongue with the left hand. Holding the probang in the right hand, it is to be passed over the upper surface of the depressor, exactly in the median line, till it is directly over the glottis. The patient is then told to inspire, and as he does so the tongue is dragged forward

by the depressor, and the probang is dipped downwards. Its passage through the inner glottidis is indicated by a sense of obstruction, which is felt to be overcome.—*Edinburgh Monthly Journal*, Nov.

[Nothing seems more easy of performance than this operation, as we read of it, but it is very different in reality, and not unaccompanied by danger and inconvenience. We have heard of one case of positive suffocation, and in all cases a transient suffocation is induced, sufficiently alarming to witness. There is no doubt, however, that where it is well borne, the effects of the operation are most satisfactory.—Ed. P. J.]

The Influence of Fear on a Quasi Paralytic.—By Dr. Atkinson.

[We report the following case, because it shows what power strong emotion has in removing the results of disease, and gives us a clue to the marvels of Prince Hohenloe and the not lesser wonders of modern mesmerism or electro-biology, which ever may be the correct designation.]

Dr. Atkinson tells the story of an acquaintance between forty and forty-five years of age, long subject to rheumatic affections of the joints of the inferior extremities, and who had become not a little stiffened or unpliant by repeated invasions of that complaint, who had determined on going to see a sick relative about ten miles from London. He got into the railway carriage after many irregular locomotive movements and some difficulty. Dr. A. seated himself by his side as he was proceeding on the same route. It happened, unfortunately, that he got into the wrong carriage, as it afterwards proved, for on division of the train into two parts at a particular junction, or rather a *point*, as it is understood in railway language, the bell rang for a change and a fresh start to two different directions. The whistle sounded: the invalid then for the first time discovered his error—he was clearly in the wrong box. The effect of *fear* of being carried away from his destination was instantaneous, or rather electrical; for simultaneous with the expression of "Good God!" he jumped out of the carriage with as much agility or nimbleness as if he had never undergone stiffening, and proceeded on his journey, wondering at the miraculous effect of a little fright. Dr. A. reports further, that he has continued much less inflexible than before the sudden convulsion of system.—*Lancet*, Nov. 1851.

SURGERY.

On the Treatment of Aneurism.—By Professor Syme.

Professor Syme appears to be a most uncompromising enemy to the treatment of aneurism by compression, and has repeatedly recorded cases with the object of illustrating the superiority of the ligature. His chief objection appears to be based on the length of time occupied by the former operation, which takes up time amply sufficient for crossing the Atlantic, visiting the wonders of the western world, and returning with the prolonged agony of compression, submitted to only through the authority of military discipline and tolerated only through the frequent administration of opiates, &c. &c.

In contrast to this vivid picture of the discomfort of the "clamps," he gives a case treated by ligature, in which the ligature came away at the end of a fortnight. —*Edinburgh Monthly Journal*, Nov., 1851.

Reduction of the Dislocated Femur without Pulley's or other Mechanical Contrivances.—By Dr. Reid, (U.S.)

The patient was a robust woman, and was bled and nauseated as a preliminary process. She was then placed on a lounge, on which a wide board was laid, and covered with a folded quilt. This made a firm table, about fourteen inches high, and about twenty inches wide, which gave Dr. Reid the opportunity of throwing the whole weight of his body on the flexed limb, while it gave him perfect command and control over it in every way. The patient was placed on her back, and a sheet, folded lengthwise, thrown across the upper edges of the pelvis bones, and each end given to an assistant, for the purpose of fixing the pelvis. Placing himself on the right and injured side, Dr. Reid seized the knee with his left hand, and the ankle with his right; he then flexed the leg upon the thigh, at the same time slowly carried the knee and dislocated femur over the sound one, pressing it firmly down upon it, and upward over the pelvis, constantly pressing it close to the body, moving it upward with a circular sweep over the abdomen, till the thigh was in a line with the right side of the body and the knee, pointing towards the right axilla. While the thigh was being carried up to this position, the bone or axis of the femur was performing a kind of rotation on itself, whereby the toe was coming more outward and the heel more inward. In other words, as the knee went upwards, the obturator externus, quadratus, &c., drew the head of the bone downward and inward towards its socket. When the knee and thigh were in the position above indicated, the heel was strongly rotated inward, the knee drawn outward, and the foot carried across the thigh of the sound side, when the head slipped into its place, and the limb glided gently down into its natural position. In doing all this comparatively very little force was employed, and very little pain produced, for the obvious reason that, by this evolution, the muscles that were in a state of extreme tension and irritation by the displaced bone, were gradually relieved and relaxed, as the head of the bone descended and approximated its proper place, which it did by the action of these same extended muscles.

It will be perceived, that by this mode of operating, we make a *lever* of the shaft or bone of the femur, and fulcrum of the edge of the pelvis, and by this means lift or dislodge the head of the bone, while the abductor muscles draw it downward and inward, making it as it were, *back* into its place, through the rent of the capsular ligament. Whereas, if it were drawn by direct force, as by the pulley, the head and neck of the bone would act as a kind of hook, and would tear away the capsular ligament, if it were only slit, and in some cases also, tear off the tendon of the pyriformis, for the abductor muscles are so strained, and hold the head of the bones so firmly to the dorsum, behind the ridge of he acetabulum, that it is next to impossible for it to mount over this ridge and into the socket, and must therefore descend behind it, tearing everything before

it—ligaments, muscles and all—and hence the immense power required to reduce it by these means; and hence, too, the failures, the fractures of the neck, and the cripples that have been made for life, by this barbarous and unscientific mode of reduction.—*New York Journ. of Medicine*, September, 1851.

HOMŒOPATHY AT TOTNESS: INQUEST.

A copy of the Evidence given at an Inquest held at the Exeter Inn, in Bridgetown, within the Borough of Totness, on the 12th day of November inst., and adjourned until the 14th, before W. Cockey, Esq., Deputy Coroner for this Division of Devon, to inquire into the cause of death of Alexander Charles Screach, aged four years and a half.

Rev. James Shore: (Not sworn.) Says he calls for an inquiry in consequence of his being accused of the murder of the child, or that he had killed it by his treatment, which he will shew by his witnesses, and that he will prove himself both justified and qualified to treat any sick person, and to prescribe medicines, having studied medicine for thirty years. That the medicines had cost him formerly fifty pounds, but now he permitted certain ladies to receive money as a remuneration; that those persons prepared the medicines in the breakfast room in his house, from his prescriptions, and delivered the medicines to his patients at his house.

Mr. William Bowden: (Sworn.) I am a surgeon residing at Totness; I examined the body of Alexander Charles Screach on the 12th day of November inst.; there were no marks of violence externally, no emaciation of the body; skin tinged yellow generally over the body, giving an idea that the child had jaundice. I then opened the head. On removing the cap of the skull, I found the membranes of the brain congested, the exterior membrane or dura mater was tinged slightly yellow; on removing the brain I found it quite healthy. I then opened the chest, the lungs were perfectly healthy, there were no adhesions or appearance of any former disease; the heart was also healthy; the abdominal organs were generally healthy; the stomach contained no food, and only a small quantity of mucus; the vessels of the small curvature were slightly congested, as well as those of the duodenum; the liver was healthy; the gall bladder was empty, with the exception of a little mucus; the kidneys were healthy; bladder full of rather high-coloured urine. I believe the child to have died from congestion of the vessels of the membranes of the brain.

Mr. W. Kellock: (Sworn.) I am a surgeon residing at Totness, I attended the examination of the body of Alexander Charles Screach with Mr. Bowden, and agree with him as to the cause of the child's death.

Mr. Shore: (Asked.) If jaundice might not produce congestion of the vessels of the brain?

Mr. Kellock: Certainly.

Mr. Shore: Might not violent sickness produce the same effect?

Mr. Kellock: Yes, but not permanently; the congestion might be the cause of sickness.

Mr. Shore: You said some of the vessels of the stomach and duodenum were congested; might not that effect be produced by ginger administered internally?

Mr. Kellock: That would depend upon the quantity given; I cannot answer that question unless you state the quantity, which I should think must be large to produce such an effect.

William Screach: (Sworn.) I am a tailor residing in Bridgetown, I am the father of the child, it had been ill since last Monday fortnight, I considered it looked yellow, and had the jaundice. Mrs. Turpin, a neighbour, told me that Mrs. Monteith had a child cured of jaundice by Mr. Shore, or from a prescription of his. My wife took the child to Mr. Shore's house, he prescribed for it, and I sent my son for the medicine to Mr. Shore's house twice; the first time there were twelve or fourteen powders sent, I cannot say which, and the second time twelve or fourteen powders, about twenty-six altogether; the powders were directed to be given every four or six hours, he did not know which; they were given to the child; the medicine produced no apparent effect; there was no alteration in the child up to Wednesday in the last week, it was running about and occasionally lying about very heavy. On Thursday my wife heard that Mr. Thompson had ordered some medicine for a child of Mr. Butland, chemist, of Totness, for the same disorder, and had soon cured it. She went to Mr. Butland and asked for the same medicine, and received four powders. [The prescription in Butland's hand writing was put in, it was powdered rhubarb, 5 grains, carbonate of magnesia, 5 grains, and ginger, 1 grain.] One powder was given on Thursday evening, one on Friday morning, and one on Friday night, 9 o'clock; in the course of half an hour the child vomited very much, and continued in that state for a long time, it was restless for many hours; it then became quiet; on Saturday night it appeared to be much worse, when I sent for Mr. Derry. He came directly and sent it four powders, but he did not say the child was so dangerously ill. I saw it take one of Mr. Derry's powders; it took no effect; the child was quiet until 5 o'clock on Sunday morning, it then became convulsed, and remained so until 7 o'clock in the morning, and died at 9 o'clock, about five minutes before Mr. Derry came to my house.

Elizabeth Seycombe: (Sworn.) Called by Mr. Shore and examined by him. Did not say Mr. Gillard had said that Mr. Shore had killed the child. I went to his surgery at Mr. Thompson's for medicine. Mr. Gillard was there and the dispenser; Mr. Gillard said, "so they say Mr. Shore has killed the child (I thought he meant Screach's child); what does he know about medicine." No name was mentioned.

Gervas Holmes: (Sworn.) Went with Mr. Shore to Elizabeth Seycombe, fearing she might prevaricate, to hear what she said about this case; she stated having had a conversation with Mr. Gillard, and that Mr. Gillard had made use of these words:—"Mr. Shore has

killed the child; what does he know about medicine." She then varied by saying that Mr. Gillard said:—"They say Mr. Shore has killed the child; what does he know about medicine."

The Coroner then remarked that they must be all satisfied as to the death of the child, and if other parties were aggrieved at Mr. Shore's practising medicine they must apply to another court; and Mr. Shore, if he considered himself charged with the death of the child, must apply elsewhere.

The Jury then retired for a short time, and returned their verdict that the child had died from congestion of the membranes of the brain, and that there was not the slightest blame to Mr. Shore.

Correspondence.

TREATMENT OF THE INSANE.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I have had forwarded to me two extracts from your journal, of letters from a gentleman who signs himself E.B., apparently the proprietor of a private lunatic asylum, the first of which is dated the 4th of September, and the other two appear to have been published about the 20th of September, on which I shall be obliged if you will permit me to make the following observations:—

In his last letter, E. B. states that he has read a paper "calling itself the alleged Lunatic's Friend Society," (*sic*,) and adds, "a more impertinent paper calling itself 'a report,' I never read." He then proceeds to allude to my name, I having signed the report in my capacity as Honorary Secretary of the Society, and according to the strict rules of justice adhered to by persons of his calling, alleges my wild enthusiasm and want of common sense as a ground for not wondering at that of the report,—that is, writes me down a madman or a fool, probably upon hearsay evidence. He then proceeds to give his description of that report, of which I will take the liberty of furnishing you with a copy, that you may judge for yourself of its merits, and I am sorry to say, falsifies the weight of it, when he declares that it only shows that "irregularities have been proved," &c. &c., but the characters of the proprietors remained unimpeached." In two cases, on the contrary, the characters of the proprietors are severely impeached, and I have no hesitation in saying that if justice had been done, they ought to have been very heavily find or deprived of their licenses altogether. E. B. further supposes that he makes a serious attack upon the report of the Committee of the Alleged Lunatic's Friend Society, by stating that it can find nothing to detail but what has been already before the public and adjudicated. Forgetting that in reporting cases which had been adjudicated upon, we were treading on sure ground, and calling the attention of the members of the Society and of the public to facts that could not be denied, and giving a detail of the result of our labours, whereas he appears to have looked, perhaps, from the habitual practice of his mind, for some *ex-parte* information, which we are very cautious about relying upon, and for a report of what we were doing and had left undone, instead of that which we had accomplished, which indeed would have been a very strange kind of report, and somewhat like certifying myself as a proper inmate for a lunatic asylum.

Leaving, however, E.B.'s strictures upon the report, which I have no doubt from his position, he feels a little sore about, I desire to remind him, that the objects of the Alleged Lunatic's Friend Society are two-fold,—1st, to procure an amendment of the Law of Lunacy affecting private patients; 2nd, to prevent the confinement and detention of persons upon allegations of insanity which are originally false, or which may have ceased to be true. Now, with regard to the first point, E.B., though regarding the law from a different point of view from ourselves, is a strong witness in our favour; for he says the act is difficult of comprehension, and in regard to certificates from the county, *impossible* to be immedidtely *obeyed*. With regard to comprehension, I would observe that none are so dull as those who do not wish to understand, and that the dulness that does not comprehend the law, whether real or artificial, does not go far to qualify the pleader of it for the care of an establishment of insane people. But it is evident that a law that cannot possibly be obeyed requires reform, and in this E.B. therefore coincides in opinion with the Society, only he desires it to be amended for his interests, to facilitate the admission of patients into asylums, we for the interests of mankind—that the safeguard against unjust confinement provided by the Legislature should be real and not *impracticable*.

We agree with E. B. also in another point, although again looking at the law in different views, when he complains of the power of the Commissioners being inquisitorial, their court a star chamber, and the Act giving no appeal. E. B. is very sensitive for his own rights and for the interests of those of his class. We do not blame him, but he blames us apparently for complaining of the same nature of proceeding in regard to the unfortunate persons confined in asylums, whose complaints, when they have the opportunity of making them, and the good fortune to secure attention, are investigated behind their backs, without the presence of any friend or attorney to represent them, and in a court bound by oath to secrecy, from which they have no appeal. Surely their position is still more touching than that of the lunatic doctor, in health and in the possession of wealth, and of liberty, and able at any rate to appeal to public opinion. This is one part of the law which we desire to be reformed, as well as E. B., and we have no objection to have his reasonable complaints attended to which he and his comrades have full power and liberty to sue for, but for God's sake do not let the complaints which we make for others, and which are, of injustice, of a still more cruel description, be treated as the result of want of common sense, or of wild enthusiasm.

E. B. has asked a question in his first letter, and I will ask another. Is there such a vice as injustice? Should not the Legislature pass a law declaring that there is no such vice, and that confinement or restriction of liberty, under the presumption of being guilty of any

imputation, is no violation of the rights of the subject? If the word or suspicion of a medical man, of the proprietors of an asylum for the insane, of his keepers, and of the relations of a party, are not taken as to the guilt of a common thief charged with taking a bushel of apples or potatoes from their gardens, and the accused cannot be committed to prison without investigation before a magistrate, minute, and on oath, or without trial before a jury of his countrymen, what renders the word and opinion of these parties so immaculate, that it should be sufficient at once to consign a person of some wealth or standing, male or female, to indefinite confinement, and loss of property and reputation, without any appeal to any tribunal? Such a diabolical system does not exist in France or America, or even in our channel islands, at least it does not exist recognized by the law, and it is a disgrace to our Legislature at our age. To remedy this system, and to give every patient, in person or through his friends, a fair investigation in his case, and appeal to some proper tribunal for a re-hearing of it, when there is reason to suppose that he is convalescent, is the sound object of the Alleged Lunatics' Friend Society, not in order to throw difficulties in the way of persons who are really insane and dangerous, or who need protection, being restrained, but to make the unjust confinement of sane persons, or of weak, nervous, but harmless and innocent people, next to impossible.

E. B. cannot object to me, as others do, that my apprehensions and those of my friends on this subject are fantastic, exaggerated, and so forth, for he acknowledges in his second letter—"at present it is perfectly impossible for any Commissioner's opinion to be of any value," and consequently the protection intended to be afforded by them to parties unjustly detained, is of no effect. Now, with all my wildness, Mr. Editor, I have never ventured to make, I believe, so sweeping an assertion; I am glad, however, to find myself out-hectored at last, as I have been in other instances, and on other occasions. *Now*, by E.B., and I am far from venturing to deny his authority, though I have hitherto contented myself by stating that from the hurried nature of the Commissioners' and Justices' visits, it was impossible that their opinion could be *relied* upon. It is true that E.B. uses this argument in a contrary sense to that in which I use it, but the testimony of opposing parties to the same fact is the best proof of its truth, and therefore I thank E.B. for wielding his sword in this cause even against myself and my friends, though he did not know when he did so that it was a two-edged one.

That which renders the existence of private lunatic establishments incompatible with the principles of sound legislation, is the temptation afforded to human weakness—to receive without much scruple, or to detain when no longer necessary to do so, persons, as patients, whose residence is profitable to the proprietor, or who may damage his interests by making an unfavourable report of his establishment; and the temptation to stint the patients in medicine, food, accommodation, exercise, amusement, or attendance, to make a greater profit out of the allowance for their maintainence. I do not know if these objections to such institutions can be effectually removed, because so much duplicity and plausibility is exercised in these matters. But as the first can only be taken away by giving the most perfect security and facility of appeal to the law to any party who conceives himself aggrieved, and guarding most effectually against any uncalled-for aggression upon the personal liberty of the subject, on the pretence of insanity, and by treating the suppression of the appeals of an alleged patient to his relations, to his friends, and to the authorities, as a henious offence. I trust that E. B. will see that the interests of his patients and his own are the same, and that the objects we pursue are so far conducive to his own interests also; as unless they can be obtained there can be no question that private asylums for the insane are a nuisance that must be abolished, and an expensive nuisance, costing so much for their present—even as acknowledged by himself—ineffectual surveillance.

I have the honor to be, Sir,
Your obedient humble servant,
JOHN PERCEVAL.

Parthenon Club, Regent Street,
Nov. 1, 1851.

Medical Intelligence.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted Members on the 7th instant:—Robert Bowman, Richmond, New South Wales; William Taylor Colby, New Malton, Yorkshire; Henry Samuel Colston, Bombay; Walter William Harris, Australia; William Haughton, Dublin; John William Howard, Fenchurch Street; John Black Paterson, London; William Robinson, Carlisle, Cumberland; John Wills, Shaftesbury, Dorset.

The following gentlemen were admitted members on the 14th inst.:—Charles Chibnall, Tothill Street, Westminster; James Collier, Aberdeen; Wm. Edward Day, Bristol; Joseph William Eastwood, Chesterfield, Derbyshire; Edward Ross Prance, East Stonehouse, Devon; James Martin Roche, Fermoy, County Cork; James Edward Turford, Boston, Lincolnshire.

SOCIETY OF APOTHECARIES.

The following gentlemen were admitted on the 6th inst.:—William Adams, St. Austell; James Cornish Crossing, Devonport.

Gentlemen admitted on Thursday, the 13th inst.:—James Joseph Cregeen, Ramsey, Isle of Man; Robert Wilkinson, Bradford, Yorkshire.

APPOINTMENTS.

Dr. Parker has been elected Assistant-Physician to the London Hospital, in the room of Dr. Pereira, appointed Physician.

OBITUARY.

On the 15th inst., at Craddock House, Uffculme, Devon, John New, M.D., in the 83rd year of his age.

TO CORRESPONDENTS.

Communications have been received from Mr. Harvey (twice), Dr. Tunstall, Mr. Bree, and the Birmingham Pathological Society.

LECTURE

ON THE

DISEASES OF CHILDREN.

DELIVERED IN THE

Chatham Street School of Medicine, Manchester,

By Dr. MEREI,

Fellow of the Hungarian Academy, late Professor of the History of Medicine at the University of Pesth, Clinical Professor of the Diseases of Children, and Director of the Children's Hospital at Pesth; Fellow of the Imperial Society of Medicine at Vienna, etc.

Lecture VII.

Examination; Diagnosis; the First Steps of the Practitioner; Milk, Food, Diet.

Gentlemen,—The examination of an infant, or a little child, that cannot answer our questions, is a difficult task, which requires particular qualities on the part of the physician; without the qualities of an exact observer, and without a good deal of delicacy, patience, and cleverness in the whole proceeding, the results will be quite uncertain. I will not speak here about the natural dispositions, nor am I able to point out all the particular means, and variations of these means, suitable to the various cases, by which, in some instances quickly, in others only after a long and repeated series of observations and inquiries, we unveil the malady. I recommend, however, and will bring before you, a certain method and order in this business to which a young practitioner must in general attach himself, in order to obtain by practice a satisfactory degree of skill.

All your senses must co-operate in this task; but, above all, your eyes should be accustomed to read the countenance of the child, and to survey so closely the whole frame, that not a single muscular movement in any part of the body may pass unnoticed. Be not deterred by the difficulties. I have no doubt you will more than once look into this book of nature before it becomes legible to you: you will fix your eyes upon, and watch the countenance of the little patient, and find no clear expression in it, and this, perhaps, in a great number of your first cases. But continue, nevertheless, to employ the same method with intense application; the time will come when you will perceive impressions and understand signs, which formerly have been hidden before your eyes, and which, to superficial observers, continue to be so.

At your *first visit*, in particular, if you are a stranger to the child, and this latter older than five or six months, you must be careful not to frighten the little patient, either by the sound of your voice or the fixity and expression of your eyes and countenance; you must avoid even to attract its attention, because a sick child once alarmed, irritable and crying, becomes a subject the more obscure as it is intractable.

If I find the child either in its bed or in the arms of its mother, in both cases when I enter the room I take position at a certain distance, which allows me, however to observe it by an occasional glance. Then, supposing the child to be in its bed asleep, I observe it for a certain length of time as closely as possible, with particular regard to the respiration, occasional sighs, moans, and movements of the head, the body, or the limbs; and there are cases in which it is possible to accomplish our task for that visit without consenting to awake the child. In general, however, it will be necessary, after a time, to awake it, to put it into various positions, to observe its respiration and general behaviour, in the dorsal as well as in both lateral positions; then we request the mother to take it up into her arms.

If I find the child in the arms of the mother, in certain cases (in particular, of suspected or evident affections of the organs of the chest,) it will be desirable to observe it also for a while in the mentioned various positions in its bed; but after this, and almost always, I accomplish the most important parts of the examination whilst the child is in the arms; this being in general the more favourable position for our eyes, ear, and hand, and the less likely to provoke the child's reluctance.

Directing, then, the person attending on the child to walk with it to and fro in the room, I follow it with my eyes, observing its countenance, the keeping of its head, and every movement or expression.

When the position of the child gets changed, and the body or single members moved, an occasional moaning, or cry, or other expression of pain, must not escape our attention, as it may lead us to discover some affected locality.

During all this time we ask for information with regard to all points of the management and habitual behaving of the child, the progress of its development, and the circumstances connected with the present malady.

It is most important to get a just idea of the complexion and disposition of the child. Accordingly, we cause the belly and the legs to be for a moment uncovered; after which, if the case seems to require it, we do the same with the chest and arms. If the patient is above six months old, we ask about the progress of the dentition, the ossification of the fontanelles, and the muscular power of the legs and arms.

Then we approach (in cases of irritable children, the best from behind and unnoticed) touch the region of the fontanelle, in order to ascertain the state of the ossification, and touch then for a short time, and in a delicate way, the pulse. Then we advance cautiously our right hand from behind under the clothes over the belly, and exert gradual pressure in different regions of it; at last, if we suspect a disorder of the respiratory organs, we press in a direction and degree to push the viscera upwards towards the diaphragm, by which act the inspiration becomes difficult and forcible, so that we may perceive a significative change in the breathing of the child.

All this manipulation must be performed, in general, quickly and in an easy manner, with more or less

caution and subtilty, according to the various temper of the child, in which, if it is very irritable, it is desirable that one or more persons assist us, by distracting its attention, whilst we touch its body in a more or less concealed way. The success of our diagnostic operations depends very much upon its crying being avoided before and whilst we examine the abdomen.

Then we proceed to the chest, by auscultation and percussion; and, as I mentioned in the third lecture some particulars concerning these most valuable means with children, I will here only advise you to commence in general with auscultation over the dorsal and postero-lateral regions of the chest. In or near these regions is the usual seat of the greater part of the affections of the lungs and pleura; and it will be easy to give to the child a position on the arm of the mother or nurse by which we are enabled to auscultate upon these regions from behind, and perhaps unnoticed by the child. Then, if we deem it necessary, we auscultate on the anterior part, and as this most frequently causes crying, I recommend you to auscultate at first over the heart, inasmuch as loud crying, and the arterial excitement caused by it, conceal or pervert some movements of this organ, whilst the sounds and râles of the bronchi are not so easily veiled by it. If I see or suspect the child to be very irritable, I use always on the anterior part the stethoscope, but posteriorly the immediate auscultation.

Finally, as percussion almost invariably causes crying, we must practise it the last, and in all those cases, at first upon the abdomen, in which we deem an exact investigation of this cavity necessary, which by crying becomes the most difficult. The percussion of the chest, the most enlightening in children, can be successfully practised even amidst violent crying.

We must, then, pay all our attention to the condition of the skin and of the joints, including their mobility. Nothing is more usual than a superficiality in this latter respect, by whichI have seen severe rheumatic affections, and even a degree of swelling overlooked by the physician in repeated visits.

If the little patient cries from time to time very violently, with all the expression of severe pain, of which we know not yet the seat, in this case we must carefully investigate the state of the ears, the gastro-intestinal, and the urinary functions; because pains and spasms in these parts are the most severe, and much more common with infants than with adult patients. We shall be able in general to detect the seat of pains and spasms, partly by a certain series of questions, partly by the directions which we give to our own observation, and to that of the attendants.

It would be too long to enter here into a detail concerning the abdominal, including the urinary symptoms. Some particulars upon these, as well as the other parts and functions, I tried to expose to you in the former lectures, from their objective point of view; in the present, I wish only to offer a kind of *general scheme* of the examination of a little patient,—a scheme and an *order* which every intelligent young physician will be able to modify according to each single case.

I beg, however, to recommend warmly to your attention, the order and the reasons of that order in the procedure of the examinations, which occasionally you may modify, shorten, or prolong, and strengthen by the microscopic and chemical tests, with the utmost minuteness, according to the nature of the case, whilst I can assure you that irregularity, superficiality, and want of cleverness, have still their share in the examination of little children, and engender many faults in their treatment. In spite of all exactness and cleverness in examination, however, a practitioner, well aware of the difficulties and obscurities in this department of medicine, will frequently postpone until his next visit the accomplishment of the diagnosis and of a decisive line of treatment. The parents in general ask with eagerness our opinion upon the case, and expect anxiously the prognosis; but the rapidity of changes with children's ailments, makes it necessary on the side of the physician, to speak and act with careful reflection and reserve, in order to avoid future disappointment and contradiction.

If the case be not the most evident, our first prescription, if at all necessary, must not be too active nor too special; but, if possible, of that kind which may contribute to enlighten the case for to-morrow. Thus, suppose we cannot make it clear, whether the pain of which we see the unequivocal manifestations, has its seat in the abdomen, in the brain or the ear, a mild purgative or soothing injection, and linseed poultices on the belly, will frequently enable us at our next call, to settle the diagnosis by its effects, positive or negative.

Milk, Food, and Diet.—It will be almost invariably necessary, to give at the first call our opinion and directions concerning the nourishment of the child. I will bring before you in a few words the principal points of my experience on that subject.

A healthy mother ought to suckle her infant, this is the most favourable for both parties; but a mother of an unhealthy complexion, or very delicate, subject to nervousness, or being of an hysterical irritable temper, or one who feels very much weakened, with pains in the chest during the act of suckling, ought to be strongly requested to abstain from, to shorten, or end the lactation. It is, however, not always an easy task for the physician to decide in this matter of lively feeling. It is not rare to find, with very delicate females, plenty of milk, and their infant prospering by it, whilst they become weaker and thinner themselves every day. This we may concede for a certain time, but oppose earnestly, as soon as pains in the chest, or disturbance in the functions appear. In a nurse I would also very much look on the state of the skin and teeth. Excepting certain acute and decidedly local affections of the skin, of a short duration, all others, even light but *chronic* eruptions, seem to me objectionable in a nurse; the pustular more than the vesicular, and porrigo more than impetigo. Ladies of a fatty complexion, who are *embonpoint* and have large fatty breasts, frequently secrete too little milk, or of a thin innutritious quality. We see this by pouring a few drops into a

glass full of water, when thin milk will not form those bluish-white pearl-coloured molecules, proper to a more nutritious quality, but soon dissolve and mix with the water. By the microscope the milk in the first weeks after delivery presents a small number of regular spheroid milk-globules, and a large amount of irregular little bodies (Dr. Donné's "corps granuleux") and another kind of viscid or mucous matter floating in the serum, but after that first period a good milk must show a large amount of regular milk-globules. Casein, the essentially nutritious element, is by the soda of the milk kept in a dissolved state; consequently it is less perceptible by physical means.

A thick and heavy quality of milk is not always proportionally nutritious; it may contain a large amount of fat globules, and other lower elements, and less of the most important casein, it will not consequently be recommendable. It may be also too heavy for the infant's digestive powers. It appears already from this, that in case we should have to recommend a nurse, we must not recommend one whose milk is much older than the infant. There are, however, some qualities, both positive and negative, in the milk, which we cannot yet discover, though experience convinces us of their existence; these are certain *vital* qualities, in one case beneficial, in another mischievous, to the digestion and vegetation of the nursling, and we must frequently in cases of lactation form and pronounce our judgment according to the observation of the effects upon the child. Thus the existence of the catamenia of suckling mothers and nurses is, in the majority of cases, a circumstance announcing a damaged milk, and the necessity of abstaining from lactation. This is often imperious with females who, during the catamenial periods, suffer very much from headache, abdominal spasms, and loss of appetite. This is, however, not the case with some plethoric women, whose catamenia do neither disturb their health, weaken them the least, nor disturb or pervert the effects of the lactation upon the child.

If the suckling mother or nurse is of a suitable complexion, it will be the best plan to limit the nursling's nurture only to the milk till about the fourth month, or even above; then the next addition to the milk of the breast may be, at first once, and further, twice in the day, a decoction of cocoa, with the addition of a little milk and sugar, or a light chicken or mutton broth, (not fat); towards the seventh month with a little biscuit or sago boiled in it. There are some other kinds of food also admissible for that age; for the one child the one will do better, and for the other another. And the complexion or state of health of the child requires also, in many cases, modifications of the general rules. Common sense and observation is the best teacher also in that particular. I beg, however, to recommend to you the following points, as leading principles in the great pleurality of cases. Milk, or other likely liquid food, should not be given oftener to a young infant than at intervals of three hours; this secures a better digestion. The age naturally fit for weaning is that of from nine to twelve months; in some cases of delicate children we prolong the period of suckling something more.

If circumstances necessitate the feeding a newly-born infant without the breast, or to wean it long before the natural period (the eruption of the teeth), the best, at least the safest, substitute in the first month will be two parts of *boiled* fresh cow's milk mixed with one part of a very light infusion of aniseed, so as to impart only a slight aromatic property to the milk, and give a little sugar with it. The addition of the aromatic water can then be, in the second month, gradually diminished, and at last entirely left off.

Before the ninth month it is scarcely ever necessary to give more substantial food than that I mentioned before, beef-tea or broth, with sago, biscuit, and semola.

After the age of from the twelfth to the fifteenth months it is almost invariably advisable to accustom the child gradually to a more substantial food; for instance, besides sago, barley, or rice, boiled with broth, a little of mild vegetables, as a second dish, and to advance about the eighteenth month to a little tender meat. These points, however, are subject to modifications by the complexions or particular dispositions of the children.

If the child has a large abdomen and skull, and its hair resembles flax, if there is great voracity of bread or other farinaceous food, in this case we must try in a proper way to accustom the child more and more to animal food, and to restrict all that is farinaceous. I have described the disposition in question in the sixth lecture, under the name of "scrofulo-impetiginous" habitus.

For the mentioned complexion (not unfrequent) a common fault and mischief is committed by feeding them already in their tender age with a composition of milk with bread, or other farinacious articles, which combination is the worst of all for them, being generally very liable to produce acidity and flatulence, not seldom an unhealthy chylus, and bad assimilation.

Those complexions which I have described (lectur sixth) as nervous and sanguine do not want much of animal nourishment, not even in the second year of age; and the children with dark-coloured hair and brownish skin, with a dark red hue on the cheeks (bilious and plethoric) require in particular and essentially the use of preserved fruits and boiled greens.

Sometimes we are obliged to change the kind and manner of nourishment; but, as rules of importance, I wish to establish the following:—Till about the fourth month only milk; till about the eighth month only one liquid kind of food, besides milk, once or twice every day, in regular hours and quantities; during the second year twice thin liquid and twice more substantial; during the third and fourth year twice liquid with some bread, and twice a more solid food; only one of these meals, however, ought to consist of two qualities of dishes, one of which may be meat, as the principal repast of the day.

If we observe regularity of time and simplicity of kind—that is, if we give to the child continually, at the same periods of the day, the same kind of food, two

advantages are obtained:—the stomach and other abdominal organs will at that time and of that kind digest better, and it will be more easy under this regimen to detect the first commencement of functional derangement and malady. Frequent variations with the kind of food lead to voracity and indigestion.

I forgot to mention the occurrence of pregnancy as an imperative reason for weaning the infant. Sore nipple, if severe, unmanageable, and causing to the mother, during the act of suckling, insupportable pains, may also be regarded as a circumstance making weaning necessary.

With regard to *diet and hygiènic means* I think I need not enter into particulars. The important specialities of *therapeutical diet and hygièna* I suppose to be in general known to you; and some indications and modifications of the kind result also from what I have brought before you when speaking of the different kinds of food convenient to the different dispositions and ages of children. A good ventilation of the room, a convenient sort of clothing, a suitable kind of bed, and attention to be paid even to the position of the child, different in different maladies; these are points easily to be understood. Let me, finally, remark that in inflammatory diseases a reduction in suckling, viz., in the quantity of the milk of the breast, and, at the same time, the frequent use of cold water; in acid and flatulent dyspepsy, again, complete abstinence from farinaceous food. These measures act sometimes more powerfully in children's ailments than pharmaceutic substances. Next I shall speak upon the most useful remedies in children's practice.

ON THE IMPORTANCE OF DISCRIMINATING BETWEEN

PREGNANCY & ABDOMINAL DISEASE.

ILLUSTRATED BY A VERY RECENT CASE.

By DAVID NELSON, M.D., Edin.,

Physician to the Queen's Hospital, and Clinical Professor at Birmingham.

There is no subject upon which it behoves the medical practitioner to exercise more care and caution than the above. Considering the magnitude of the physical and moral consequences involved in the question, and the well-known obscurity of many of the symptoms presented to us, along with the great difficulty of determining either their positive or their relative value, we ought to search diligently for every available proof on the one side and on the other, and yet, after all, ponder over the matter well and deeply before we commit ourselves to a decided opinion; for, if we only recal to mind the ordinary symptoms of pregnancy, we shall at once see that almost all of them are beset with doubts, and that their strength consists more in their number than in their individual weight. Thus, for instance, the increase of size in the abdomen may be due to sundry other causes, as polypus, ossification, hydrops uteri, and hydatids. So may the irregularity of the menses, which discharge, from being profuse in the earlier or irritative stages of ovarian or uterine disease, may be quite stopped in the later. Sickness is certainly no criterion of itself. The enlargement of the breasts and of their areolæ, and also the secretion of milk, may take place under other irritations of the ovary, as well as pregnancy. Kiestine in the urine has now been shown to be a very doubtful mark. Even the supposed movements of the child, when only felt through the parietes of the abdomen, may be simulated by rushes of gas under certain forms of disease; and, though the stethoscopic signs of the cardiac and placental sounds within the womb must always afford proof positive of the presence of a living child; they are, of course, not applicable to one that may be dead. Ballottement is certainly a very valuable sign, but when that and the stethoscopic evidences are wanting, it becomes us to look with much discredit on any of the other symptoms, the most of which are merely sympathetic. Moral considerations are also to be taken into account in such a review of any case, as the station, known principles, and habitual manners of the patient. That great difficulties will beset certain cases, even when there exists the most earnest desire to arrive at truth, there can be no doubt, as witnessed in the memorable instances of Queen Mary and of Lady Flora Hastings. But these difficulties should only afford a wholesome lesson against rash conclusions, especially when ladies are unmarried, of mature years, and of superior character; and the following case, as resembling in the most essential point that of the late Lady Flora, is now adduced, to enforce such caution, especially on the part of our younger brethren. The writer holds a very strong opinion in regard to the non-publication of cases occurring in private practice, but he conceives that that principle does not apply to occasions such as the present, when he can positively vindicate, and feels that he ought to vindicate, the injured reputation of a deceased female patient, who, though conscious of innocence, was yet deeply wounded by the widely-spread suspicion against her. The facts are as follows:—

Miss P—— of this town, and late of Henly-in-Arden, aged about 34, of pious reputation, and unmarried, had, about eight months ago, or more, first become conscious of an uneasy pain at the lower part of the abdomen, which was by and by followed by a swelling in that region. At first, without being subjected to any particular examination, she had been treated for dyspepsia, and some hepatic affection, by a general practitioner, to whom she did not seem to have mentioned the above notable fact of enlargement. Afterwards, as the disease advanced, and assumed a more serious aspect, others were called in, and a physician of some standing, and others of obstetric experience, at length thought it necessary to declare positively that she was pregnant, in order to save professional reputation. Accordingly she was treated under this idea for some time, until, from certain communications to that effect, the patient and her friends declined further

attendance, and decided on calling the writer in to pass an opinion. He visited her, accordingly, on the 12th of last September, requesting that Mr. Partrige, of the same neighbourhood (Bordesley), should meet him, as that gentleman had had some general management of the case before that period. On arrival, he heard from the mother and the patient what previous opinions had been given. Mr. Partrige also stated that pregnancy had been affirmed in the case, limiting, however, his own view to a statement of the plain physical facts alone, viz., that there was fluctuation, with a solid or fluid body in the neighbourhood of the uterus, and occasional movements.

On examination, the patient was observed to be of small stature, and much emaciated, with a calm and interesting expression of countenance. The head was cool, the tongue clean and rather red, stomach tender, bowels obstinate, and kidneys torpid. The pulmonary sounds were natural; heart's action small, smart, and rapid; pulse 100 to 112. The abdomen was enormously distended with fluid, having a most distinct fluctuation all round, except just over the pubes and under the liver. The parietes were so tense that it was difficult to press them down. Still, however, they could be sufficiently dimpled to permit of the discovery of a more solid and pretty large body, like a child's head, in the left iliac region, which twice or thrice seemed to move with a jerk against the hand; while, on the right side, under the liver, there was an extensive doughy mass, distinctly margined, and giving the idea of hepatic enlargement. The os uteri was high up, and the cervix was scarcely distinguishable; but neither the placental blowing, nor the cardiac tic-tac was to be heard. The breasts were not enlarged; there was no remarkable areola, nor any milk in the nipples. A scum did form on the urine, but that disappeared under acetic. acid. She had also menstruated some time before (explainable, perhaps, by the exhibition of certain medicines). The test by ballottement was not tried, as, besides the above negative evidences, she had that calm and straightforward look of the eye which seldom accompanies any such concealment as was supposed. The opinion then given was, that there was no evidence of pregnancy; but, certainly, every evidence of universal abdominal fluid, possibly ascites, with a solid body within it, most probably an ovarian tumour or cyst. Respect was certainly paid to former opinions on the subject, especially as they had been formed at an earlier period, before the abdominal fluid had so buried the tumour within, and thus beset the case with innumerable difficulties; but still the diagnosis was sufficiently confident to justify a decided plan of treatment. She had much flatulence, and was ordered pills of aloes and assafœtida, along with a course of iodide of potassium, and blisters; under which treatment a patient of the writer's, now in the Queen's Hospital, has obtained much relief, with a diminution of the tumefaction. On the 14th, however, it was discovered that her digestives were so irritable that they could not bear the iodide of potassium, which was, therefore, discontinued, and a preparatory treatment substituted, of compound tincture of gentian with hydrocyanic acid. On the 16th three leeches were applied over the liver, where there was pain, while she commenced some mercurial frictions over the abdomen; and, as the bowels and kidneys did not act, purgatives and diuretics were also resorted to. These, however, had no effect; and, as the legs began to swell to a great degree, while the fluids, &c., pressed upwards on the diaphragm, and fluctuated even over the pubes, the writer proposed that tapping should be resorted to. As, however, there was a married female friend present, who specifically put the question in regard to pregnancy once more, and recalled to mind the positive affirmations formerly made, it was considered proper, in full justice to the patient, that some eminent *surgical* opinion should be taken before that procedure was adopted. Accordingly, after a day or two, Professor W. Sands Cox, F.R.S., met Mr. Partrige and the writer in conference. He conjoined in the opinion that there was no evidence of pregnancy, but that there was a vast accumulation of fluid, and some very solid body within it. He deferred tapping, however, and only advised the feet to be punctured for the œdema, which operation was performed by Mr. Partridge, and gave, for the time, some relief. Shortly afterwards some erythema set in, and healing measures had to be resorted to forthwith. The distress now increasing, Mr. Cox was again summoned; and on the 19th of October, in the presence of the writer, and assisted by Mr. Partrige, he performed the operation of tapping, per vaginam, without inflicting the slightest pain, when there drained away about two gallons of thick fluid, like pea-soup, found to be almost pure albumen. After this had ceased to flow, the belly still remained very large, but was much softer. The tumour, also, in the left iliac region had disappeared, though the doughiness of the right side remained as before. It was not deemed prudent, for the present, to tap again through the parietes of the abdomen, and she was accordingly bandaged round, and left at rest, feeling considerable relief in her breathing, &c., while the œdema of the legs had almost at once diminished. She was so wasted and faint, however, from her long protracted sufferings, that this ease proved but a brief and partial respite. Her appetite and flesh were gone, and all her organs so torpid that, with the view of hastening her improvement, she exceeded the prescriptions given her, and swallowed of herself, one after another, many strongly purgative pills. These only increased the flatulency and gastro-enteric irritation, without producing the desired effect, and she gradually sunk and died on the 24th.

On the 25th, Mr. Cox being from home, an autopsy was instituted by the writer and Mr. Partrige, in the presence of the nurse and another female attendant. On cutting through the abdominal parietes in front, a large thick sac was found closely adherent to the walls, and from this sac was drained off upwards of three or nearly four gallons of an albuminous fluid, as before (for there were no means of exact measurement). There was then seen a large solid mass attached to the right wing of the uterus, and stretching away under

the liver. The uterus itself was pulled up by it. This mass appeared to be of the weight of about four pounds. On cutting into it, it had a fibrous covering, and appeared partly solid, and partly of honey-comb structure, from which exuded a bloody and brownish-white matter. This, under the microscope, was observed by Mr. Partrige and Dr. John Wright, Resident Officer at the Queen's Hospital, to consist partly of fibrous filaments, with pus, and blood corpuscles, granular matter, and fusiform cells. The sac was universally adherent, of a thick, leathery, fibrous structure, interspersed with large vessels, and here and there it presented extensive patches of inflammation and effused lymph on its inner surface. The liver was soft or almost diffluent in some parts, and of a dirty grey colour. The uterus was of natural size and structure, and on being cut open, there was *no pregnancy*.

Birmingham, Nov. 1, 1851.

SOME REMARKS

ON CONSTIPATION AS ATTENDANT ON CHRONIC UTERINE DISORDERS.

By JAMES TUNSTALL, M.D., Edin.,

PHYSICIAN TO THE EASTERN DISPENSARY OF BATH.

That an intimate sympathy exists between the reproductive organs of the female and those of digestion, is a fact so self-evident that I need not dilate upon it. Familiar instances occur in the vomiting of early pregnancy and the diarrhœa which more or less attends upon the catamenial secretion in those in whom this function is attended with pain and difficulty. In these latter cases costiveness, of an habitual character, is the general state of the bowels, and it is in them that the greatest amount of mischief is produced by the habitual use of the stronger aperients and mercurials. I do not think that contiguity of structure affords a sufficient explanation of their phenomena, but that they are to be regarded as examples of reflex nervous action.

If we proceed to consider the hysterical paroxysm in its completeness, we find the majority of the organs supplied by the great sympathetic, more or less participating. We have irregular or painful menstruation, excessive secretion of urine, costiveness, difficulty of breathing, with palpitation, giving rise to convulsions, partial paralysis, and other results of reflex actions. While the paroxysms are intermittent in their character, the functional derangements of the uterus and larger viscera remain, the reflex action still continues, in some cases manifesting itself in a short, dry, husky cough, in the majority constipation. These cases are characterized by an irregular action of the muscular fibres of the intestines, producing irregular and atonic propulsive power, just sufficient to enable the patients to pass small quantities of scybalæ only, with great pain, the great mass of fæces remaining; resort is then had to cathartics, an artificial diarrhœa is sought to be produced, and thus the bowels are excited into an undue action, to relapse again into an additional degree of torpor. Mr. Collett, in the *Journal* for November 12th, has, I think, clearly shown, that many of the ordinary cases of simple constipation may be relieved by the judicious plan pointed out by him, but in cases similar to those I am about to relate, I conceive we want something more, in other words we require to subdue the nervous irritability, both of the uterus and intestine; not merely to subdue the constipation, but to remove the exciting cause, to regard the two organs as acting and reacting upon each other, and to endeavour to restore the healthy function to both. I shall assume, for granted, that the constipation depends upon irregularity of muscular action, and not upon the capacity of the female abdomen and pelvis, and that its remote cause is uterine functional derangement. Thus, then, our treatment must be tonic and anodyne, rather than aperient, and the diet of the patient should be strictly regulated. Conium appears to me to exert a peculiar action in uterine cases; it does not constipate like opium, and is far more manageable than belladonna. In small doses it does not affect the head, which in the cases under notice is a great desideratum.

Shortly after Stork had introduced conium to the notice of the profession, as a valuable remedy in cancerous affections, the celebrated Dr. John Fothergill published some observations upon it in the third volume of the "Medical Observations and Inquiries," lamenting that it did not answer his expectations, he says it proved beneficial in various obstinate complaints. In the conclusion of his paper he makes the following remarks:—"The extract of hemlock is apparently anodyne; it promotes rest, and eases pain; it seldom occasions that kind of morning headache which succeeds an opiate. In most cases it produces a laxative stool the following day. In some habits it offends the stomach, producing spasmodic twitchings. I have been induced to try it in painful discharges from the vagina, and often with success; also in fixed excruciating pains, probably arising from acrimony."

Fothergill being engaged in testing its efficacy as a remedy for cancer, gave it in large doses. He prescribes the extract to the extent of two scruples during the day, and continued it until its physiological effects were produced. I have never exceeded five grains during that period.

In the cases now under consideration, its evident effects were first anodyne and soothing and then mildly aperient. It produces, as it were, an evacuation by its direct action upon the muscular fibre, by subduing irregular contractions, in addition to its sedative effect upon the uterus.

The following illustrative cases are selected from my diary:—

Case 1.—Mrs. K., aged 30, who had suffered 7 years from prolapsus uteri, caused by severe abortion, attended with great nervous irritability and habitual constipation, having been advised to come to Bath for the use of the waters, placed herself under my care in the early spring of 1850. When examined, I found the pulse feeble, 60;

the tongue large, clean, indented at the edges, and very pallid; breathing natural, no affection of head or chest, slight globus hystericus, stomach and bowels morbidly irritable with constant borborygmus, obstinate constipation with scybalæ, and great discharge of fibrin; secretion of urine irregular; prolapsus complete. She described her state as one of imperfect paralysis, being unable to walk without assistance. She stated that her bowels never acted without an aperient, the operation of which increased all her symptoms. I commenced the treatment with a thermal bath three times a week, under which her strength and appetite improved. After a fortnight, I prescribed Extr. Conii, gr. ij.; Pulv. Rhœi Turc., gr., j., in a pill to be taken every night, directing her to continue the bathing. After taking the pill regularly for a month, her state was thus recorded:—"Evidently better, the bowels act every alternate day; she is able to cross her room without assistance; the catamenia have occurred with less pain than usual; the prolapsus is not nearly so distressing." She continued the treatment for three months, when she returned home, enabled to attend to her household duties with comparative ease, and enjoying a fair share of health, in which state she still continues.

Case 2.—A lady, aged 46, unmarried, became my patient in September, 1850, suffering from severe dyspepsia and constipation, menstruation profuse at short and irregular intervals, with great prostration of strengh, and extreme nervous irritability. She informed me that the catamenia had always been attended with so much pain that she dreaded the return of the periods, that her life had been a constant burden, and that she had never been able to do without the constant use of cathartics. She had tried every remedy, dietetic as well as medicinal, without effect. She had, prior to consulting me, drank the Bath waters, but as they increased the discharge and caused headache, I directed them to be omitted.

Having satisfied myself that the menorrhagia was purely functional, I first applied myself to its relief, and having succeeded, I prescribed as follows:—R. Extr. Conii, gr. iij.; Pulv. Rhœi Turc., gr. j. M. Fiant pilulæ ij., omni nocte sumend.—R. Magn. Sulph., scr. iv.; Ferri Sulph., gr. iv.; Tr. Hyoscyam., dr. iij.; Aquæ Distillat., oz. vss. M. Capiat cyathum bis die.

This treatment I continued for six weeks, the bowels recovered their tone, the catamenia appeared at irregular intervals for a few hours only, and she returned home improved. Three months after her return she wrote to inform me that the menstrual function had entirely ceased, and that the bowels acted regularly and well.

Case 3.—S. H., aged 26, a domestic servant, applied to me at the Eastern Dispensary on June 19, 1850. She suffered from obstinate constipation, severe headache of an intermittent character, with hæmatemesis and menorrhagia. I directed her to take the disulphate of quina, in infusion of roses, which removed the headache, and she discontinued her attendance.

On the 24th of July she again presented herself, suffering from profuse menorrhagia and vomiting of blood, attended with obstinate constipation. I prescribed Ol. Terebynth. and Ol. Ricini, of each half an ounce, to be taken the following morning. This resulted in the expulsion of a tape-worm, with relief to the symptoms. I directed her to repeat the dose on the 27th, which brought away a large quantity of offensive fæces.

On the 1st of August I prescribed Argenti Oxyd., gr. ss.; Extr. Conii, gr. iij., in a pill, which I directed her to take twice a day; this she did for seven weeks, when she reported herself cured. I should not omit to mention that the sanious secretion from the stomach ceased with the exhibition of the first dose of turpentine, and that I have seen two other cases in which tape-worm and menorrhagia occurred in the same person.

Case 4.—Mrs. H., aged 32, one child aged 7, suffered severely from uterine hæmorrhage in her confinement, from which she has never properly recovered, consulted me on the 27th of May, 1851, complaining of the following symptoms:—"I have suffered," said she, "ever since my confinement, with headache, great irritability of nerves, with apprehensions of calamity. I am afraid to walk, for the slightest excitement produces palpitation, with a tendency to hysteria. I never have a proper evacuation from the bowels, I suffer from dyspepsia, and my fingers are half dead. In this case there was evidence of great prostration. The pulse, although natural in its beat, was deficient in calibre. Upon inquiry I found that the catamenia were irregular, both as to time, quantity, and appearance, and that all the symptoms were aggravated at the periods. The whole pharmacopœia had been sought in vain for anti-spasmodics and aperients. I interdicted the use of all medicines specially directed to the relief of symptoms, and directed her to take a nourishing rather than a stimulating diet. I ordered her a pill consisting of Extr. Conii, gr. ij.; Pulv. Rhœi Turc., gr. j., every night, requesting her to avoid all aperients, except castor oil. Early in June she went to the sea-side, and I did not again see her until the 22nd of October, when she reported that she had taken no aperient since leaving Bath; that when she required one, the pill was amply sufficient for the purpose; and that she was enjoying a state of health to which she had been for years a comparative stranger.

Practical Remarks.—I am perfectly aware that we are all disposed to look upon a favourite remedy wit approbation; I have, therefore, selected these four cases, because the means employed differed in each case. Taken as a group they illustrate the necessity of our endeavouring in all chronic cases to make ourselves thoroughly acquainted with the state of every organ likely to be implicated. That they act and react upon each other the case of S. H. proves. There can be no doubt that the presence of tape-worm was the cause both of the abnormal secretion from the stomach and

of the excessive secretion from the womb. The irritation of the extreme branches of the nerves of the intestines being conveyed to the trunk of the sympathetic, affected the more important function of the womb, while the atony induced by this continued excitement produced want of tone and constipation. The metallic tonic, combined with the conium, effected a gradual cure, not by any aperient effect, but by lessening undue irritation, and strengthening the muscular fibre. Cases 1 and 4 show the effect of severe shocks to the uterine system upon the intestinal canal—that irregularity of function, as well as malposition, produce by irritation a corresponding irritability on organs apparently remote. Case 2 is an ordinary case of continually-recurring dysmenorrhœa, gradually inducing irritability of intestine, leading to habitual dyspepsia and obstinate constipation.

I have endeavoured to make these remarks as practical as possible, anxious only to induce my professional brethren to make trial of a remedy which has, I think, fallen undeservedly into disrepute. I have curtailed the long relation of cases, presenting only their more salient points. I hope that I may induce observers more able than myself to study the interesting phenomena presented by abdominal and pelvic reflex actions, that they may be induced to believe that the notion, which has almost grown into an axiom, that women are more liable to constipation than men, because their pelves are more capacious, may be converted into the fixed rule, that this arises not from contiguity of position of organs, nor from the size of the pelvis, but rather from irregularity of function of the organs which are therein contained.

Bath, Nov. 17, 1851.

ON THE TREATMENT OF ARTHRITIC HEADACHE.

By WILLIAM HARVEY, Esq.,

SURGEON TO THE ROYAL DISPENSARY FOR DISEASES OF THE EAR.

In my last paper I endeavoured to point out the distinction between rheumatic and arthritic headache, showing that in the former the headache succeeded an attack of rheumatic inflammation of the structures of the ear, whereas in the latter the head becomes affected primarily, and the ear subsequently. Having also described other diagnostic symptoms peculiar to each, I now proceed to speak more fully of the treatment of arthritic headache. I have already alluded to the value of colchicum, in small and repeated doses, in those forms of the disease which are marked by tinnitus aurium and intermittent otalgia, as the result of gout in the cerebral mass. This medicine requires, however, judicious regulation; and not less important is the rigid attention to the hygiènic rules advanced by recent authors on that subject, more particularly attention to the skin during its administration, combining with the colchicum antimonials and occasional vapour baths, the latter, I think, the more preferable. Dr. Todd's views on this point are so practical and important, and so accordant, for the most part, with my own experience, that I may be excused introducing them to the reader.

Colchicum should not be given in the asthenic form of gout.

Colchicum should never be given at the onset of a paroxysm, nor until the bowels have been duly acted upon by mild purgatives.

The first doses of the medicine should be very small; they may be gradually increased.

Colchicum should be always administered at first, uncombined with any other medicine, until the practitioner has satisfied himself that it is not likely to disagree with his patient; and indeed there is always a disadvantage in administering this medicine in combination with others, since it may become difficult, if not impossible, at times, to determine what effects should be ascribed to the colchicum, and what to the other ingredients.

It should not be administered so as to excite nausea, vomiting, or purging. These effects should be regarded as indicative of the unfavourable operation of the medicine.

Colchicum may be regarded as acting favourably when, under its use, the urine is increased in quantity, a more abundant bile is discharged, when the fœces, though solid, are surrounded by mucus, and the skin secretes freely.

The effects of colchicum should be carefully watched, as, like digitalis and other medicines, it is apt to accumulate in the system.

The use of this medicine seems chiefly applicable to the sthenic form of gout, which occurs in robust constitutions, and in the prime of life, but it is almost inadmissible in persons advanced in years, who have had several attacks, and in whom the malady would seem too deeply rooted to be influenced by the temporary administration of this remedy.

These aphorisms may not only be taken to be true in the limited extent to which Dr. Todd has applied them, but even in old age, with judicious management, I have found the medicine equally useful and necessary, with this reservation, that the doses should be so regulated as not to depress the system in any sensible degree.

The presence of this acid, or of its base—urea, in the blood of gouty people, may be said to be principally characteristic of this specific form of headache, if I may use the term; and if the uric element be not removed by appropriate treatment, the disease will most probably terminate in serious disordered action, either in the brain itself, causing the arthritic apoplexy, or else by a kind of repercussive metastasis, in the joints or organs usually affected by gout. The value of this medicine appears, indeed, to be better appreciated in proportion as its eliminative action on the kidneys is prominently kept in sight. In the November number of this journal Dr. Hughes Bennet has written some interesting observations on its influence in connection with other diuretics, in that species of coma which occurs as a sequela of scarlet fever. This appears, indeed, to be

more readily explicable of the sedative influence of this extraordinary medicine than the attributing to it a primary action on the nervous system. It likewise assists in explaining its happy influence as an anodyne, which is often observable *after* its diuretic action has commenced, and not before. The oppression of the brain, which produced restlessness, and a sense of weariness, is relieved by the separation of the urea from the blood, which had previously acted as a poison to the brain.

In the earlier part of my remarks on this disease I have alluded to the risk attending the use of depletory measures in the treatment of this variety of headache, the injurious results which follow from the practice may be taken as one indication of the true nature of the disease under which the patient is labouring, when, as sometimes happens, an error in diagnosis, and consequently in the treatment, has been inadvertently made. The following case is a type of the primary seizure, and the result which follows :—

Case.—John B——, 43 years of age, a butler in a nobleman's family, was admitted a patient at the dispensary last spring. He stated that he had been suffering from severe headache, more particularly at the upper and back part, and a fulness in his ears, causing at times an imperfect hearing, and vertigo. His medical attendant, thinking it to be a threatening of apoplexy, advised bleeding and other evacuants; he was accordingly bled ad deliqium, but relief being only temporary, and the symptoms afterwards becoming more severe, the operation was repeated, with the effect of relieving him for one or two days only, other constitutional symptoms setting in obliged him to keep his bed. After some days he had a severe pain in his foot, his headache and giddiness being considerably relieved. He was shortly afterwards seized with an intense pain in the lobe of his ear, accompanied with swelling and redness; this continued to enlarge, and remained swollen for upwards of a month, and suddenly subsided; his head, in the mean time, was relieved, and he returned to his duties. Two months after another attack, resembling the first, caused him to repeat the treatment, with the like unsatisfactory result.

I saw this man shortly after, complaining of a heaviness in the side of the head on which the ear was affected, a continuous and distressing noise, aggravated towards evening, and an occasional pain, resembling a tic, on the side of the face and behind the ear. On inspection the structures presented nothing very remarkable beyond a dryness of the meatus, and a slight duskiness of the membrane of the tympanum; the hearing distance only two inches on the diseased side.

The treatment pursued was the administration of half a grain of the extract of colchicum, twice a-day, a vapour bath three times a week, his diet regulated accordingly, no stimulants, and less animal food than he had been accustomed to. The case progressed with but little relief for ten days, excepting only that he became more tranquilized as to his feelings of nervousness, and a copious perspiration over the skin. He continued the colchicum for six weeks, with the gradual diminution of the tinnitus, and a considerable increase of the hearing distance.

It would be useless to continue the narration of this case further, the patient perfectly recovered after a period of six months, not only of the hardness of hearing, but of a troublesome scaly eruption with which he had been tormented for some years. The aggravation of symptoms after the bloodletting is too demonstrative of the injurious effects of depletion, and evidently and forcibly points to the caution necessary in all such cases when any large quantity of blood is drawn from the system.

Case.—Colonel C., a corpulent and elderly gentleman, consulted me for a troublesome and heavy beating in his head and ears, always aggravated after meals, suffers from pains in the knees and ankles, and from some difficulty in swallowing, arising from a thickening of the mucous membrane of the pharynx, and some enlargement of the tonsils. When any freedom is permitted as to his appetite, the throat appears stuffed with a thickened mucus, and generally imperfect hearing, the meati on both sides were choked up with a deposit resembling gypsum, and although cleansed, repeatedly re-formed, accompanied with a discharge, leaving the meatus reddened and the membrane of the tympanum slightly opaque. These appearances I have so fully explained in a former paper "On Arthritic Inflammation of the Ear," both in the acute and chronic conditions, that it will be needless again to recur to them.

This gentleman was advised to pursue a course of treatment resembling the former case, with the exception that he commenced by active cathartics for ten days. The course of treatment was continued for a period of nine months, with marked relief both to the chalky formation in his ears, and the threatened suffocation which he has been for years suffering from. These cases are not unfrequently presented with the thickened mucous membrane of the throat, causing a temporary obstruction to the Eustachian passage. Although freely relieved by catheterism, this tube does not remain long patent, and the case seldom does well without the adoption of the constitutional treatment before alluded to in these cases. Nevertheless, when the patient's sufferings are very great, and urgently demanding relief, I have found the internal exhibition of colchicum to be the most efficacious palliative; care should be taken, however, to direct its operation on the bowels early, either by small and repeated doses of sulphate of magnesia or the acetic extract of colchicum, which I prefer, in combination with colocynth, the circulation at the same time being attracted to the feet by mustard pediluvia. I have stated that it is not uncommon to find as a result, in many cases of arthritic headache, that the patients are seized with an obstinate discharge from the ear of one or both sides, more frequently of one, this discharge I have examined from time to time, and if allowed to dry on paper presents some of the earthy concretions; it is in these cases that colchicum will be found extremely beneficial. As a rule, these discharges should be encouraged, and if any application is used locally, none answers better or gives to the

patient a greater amount of relief than cleaning the meatus occasionally with warm water. "I know, (observes Otto in his Pathological Essay,) a person in whom, during an atonic attack of gout, the whole mouth, throat, and gullet, are largely covered with a whitish mucus, which, when dried on blotting paper, left behind a large quantity of phosphate of lime. These tophi, as they are more commonly called do not consist as was formerly supposed, of the phosphate, but of the urate of lime, that is of uric acid, which we have spoken of as the probable proximate cause of gout, when it exists in the blood, and of lime in combination. This has been ascertained by chemical analysis, and taken with the preceding facts, may aid in explaining the causes and nature of gout in all its varieties. Further evidence in favour of this view is afforded by the fact, that during the decline of every fit of gout, uric acid or a salt consisting of that acid, with a base, generally ammonia, is largely deposited from the urine, and we also find that the use of alkalies and other antacids, which have an indefinite influence in diminishing the formation of urea, and in causing its elimination are at the same time among the best preventives of an attack of gout. All other facts tend greatly to show that the theory that gout is dependent on the presence of uric acid in the blood for its proximate cause, or at least that it is in some way connected therewith, if not absolutely demonstrated, is at all events far advanced on the road to direct proof.

This theory, however, is not altogether novel. The ancients had a glimpse of the truth, but only a glimpse. Their views were necessarily very crude and unsatisfactory, for want of the knowledge with which the vast and extraordinary progress made in animal chemistry of late years has so amply furnished us. They believed in the existenee of a morbid fluid in the system, as causative of gout, but were utterly ignorant of its nature and character. This doctrine prevailed in a somewhat modified form, during the existence of the humoral pathology; but when that failed these different views respecting the causes of gout were put forth. Of late years, again, the dogma teaching that the fluids in the system may be partakers in disease, as well as the solids, and may even be connected with the causes of constitutional and hereditary maladies, revived; and with it was revived the theory that referred gout to a morbid condition of the blood, or, in other words, that placed gout in the category of the blood diseases.

M. Bayle some years ago, published an essay on gout in the *Revue Médicale*, in which, when treating on the causes of the disease, he says they are unknown; but after carefully examining the pathognomonic symptoms, he is inclined to refer them to an alteration of some one of the humours, or as the result of a particular morbid fluid, produced under the influence of certain causes, and circulating with the other fluids in the economy. He especially mentions the occurrence of chalk stones as leading him to form this opinion; but probably he was not aware of their chemical composition, and therefore did not advance further than the threshold of discovery. Nevertheless, he believed that the morbid fluid, whatever it was, circulated in the blood; and, in confirmation of that view, cites the somewhat apocryphal case recorded in the "Nuremburg Commentaries," where it is gravely stated that blood drawn from the arm contained small gravel! Later investigators have referred the proximate causes of gout to the presence of a morbid element in the blood; but it was reserved for Garrod to discover what that morbid element was. He distinctly ascertained that during an attack of gout the blood always contains uric acid, and that that body can be crystallized from it in the shape of urate of soda, the acid being either much less in quantity or altogether absent from the urate. Dr. Bence Jones has since confirmed Dr. Garrod's statement, the results of his own experiments having satisfied him as to their correctness. Murray Forbes had, however, so far anticipated him as to have promulgated the opinion that the morbid material poisoning the blood was lithic acid; but he did not support his views by direct experiment, and, consequently, it is to Dr. Garrod that the profession is indebted for the elucidation of this important and interesting subject.*

WHAT OUR ASSOCIATION MIGHT DO.

By C. RADCLYFFE HALL, M.D.,
Torquay.

For the "Provincial Medical and Surgical Journal."

No. III.

Having considered the attitude we might take in regard to quackery, let us next inquire how we may improve our present one in regard to medicine. If we can find not a single positive excellency in homœopathy, we must not disguise the weak points in legitimate medicine. And first, of our shortcomings in the daily routine of practice, for which the practitioner and not scientific medicine is responsible. It were difficult to prefer an indictment against ourselves that should neither exaggerate nor underrate; and it is quite unnecessary to make the attempt. Our end will be sufficiently gained by directing attention to a few points wherein we might accommodate ourselves somewhat more than heretofore, perhaps, to the temper of the times, without infringing upon what is due to self-respect or to our patients. It need scarcely be stated that these points lie quite upon the surface. Expressly intended to raise the ordinary style of practice in the estimation of the public, to disabuse the public of some of their prejudices, and to remove some of their commonest objections, as these

* "I have stated," says Dr. Graves, in his Clinical Medicine, "that gouty affections of the brain have long been known; and I am not sure that some of the older authors may not have alluded to gouty affections of the spinal marrow; but as our knowledge of the peculiar state of the brain and spinal cord termed ramollissement is comparatively recent, and not dating with any degree of accuracy earlier than the works of Abercrombie, Roston, and other modern authors, it is obvious that any observations made by the older writers concerning gouty affections of the nervous centres can have no distinct reference to this lesion."

prejudices and objections, however deep and influential, refer only to what is superficial, inasmuch as they refer only to what is intelligible to persons ignorant of medicine, hints for our guidance cannot be very profound.

It may be that the following directions are superfluous, and are not required by any amongst us to be expressly laid down as ordinary rules of practice.

1. Never prescribe medicines when hygèine will do as well and can be enforced.

2. Never permit the patient or those around him to expect more from medicines than medicines can perform.

3. Never prescribe medicines, except avowedly as mere palliatives, when the period is gone by for them to be of ultimate service.

4. Never conceal the *general* intention of the treatment; *i.e.*, whether it be adopted with a view to cure, or only to mitigate the disease, or merely to alleviate a symptom or symptoms.

5. Never prescribe medicines more powerful than are necessary; or continue a powerful medicine longer, or repeat it oftener, than the disease actually requires.

6. Never attribute to the medicine-giving part of the management of a successful case more than its due share of credit.

Never to prescribe medicines when they can without disadvantage be dispensed with, is by no means the easy rule to be observed that it seems. Confidence in the work of Nature unaided by its time-honoured handmaid and namesake Physic, requires a species of abstract faith more difficult to meet with than faith in the physic itself where the object is palpable.* Medicines may not be needed for the disease, but they may be for the patient. Distrust would hurt him, and of nature alone he is distrustful. The rule, therefore, cannot be made absolute. But as often as it can be adopted it should. By degrees, the doctrine will work its way, that medical attendants are required to survey, superintend and direct disease, to watch lest harm accrue unnoticed, to employ active remedies when required, or not to interfere at all, as seems to their own judgment best. Every case of successful treatment without medicines will assist to indoctrinate the public with this view. By learning how much Nature can do without medicines, people will be able to perceive more correctly how much medicines, when they are necessary, can assist Nature. Witnessing for every case of recovery after globules, a parallel case of recovery without medicines of any kind, homœopathic patients will by degrees accept the truth. Most forms of quackery are killed by a newer and more plausible species. The old description is superseded by the new. Homœopathy, however, is so specious and so outrageous, that it would indeed be a clever piece of new quackery that should despoil it of its charms. Truth must kill it.

And must we, as a consequence of so raising the veil, sink in estimation, in occupation, or in remuneration? Without arguing that the question, being one of principle, is not to be decided by such a consideration, we answer unhesitatingly that we need not fear any such result. Every patient sensible enough to permit the treatment, will be sensible enough to appreciate him who directs it. Medical attendance can never be dispensed with. Natural solicitude in most, and an occasional error of judgment in the rest, will effectually ensure that. On the other hand the advantages are real. Every indisposition which is recovered from as well without medicines as with, is recovered from better without than with. The homœopathist tells his patients that by taking his infinitesimal doses until they are cured, they are spared the debility and wear and tear of system produced by what he nicknames the Allopathic mode of treatment; and that they will have less ground to make up. And *when* the case happens to be such as will do well under hygiènic treatment alone, without medicines, unquestionably he is right.

"Verily, there is nothing so false, that a sparkle of truth is not in it."

Of all recommendations, this is the one which has most influenced the sensible non-professional adopters of homœopathy. Such persons can be taught only *by examples* that the cases will recover just as well without globules as with them.

If any one doubt the extent to which a patient will mislead himself in judging of what affects his own body, be it a globule or aught else; or, the extent to which confident assurance will produce a predicted result; let him consider the facts which are mixed up in the fictions of the so-called electro-biology. These facts and ordinary medical experience conspire to show how great is the importance of confidence on the part of the patient in the effects promised by his attendant, and how happy a gift for the homœopathist is the possession of a due share of modest assurance. In pitting hygiène and nothing, against hygiène and the globules, in the

* This feeling is by no means restricted to medicine. It is natural, instinctive, and universal in its application. All little-cultivated, or rather little-exercised minds—and they constitute of course the great majority—are quite unable to believe anything that does not furnish them with an appreciable object of sense either past or present. Hence, in the History of Religion we find that the first phase has always been Idolatry. If we may without impropriety refer to things sacred, we find the highest illustration of accommodation to this requirement of the human mind in the Divine scheme of Religion, arranged as it is to meet the necessities of all men for all time. In the Saviour, Christianity presents an object impersonate, on which all may build their faith. Without such an object, teaching by example as well as by precept, the great bulk of mankind would be incapable of realising the perfect exercise of faith at all; and to every one faith is easy in proportion as it is more objective, less abstract. This is not mere matter of theory or of metaphysical inference. It has been put to the test of experience. When Robespierre, alarmed at the political results of an open denial of all religion, caused pure Deism to be preached in the churches of Paris; after the novelty wore off, congregations would not attend. The people could feel no faith in abstractions. When the first missionaries to Greenland preached Natural Religion (*i.e.* Abstract Religion) they excited little attention and made no converts. So soon as they began to preach Christianity, and thus to furnish an object which was intelligible to the untutored minds of their hearers, the difference in result was great and striking. But it is in the time of greatest need when reason is failing in its power, when the strong mind becomes weak, in protracted sickness and at death, that we perceive most forcibly that instance amongst so many of the perfect adaptation of Christianity to our nature, which consits in its not merely explaining and commanding faith, but in furnishing us with an object of faith cognizable to the senses once, and to the mind's eye for ever. The natural history of Human Faith, its extent, its limitations, and its laws; illustrated in its abuse, by the evils of superstition, the absurdities of credulity, and the unreasonableness of scepticism; and, in its use, by support under trial, comfort in sorrow, and happiness in the exercise of it; has yet to be written. In such a book, how large a page must be devoted to quackery in Law, Physic, and Divinity! And it could not be otherwise. To expect to have the uses of faith and not its abuses, would be to expect to have one part of our moral nature, and that the highest, perfect, when all the rest is imperfect.

management of suitable cases of illness, the legitimate practitioner must maintain the confidence of his patient in the mode adopted, as fully as the homœopathist does; otherwise, the conditions are not the same, and the potent influence of the *morale* will support the one and oppose the other method, and nullify the trial for all purposes of comparison.

The cases and the circumstances in which hygiène may be trusted to, exclusive of medicines, must be left entirely to the discretion of the attendant, who will seldom be at a loss to decide when he may be the careful looker-on, and when the energetic actor; when he must oppose the enemy like Fabius, or conquer him like Hannibal. As an example, we adduce the following every-day occurrence:—A child, above the age of infancy, is chilly, looks dull around its eyes, has headache, pain in the back, quick pulse, and no appetite. It is not known that the digestive organs have been over-taxed. The case may prove—anything. A local inflammation not yet made manifest by local pain; the commencement of continued, or remittent, or exanthematous fever; in a word, there is scarcely any ailment of children of which this may not be the commencement. *If*, on careful examination, no local disease can be made out, we have no correct indication for special treatment. Give Nature fair play. Put the child into a warm bed in a warm room, keep it quiet, stop the supplies of food, but not of water, and wait. When reaction takes place, if there be anything serious it shows itself, and we then know what to attend to. Very frequently, the case is one of mere ephemeral febrile disorder, from exposure to cold; and in two or three days the child is perfectly well again without having taken either medicines or globules. But have we done nothing? When the heart was striving to restore the balance of the circulation, by adopting the recumbent posture we gave it less work to do. The equable warmth of bed was soothing to the nervous system, and solicited the afflux of blood to the surface. By abstinence, we avoided ministering to congestion of the viscera, and introducing food which, as it could not be properly digested, would decompose and irritate the stomach and bowels. We have not thwarted Nature; in a measure, we have assisted her. She has done her own work, and done it well. The convalescence in such a case does not exist. Treat the case in the same way *quoad* hygiène, and give globules. The result is the same. The only difference being that the credit is now given to the globules, and considerable respect and gratitude are felt towards the talented and ingenuous Globularius. Treat the case with an emetic, a dose of calomel and saline mixtures, and at least there will be a stage of convalescence to be passed through.

It is in such a case that the homœopathist "cuts short" an attack of fever, or "prevents it from passing on into typhus!"

In all chronic blood-diseases, medicines are useful, but hygiènic treatment must rank the first. In all acute blood-diseases, when mild and occurring in a previously healthy constitution, as they must run through a special course and last for a certain time, cases will frequently do very well without any medicines. More frequently, a little medicine occasionally to meet a temporary requirement is serviceable; but in every case of this kind, however severe, the difficult point of medical judgment is, rather, when to do nothing, than what to do. Hygiènic treatment is invariably necessary. Acting on the principle of the accoucheur, that Nature is to be carefully watched, but that so long as she proceeds well, she is to be let alone, we shall meet with few cases of illness in which we cannot find opportunities to judiciously dispense with medicines.

And if we openly make it our rule of practice as far as possible to dispense with medicines, will the public begin to dispense with us? This consideration is low ground to take, but the reality and importance of its influence must be our excuse for again reverting to it, and for answering it emphatically in the negative. Do the public dispense with the accoucheur because they are quite aware that in many cases, his scientific interference with Nature will not be needed. His scientific knowledge and experience are always needed to give confidence in Nature's work, the assurance of safety, and to prevent mistakes. It occasionally happens in the experience of the country practitioner, that some farmer's wife glories in the number of olive branches she has attached to the family tree without the aid of the accoucheur. Fifteen children born without the doctor! and at her sixteenth confinement she dies of flooding. The occurrence affects the Œsculapius of the neighbourhood, very much as an occasional fire affects an insurance office.

No. The old adage concerning the man who is his own physician expresses the public sentiment as well as our own. Moreover, the reply to the question is given already by the custom of those who employ homœopathic advisers. According to the doctrines of homœopathy, he cannot err who administers the proper globules for the given symptoms. The knowledge of pathology, physiology, or anatomy, is entirely unnecessary and superfluous. Symptoms alone guide the treatment, and therefore symptoms alone require attention. Now, in the *ad captandum* books on domestic homœopathy, the symptoms and their remedies are so clearly and explicitly laid down, that he who reads may learn. Any one suffering from "a Cough," for instance, may ascertain immediately by considering its particular accompaniments, whether he must take decillionths of a grain of "aconite, belladonna, chamomilla, hyoscyamus, ignatia, ipecacuanha, nux vomica, pulsatilla," or "arsenicum." It is true he may be a little puzzled to find some of the same (*similia similibus*) remedies enumerated as proper for chilblains, measles, erysipelas, nettle-rash, epistaxis, croup, quinsy, diarrhœa, infantile convulsions, and maternal milk-fever; but still none of these complaints are just now any concern of his, and the directions for treating his own disorder of "Cough" are so clear and precise, and each remedy has power over so many different symptoms, that, guided by the book, the selector can hardly go wrong. Indeed the effect of the given globule appears to depend entirely upon what is required to be

done; fulfilling the intention of the prescriber, whatever that may happen to be. As the patient, if his own doctor, can have but one intention in prescribing, of course the globules he may take can scarcely avoid curing him. "Sometimes," however, this patient must remember, "homœopathic remedies, even when administered in strict accordance with the homœopathic law, cause an aggravation of the symptoms." (Epps; p. 272.) Again, it must be admitted that cases do occur in which the patient ought not to prescribe for himself, or the parent for his child. For we read,—"No parent is justified in treating hydrocephalus; the physician's (*i.e.*, the homœopathist's) aid must be sought: and I (Epps *loquitur*) can add, from an extensive experience, that the homœopathic physician's aid is very often *successfully* sought: a result rarely, if ever, obtained under allopathic treatment." Still, in the majority of cases, provided he be not too ill to think, or rather to read, nothing can be more easy than for a homœopathic patient to prescribe for himself. Yet he rarely does so.

We must not in justice conceal that there may certainly be some reasons to prompt a believer in homœopathy to send for his adviser, which could not operate upon our patients. Thus, we may imagine a diffident patient in a fit of colic to refer to his book, and read that the proper remedy for colic, provided it occur "*in very mild dispositions*," is pulsatilla. As self-knowledge is at all times difficult, and as indisposition does not clear the perceptive faculties, the diffident patient may need his adviser to decide for him whether his is the colic that pulsatilla can cure, more especially since a mistake in regard to his own disposition might be serious, as this emphatic observation testifies:—"*Note.*—It is one of the peculiar features of homœopathic practice, that the *moral* symptoms are so highly important: in fact, in some cases deciding the use of a remedy. Precision is therefore one essential in successful homœopathic practice: and if precision is deemed a mark of a scientific mind, surely homœopathy, which requires such precision, is to be regarded as possessing a scientific character." (p. 205.) Surely; surely!

Again, we may imagine a homœopatbic patient of a logical turn of mind to feel a difficulty in understanding by himself how this same pulsatilla, for instance, can be a *homœopathic* remedy for so many diseases having different symptoms. He reads, as its definition, that "Allopathy (Αλλος, allos, another, and παθος, pathos, suffering,) is the doctrine that develops the principle that diseases are to be cured by inducing *other diseases in some parts of the system not already affected.*" Legitimate practitioners, he knows, have called their art and science allopathy: but the bill of fare was not tempting, so he has long since forsaken that. "Homœopathy (from ομοιος, omoios, like, and παθος, pathos, suffering,) is the doctrine that developes the principle that *diseases are cured most quickly, safely, and effectually by medicines which are capable of producing in a healthy person symptoms similar to those existing* in the diseases." (p. 241.) As an illustration, he finds that, "persons liable to toothache should abstain from coffee, toothache being one of the effects of *coffee.*" (p. 101). Accordingly, "coffœa," in an infinitesimal dose, is given as a cure for toothache. Thus impressed with the characteristics necessary for a homœopathic remedy, the logical patient looks through the list of symptoms of various disorders to find out his own, and discovers, in passing, that sulphur, in homœopathic doses is peculiarly efficacious in cases of of tape-worm. Now, as he knows that the only unmistakeable sign of tænia is the appearance of a portion of the parasite, the doubt arises—can sulphur in a large dose make a tape-worm? But, on the other hand, arsenic in homœopathic dose, he finds, is the remedy for the "fear of death;" and arsenic in large dose certainly does produce that symptom. He passes on, and is struck with the number of diseases having very dissimilar and opposite symptoms which pulsatilla, in homœopathic doses, will cure. Can pulsatilla in large doses, then, produce dissimilar and opposite conditions in a healthy body? If not, how can it be the *homœopathic* remedy for diseases which present opposite symptoms? He finds that pulsatilla is a homœopathic remedy in the following tolerable extensive catalogue of dissimilar ailments:—

Chilblain.	Hæmoptysis.
Measles.	Toothache.
Erysipelas.	Sore throat.
Nettle-rash.	Dyspepsia.
Inflamed wounds.	Vomiting, "when caused
Headache.	by food that is fat;"
Stye in the Eyelid.	Constipation.
Earache.	Diarrhœa.
Running from the Ear.	Colic, "in very mild dis-
Bleeding from the Nose.	positions;"
Catarrh.	Jaundice.
Bronchitis.	Inflammation of the Liver.
Cough.	Rheumatism.
Whooping-cough.	Varicose Veins.

The logical patient feels *l'embarras des richesses* Can pulsatilla, he asks himself, taken in any quantity whatever, really produce the symptoms of vomiting precisely resembling that "caused by food that is fat," in a healthy person who has fasted for some time previously, in order to give the drug "a fair field and no favour?" Can it really occasion the symptoms of measles? Can it make a healthy vein become varicose? Can it even cause a sound tooth to ache? And if it cannot do all these things, it cannot really be the homœopathic remedy for all these disorders. And if not for all, for which?

And on further reflection, can *any* drug or substance whatever, in *any* quantity whatever, really produce the symptoms of measles, scarlatina, small-pox, or typhus? or those of hydrocephalus, pneumonia, or peritonitis? Unless the answer be in the affirmative, there can be no *homœopathic* remedies for these complaints. But in what part of the book are the proofs? Is the recovery of patients after taking the assumed homœopathic remedies the only proof? It is all the logical patient can find as such. Then homœopathy did not

begin with Hahnemann. Two hundred years ago and more, patients with scarlet fever were treated by hanging the bed and bed-room with scarlet drapery, and they recovered after it. Doubtless, because the remedy produced the characteristic symptom of redness of the skin. And from time immemorial our rustics have cured jaundice with saffron tea, which if applied to the skin in considerable quantity would produce the symptom of yellowness. But, on the other hand, sometimes when owing to circumstances, no remedies whatever have been administered, patients have recovered equally well from scarlet fever and from jaundice. If, then, this fact of recovery be the sole proof,—1st, of the power of the remedy in large dose to produce the symptoms; and, 2nd, of the power of the remedy in infinitesimal quantity to remove the symptoms, and cure the patient; it is equally strong in proving in both these senses the potency and efficaciousness of *nothing*. Potentially are they one and the same?

"Quantum erat, ut sineres *hos* toto corpore jungi."

Again, has any *proof* ever been given that a millionth or a decillionth part of a grain, does possess more of the properties of the remedy than the whole grain? Will a drop of laudanum procure sleep like a hundred drops? Will a drop of hydrocyanic acid, of the ordinary strength, kill like a thousand drops? If not, the increased potency of infinitesimals can only commence when the particle of matter is too minute to be recognizable, and therefore too inappreciable to be submitted to proof. But does not the drug obtain some new power from the friction and shaking to which it is subjected in the preparation of infinitesimal doses, and so obtain a curative property, which in larger quantities it did not possess? Are not the globules *dynamized?* But if the globule cures the disease because it has gained something by dynamization which it did not possess before, then it does not cure in accordance with the fundamental principle of homœopathy. Not having the property whilst in large quantities, which renders it efficacious after infinitesimal division, it is virtually two things in the two conditions; one thing in large quantity, a different thing when dynamized in small quantity. What, then, becomes of the "law" of *similia similibus?* It is not one remedy to cause and the same to cure the disease, but virtually one to cause and another to cure. But, granting that this dynamization does transgress the great law of homœopathy, that is not an insuperable objection. Certainly not. Then *prove* the dynamization. Will ten shakes of a vial make one drop of laudanum as powerful as a drachm, or give to it any appreciable new quality? Will six rubs and a half make a twentieth part of a grain of aloes as potent as ten grains, or confer upon it any ascertainable fresh property?

Unable to reconcile his doubts with his preconceptions, the logical patient is more confounded than at first: like the reader, he is tired of the subject; he ceases to think, feels a heightened respect for the mind which can master what his own cannot, falls back on infallibility, and sends for Dr. Globularius.

Of the three doctrines of homœopathy,—*similia similibus curantur*, the power of infinitesimal quantities, and the dynamization of the globules, the last refutes the first, and the second must be exposed by illustrating on mankind the logic of Puff in the *Critic:*

"If the cure is very great when the dose is very small,
It must be greater still when the dose is none at all."

We may rest assured that how much soever we can with justice dispense with medicines in the treatment of disorder and disease, the patient will still require and appreciate our aid. The public will learn by degrees to trust more to the judgment of the individual medical attendant, and somewhat less to the medicines he prescribes. Such a consummation might be greatly hastened by the efforts of each member of our Association.

Provincial Medical & Surgical Journal.

WEDNESDAY, DECEMBER 10, 1851.

It has always been our earnest endeavour that no injustice should be done through our pages to the reputation or personal feelings of any individual. We therefore lose no time in correcting the erroneous impression which a notice in our last number might give rise to, as to the circumstances under which Dr. Holland was induced to hold professional intercourse with an avowed homœopathic practitioner. We then simply announced the fact that such intercourse did take place, appending such comments as we at the time thought deserved, but we are now with pleasure enabled to assure our readers, from Dr. Holland himself, that he had no *intention* whatever to act otherwise than in accordance with the strict line of medical morals.

It appears from the tenor of a communication with which we have been favoured, that Dr. Holland, when summoned from London, did not know whom he was going to meet, and that when informed of the character of the practitioner in attendance, begged it to be understood that he felt himself in a difficulty, stating at the same time his convictions respecting homœopathy. He also informed the friends of the patient, that in seeing the globulist, which he did next morning, and which he considered it was his duty to do, to obtain details as to the antecedents of the case, he wished it to be fully understood that he examined and prescribed for the patient on his own responsibility. It is clear, therefore, that Dr. Holland did what he

thought right under the circumstances, and did not consider that he was compromising either his own reputation or the honour of his profession. To so much we gladly bear testimony.

But while we thus perfectly exonerate Dr. Holland from any wilful indifference to the ethics of the profession, of which he has always been considered an ornament, we cannot admit that his conduct was judicious. Although *he* doubtless considered that there was no resemblance to a consultation in an interchange of remarks on the case at the bed-side of the patient, and although he particularly begged the friends not to consider it in that light, the public, as might have been anticipated, have done so; and the homœopath, we are given to understand, has studiously fostered the idea among his supporters, not only that Dr. Holland consulted with him, but that he—what we know to be untrue—also approved of his treatment. This, however, only shows the false position an honourable man places himself in by allowing his name to be mixed up with persons of this stamp, for there is nothing they more anxiously seek, than to entrap a regular practitioner into a communication with them, knowing that if he can be prevailed upon to discuss a case in the sick room, they will be able to boast of equality with him.

We are far from presuming to dictate to any one, much less to a gentleman of Dr. Holland's standing in the profession, what his course should have been in the present instance, and should be in any future case; but we will not disguise our own opinion, and from numerous communications on the subject, we know it to be the general one, that it would have been in all respects the proper course to have refused *all communication whatever*, with a professed homœopath. We know many London physicians who would have done so, and provincial practitioners in general know them, and doubtless do not forget to show when opportunity offers, that they appreciate their straightforward courage. Any indecision of conduct, let the intention be ever so pure, does but neutralize the intended effect, if it does not positively encourage the quackish proceedings which it is a sacred duty in every upright practitioner to denounce.

We here quit this painful subject, hoping most sincerely that we may never again be called upon to notice a case, in which, however good the object sought may have been, the results are so little satisfactory. The inference, however, is inevitable, that some more stringent line of demarcation must yet be drawn between legitimate medicine and the hundred and one *pathies* and other quackeries, which have been engendered in the prolific hot-beds of ignorance, credulity and avarice. The several Colleges must be roused to a due sense of what is expected of them by the profession whose honour they are sworn to protect, and to them we still look for such proceedings as shall compel their members to dissociate themselves either from quackery or from their communion. If they refuse to do this, and it be proved that they have the power to act, they will be alike unworthy of support or reverence.

Among other topics to which our attention has been called since our last publication, is the astounding fact, that Dr. Calvert Holland, who, after various metamorphoses has at length appeared as a full-blown homœopath, is allowed to call himself Physician Extraordinary to the Sheffield Infirmary. It is certainly very extraordinary of the ordinary medical officers, that they demean themselves so quietly under the insult—for insult it is whether they feel it or not—that an open abettor of quackery should be allowed to boast a title, of which he ought long since to have been indignantly deprived. We have not the pleasure of knowing who the ordinary Medical Staff of the infirmary may be, but if they feel any difficulty in shaking off their obnoxious colleague, through the stolid indifference of hospital governors, our advice to them is to resign in a body. We are much mistaken if this proceeding would not speedily induce a satisfactory attention to their wishes.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DRAFT SUPPLEMENTAL CHARTER.

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, To all to whom these Presents shall come, Greeting.

Whereas the body politic and corporate of the Royal College of Surgeons in London was incorporated or re-established under or by virtue of a certain Charter or letters patent, bearing date at Westminster, the twenty-second day of March, in the fortieth year of

the reign of King George the Third, or otherwise as in such letters patent mentioned or referred to, and further powers and privileges were granted to the said College by a certain other or supplemental charter granted by letters patent, bearing date at Westminster the thirteenth day of February, in the third year of the reign of King George the Fourth. And by our letters patent, bearing date at Westminster the fourteenth day of September, in the seventh year of our Reign, the name or style of the said College was altered to "The Royal College of Surgeons of England," by which name or style the said College is now called or known, and divers further powers and privileges were granted to the said College by our said letters patent: and the said College is now regulated and governed by and according to the provisions of the said several charters or letters patent, and also by or according to certain bye-lays and ordinances made by the said College for its regulation and better government: and whereas the body politic and corporate of the said College at present consists of persons created members of the said College, by the said first-mentioned charter, or constituted such members by letters testimonial under the common seal of the said College, of the respective qualifications of such persons to practice the art and science of surgery, and also of persons created fellows of the said College under the provisions of our said letters patent, and elected and declared to be fellows of the said College by one general diploma, under the seal of the said College, enrolled in our High Court of Chancery, and also of other persons appointed under the powers of our said letters patent, by the Council of the said College, to be fellows of the said College by diplomas under the seal of the said College, and also of other persons, who, after having attained the age of twenty-five years, and complied with the rules and regulations directed by the bye-laws of the said College, and having passed a special examination by the examiners of the said College, have been admitted fellows by diplomas under the seal of the said College. And the governing body of the said College consists of a Council of twenty-four persons, some of whom, being members of the said Council at the date of our said letters patent, were thereby continued, and are life members thereof, and others of them are elective members of the said Council, chosen from the fellows of the said College in manner mentioned, and directed by our said letters patent, and hold their office for a limited period only, and one of such twenty-four persons is the President, and two of them the Vice-presidents of the said College; and the Court of Examiners of the said College consists of ten persons, some of whom, being Examiners at the date of our said letters patent, were thereby continued, and are such examiners for life, and others of them have been elected by the Council of the said College since the date of our said letters patent, and under the directions therein contained, and hold their office of examiners during the pleasure of the Council of the said College.

And whereas, it appears to us expedient that the right of admission to the fellowship of the said College be extended to such persons as were members of the said College at the date of our said letters patent, subject to certain conditions and regulations hereinafter mentioned, and that the Council of the said College have power annually to elect certain members of the College to be fellows, without examination, in manner hereinafter mentioned. That certain restrictions now existing upon the eligibility of fellows to be members of the Council of the said College be removed, and that certain other qualifications be required of fellows offering themselves as candidates for the Council. That certain alterations be made in the electing of members of the Council. That power be given for admission to the College as hereinafter mentioned of the fellows, members, and licentiates of certain other corporate bodies, as hereinafter mentioned. That certain alterations be made as to the continuance in office of all future examiners of the said College, and as to the continuance of the president in certain cases as a member of the Council, and that a Board of Examiners in Midwifery be established, as hereinafter mentioned. Now know ye, that we of our especial grace and mere motion, at the humble petition of the said Royal College, have willed, ordained, constituted, and declared and granted, and by these presents, for us, our heirs and successors, do, will, ordain, constitute and declare, and unto the said Royal College of Surgeons of England do grant in manner following, to wit,—

1. That it shall be lawful for the Council of the said College at any time or times hereafter, by diploma or diplomas under the seal of the said College, in such form as the said Council may think fit and direct, and without any previous examination, to appoint any person or persons who at the date of our said letters patent was or were a member or members of the said College of fifteen years' standing; and also any person or persons who, being at the date of our said letters patent a member or members of the said College of less than fifteen years' standing, shall have attained at the time of such appointment the standing of fifteen years, to be a fellow or fellows of the said College, subject to the regulations hereinafter mentioned and directed.

2. That the appointment of every person to the fellowship of the said College under the powers herein contained, shall be determined by the vote or ballot of the Council, and be decided by a majority of votes or balls, and that every such person seeking to be admitted to the fellowship shall transmit or deliver to the Secretary of the said College, at such time before the day appointed for the ballot or election as the Council may think proper and direct, a certificate, signed by such persons as hereinafter mentioned, of the moral character and professional attainments of the person applying for admission to the fellowship, and that he does not sell or supply drugs or medicines otherwise than in the due exercise or practice of his profession of an apothecary: and shall also at such time, so to be appointed as aforesaid, transmit or deliver to the said Secretary a declaration signed by himself, to the effect that he does not sell or supply drugs or medicines otherwise than in the due exercise or practice of his profession of an Apothecary; and such certificate and declaration shall be in such form as the Council of the said College shall from time to time direct.

3. That the certificate to be produced by the persons seeking admission to the fellowship of the said College, as last aforesaid, shall be signed by six fellows of the

said College; or in the case of persons absent from the United Kingdom in the service of our Royal Army or Navy, by two fellows of the said College, and by the Director-General or other officer superintending the medical department of the service to which such persons shall respectively belong; or in the service of the Honourable East India Company by two fellows of the said College, and by the secretary to the military department of the said Company; or in the case of persons resident in any of our colonies, plantations, or dependencies, by two fellows of the said College, and by the Governor, Lieutenant-Governor, or Superintendent thereof, whose signature shall be certified by our Secretary, or one of our Under-Secretaries of State for the Colonies.

4. That the fee to be paid upon the admittance of every fellow of the said College, to be appointed under the powers hereinbefore contained (over and besides any stamp duty on his admittance or diploma), shall be the sum of ten guineas.

5. That it shall be lawful for the Council of the said College, by diploma or diplomas under the seal of the said College, in such form as the Council may think proper, to admit to the fellowship of the said College in each and every year from the date of these our letters patent, without examination, but subject to such conditions and regulations as the said Council may think fit, and by any bye-law or bye-laws direct, any two persons, being at the time of such admittance members of the said College of not less than twenty years' standing; and that the fee to be paid upon the admittance of each such fellow as last aforesaid shall be the same as the fee payable upon the admittance of Members of the said College to the fellowship under the authority of our said letters patent.

6. That it shall be lawful for the Council of the College, by diploma under the seal of the College, to admit without examination to the membership or fellowship of the said College, on such conditions, and on the payment of such respective fees as the Council of the College shall by bye-laws determine, the fellows, members, and licentiates respectively of the Royal College of Surgeons in Ireland, the Royal College of Surgeons of Edinburgh, and the Faculty of the Physicians and Surgeons of Glasgow, provided such fellows, members and licentiates shall be, at the time of their application for admission, in the *bonâ fide* practice of the profession of a surgeon in England or Wales, and shall have obtained their respective diplomas or licences after examination, and such persons so admitted to such membership or fellowship shall take rank amongst the members or fellows of the said College, according to the date of such last-mentioned diplomas or licences.

7. That from henceforth no fellow of the said College who shall not have been a fellow of the same for fourteen years, or a member of the same for twenty years, and no fellow of the said College who at the time of election shall not be in the *bonâ fide* practice of his profession of a surgeon, or who shall be practising as an apothecary, shall be eligible as a member of the Council of the said College; but every fellow of the said College of such standing as a fellow or member of the same as last aforesaid, and who, at the time of such election shall be in the *bonâ fide* practice of his profession of a surgeon, and shall not be practising as an apothecary, shall be eligible as a member of the said Council, any restriction or disqualification in respect of the practice or residence of such fellow or otherwise in the said letters patent contained to the contrary notwithstanding. But if any member of the Council shall at any time after his election cease to be in the *bonâ fide* practice of his profession of a surgeon, or shall practise as an apothecary, he shall thereupon cease to be such member of the Council, and shall forfeit all his rights and privileges as such member thereof; and it shall be lawful for the Council of the said College to declare the place of such member in the Council to be vacant, and the same shall be filled up in the manner hereinafter directed respecting vacancies in the Council.

8. That all vacancies which shall from henceforth occur in the Council of the said College, either by reason of any of the Members thereof going out of office by rotation or from any other cause, shall be filled up in manner hereinafter mentioned on the first Thursday in the month of July in every year, or within one calendar month afterwards, unless at any time the number of members of the said Council shall be reduced below eighteen, in which case it shall be lawful for the Council of the said College to appoint such day for filling up the vacancies as they may think proper: and that the Council of the said College shall cause a notice of the day appointed for the election of members into the Council to supply the vacancies occasioned either by members going out of office by rotation, or by any other cause, and of the number of vacancies to be filled up, to be advertised in the *London Gazette* at such time as the Council shall from time to time direct, before the day appointed for such election, and shall also cause such notice to be published or announced in such other manner as the said Council may from time to time direct.

9. That every eligible fellow who shall intend to offer himself as a candidate for a seat in the Council of the said College shall within such time as the Council shall from time to time direct from the publication of the *London Gazette*, in which the day of election shall be announced, transmit or deliver to the secretary of the said College a notice signed by himself of such his intention, together with a nomination signed by six fellows of such person as a fit person to be elected into the Council, and a certificate that he is in the *bonâ fide* practice of his profession as a surgeon, and that he does not practise as an apothecary, which certificate shall be signed by three fellows of the said College; and the person so intending to offer himself as a candidate for the Council shall at the same time transmit or deliver to the said secretary a declaration signed by himself that he is in the *bonâ fide* practice of his profession as a surgeon, and that he does not practise as an apothecary; and such nomination and certificate, and also such declaration as last aforesaid, shall be in such form as the Council of the said College shall from time to time direct.

10. That no fellow shall have power to nominate at any one election any greater number of persons as candidates for the Council than the number of vacancies which shall be to be filled up at such election; and if any fellow shall at any such election nominate any

greater number of candidates than as last aforesaid, then such fellow shall be incapacitated from voting at that election.

11. That no member of Council shall go out of office by rotation whilst holding the office of President; and that as often as it shall happen that the President shall be one of the members who would at any annual meeting go out of office by rotation, two members of Council only, instead of three as prescribed by the Charter, shall be elected at such meeting—and that at the next annual meeting such member shall go out of office in addition to any other members of Council going out of office by rotation according to our said letters patent—but any member whose going out of office shall have been postponed as above provided, shall in case of his re-election into the Council on his going out of office at such succeeding annual meeting as aforesaid, on all future occasions go out of office in the same order as if he had been re-elected at the time when he would, but for this provision, have gone out of office.

12. That the Council of the said College shall cause lists of the names of all eligible fellows of the said College who shall in manner hereinbefore directed be nominated as candidates for the Council, and shall have complied with the provisions hereinbefore contained respecting the notice, certificate, and declaration to be transmitted to the secretary of the said College, as and together with the names of the fellows by whom they shall respectively be so nominated, to be published in the *London Gazette* and in two London daily newspapers, at such time before the day appointed for the election as the Council shall from time to time direct.

13. That henceforth, instead of the name of every fellow eligible to be elected being announced to the meeting in the order and according to the priority in which his name shall stand in the register of fellows, as directed by our said letters patent, the names of all fellows included in the lists so published as aforesaid, shall be announced to the meeting as the candidates for election.

14. That the names of the members of the Council who shall in each year retire from office by rotation, shall, if they shall be desirous of re-election, and shall intimate such their desire in writing to the secretary of the said College within such period as the Council shall determine before the day appointed for the election, be placed at the head of the lists of candidates to be published as hereinbefore directed; and that such persons, if re-elected into the Council, shall take precedence of all other persons who shall be elected in the Council on the same day, and shall with respect to each other take precedence according to their former seniority in the Council.

15. That any nomination and certificate or declaration hereinbefore required to be made or produced upon or previously to the election of any fellow into the Council of the said College, being transmitted or delivered in the manner hereinbefore required, the same (as regards the matters or particulars so to be certified and declared as aforesaid, but no further) shall be final and conclusive as to the eligibility of such fellow. But if it shall afterwards appear to the satisfaction of the Council of the said College, that any such nomination or certificate or declaration is in any respect untrue or fraudulent, then it shall be lawful for the Council of the said College to declare the member of the Council, to whom such nomination and certificate may relate, or by whom such declaration may have been made, to be no longer a member of the said Council; and thereupon every such member of the Council of the said College shall cease to be such member thereof, and shall forfeit all his rights and privileges as such member thereof; and it shall be lawful for the Council of the said College to declare the place of such member in the Council to be vacant, and the same shall be filled up in the manner hereinbefore directed respecting vacancies in the said Council.

16. That every fellow of the said College who shall from henceforth be elected to the office of examiner of the said College, shall go out of office at the end of five years from the day of his election; but that it shall be lawful for the Council of the said College immediately to re-elect such person to the said office, and every such person being so re-elected, shall take precedence in the Court of Examiners, according to his former standing as a member thereof.

17. And it is our further will and pleasure, that a Board of Examiners be appointed by the said College for the purpose of testing the fitness of persons to practise in midwifery, and of granting certificates of such fitness; and that such Board shall consist of not less than three persons. And we do hereby authorize and require the Council of the said College, within twelve months from the date of these our letters patent, to appoint not less than three persons to be such examiners in midwifery, who shall continue in office for such period, and shall conduct the examinations in such manner, and shall grant certificates in such form as the Council of the said College shall determine and from time to time direct. And it shall be lawful for the Council of the said College, from time to time, as vacancies shall occur in such last-mentioned Board of Examiners, to appoint any persons to fill up the same.

18. And we do hereby further declare our will and pleasure to be, that all and every direction, provision, regulation, clause, matter or thing whatsoever, in the said several recited letters patent of our royal predecessors and ourselves, or in any bye-laws, or bye-law of the said College, contained, which may be repugnant to or inconsistent, or at variance with the several directions, provisions and regulations herein contained, or any of them, in so far as the same are repugnant thereto, inconsistent or at variance therewith, shall be, and the same are hereby abrogated, repealed, and rendered of none effect. But that except in the respects hereby altered, the said College and the Council of the same shall continue to have all such, and the same jurisdiction, powers, authorities and discretions for and with respect to the government of the said College, and the election and choice of the officers of the same, as well as the admission and expulsion of members and fellows, and for the making, ordaining, confirming, annulling, or revoking bye-laws, ordinances, rules, and constitutions, and transacting and ordaining all other matters and things whatsoever, for the regulation, government and advantage of the said College, as such College and the Council thereof respectively now have, under or by

virtue of the said three several hereinbefore recited Charters or letters patent, or either of them respectively, or in any other lawful manner.

And we do hereby for us, our heirs and successors, grant and confirm unto them all such jurisdictions, powers, authorities and discretions accordingly.

And we do hereby for us, our heirs and successors, further grant unto the said College, that these, our letters patent, or the enrolment or exemplification thereof, shall be in and by all things, good, firm, valid, sufficient and effectual in the law, according to the true intent and meaning thereof, notwithstanding the not fully or not duly reciting the said several letters patent, or the dates thereof, or any other omission, imperfection, defect, matter, cause or thing whatsoever, the same or any rule or law to the contrary thereof, in anywise notwithstanding. In witness whereof, we have caused these our letters to be made patent.

Witness ourself at our palace at Westminster, this day of in the year of our reign.

Proceedings of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY AND HOMŒPATHY.

[The importance of the meeting, of which we now give an account, is incalculable, and must, we would fain hope, stir up the sister Society of London, to an equally vigorous effort. We admire particularly the manly honesty of Professors Syme and Simpson, and would recommend their example to certain great men in our own metropolis, who, for the present at least, shall be nameless.]

A full meeting of the Edinburgh Medico-Chirurgical Society was held on the 19th of November, no less than sixty-four members being present. After the transaction of routine business, the following interesting circumstances occurred :—

Professor Syme, in moving "*That the public profession of homœopathy shall be held to disqualify for being admitted or remaining a member of the Medico-Chirurgical Society,*" said,—that in addressing the Society on this occasion, he considered it to be quite unnecessary to enter into a formal refutation of the principles of homœopathy, but before proceeding further he would exculpate himself from the charge of inconsistency brought against him by Dr. Henderson, to the effect that he had himself countenanced homœopathy in two instances. This charge appeared at the time in the various medical periodicals. Now, regarding this inconsistency as tantamount to a practical falsehood, he (Mr. Syme) took the present opportunity of exhibiting the falsities of the accusation. The cases to which Dr. Henderson alludes are two in number. The fact is, there was a young man who had been under the care of Dr. Nimmo, and who had been placed under his (Mr. Syme's) care. Finding that he had been attended by Dr. Henderson, Mr. Syme requested a meeting, not for the purpose of consultation, but to arrange for placing the medical treatment under the hands of another physician, Dr. John Taylor, as Mr. Syme felt that he could not co-operate with Dr. Henderson. In the second case, he met Dr. H., being under no pledge not to do so. This is the whole extent of his countenance of homœopathy. Mr. Syme next stated what he conceived to be the duty of every member of the profession. As an individual, he had long refused to adopt homœopathy, because he regarded it as a mischievous folly. As a member of a licensing board he would not refuse any candidate who complied with the regulations of the University. If such an one were base enough to disguise his real sentiments in regard to the practice of physic, the disgrace would rest with him and not with the Board. The duty of a Society like the present, was, he said, clear. It was a voluntary Association for upholding sound principles of practice, and for elevating professional character. If, therefore, a member departed from the principles of the Society, and placed himself in opposition to them, he should be requested to withdraw from their body; or if seeking admission, he should be excluded. He trusted the motion would be unanimously adopted.

Professor Simpson seconded Mr. Syme's motion, and alike also defended himself from the charge of meeting homœopaths in consultation, which emanated from the same quarter. Dr. Henderson affirmed that Dr. Simpson had met him in consultation on some cases; Dr. S., therefore, called upon Dr. Henderson to ask what these cases were. It so happened that Dr. Simpson had anxiously attended Dr. Henderson's own wife, but she, with her husband's sanction, was *treated on the ordinary principles of scientific medicine*, and not *homœopathy*. In doing this no one would accuse Dr. Simpson of countenancing homœopathy. Dr. Henderson, however, mentioned two other cases,—one of uterine disease, and the other of disease of the labium. Dr. Henderson had, it is true, previously attended them, and had asked Dr. S. to take charge of them, but he did not attend them with, or for, Dr. Henderson. In one other case he certainly did meet Dr. Henderson at the bed-side, but this was a case involving an operation, and not internal treatment, but even in doing this much Professor Simpson was now convinced he acted wrongly; he had erred in going thus far. However, even if Dr. Henderson's statements had been true to a far greater extent, it only proved that hitherto the profession had been over-indulgent to him and his heresy, believing, as his friends did, that the delusion would soon subside. But, because they had been over-tolerant, it was no reason why they should continue so. It now became the duty of the Society to make their stand, feeling that every proper consideration for themselves and the noble science they cultivate, calls imperatively for a complete casting off of homœopathic practitioners, as abettors of delusions and errors. Dr. Simpson continued to draw a parallel between these impostors and the brothers in another profession—Joe Smith and the Mormons. These two heresies, the Homœopathic and the Mormonite, had in fact many points in common, and even both equally absurd. Some homœopaths profess Hahnemann to have been

despised, [Witness the ravings of the clerical witling, quoted by Dr. Cormack.—Ed. P. J.] as the Mormonites do of Joe Smith. It is true we have no standard of faith whereby to test medical opinions, but we have the standard of COMMON SENSE. Judged by this, Hahnemann's dogmas are a tissue of the strangest contradictions, and the wildest absurdities. If a grown-up man were seriously to say that two and two make five, he would not be considered sane, as he defies the dictates of common sense. When other grown-up men tell the world that they can cure this or that disease by the billionth or decillionth of a grain of a drug, they express an opinion more palpably absurd than that of him who says that two and two make five. If men would reflect what a billion or a decillion really is, they would not be so childishly credulous. There is no poison so strong that a billionth of a grain would in the least affect even a fly, much less a human being. These people tell us that division of their drugs invests them with "tremendous" power, but one of these "tremendous" billionths will not affect the frailest insect. For what is a billionth of a grain? Why, if a grain of sulphur were divided into billionths, and our first parent, Adam, had, when living, (6000 years ago,) swallowed one such billionth every second until the present time, supposing he had lived so long, he would not yet have swallowed half the grain. He must work on at the rate of sixty billionths a minute for 24,000 years to come to get through the entire grain. Yet, forsooth, these wiseacres believe that a few of these billionths will cure an attack of jaundice. Appealing to *common sense*, should not such men be requested to withdraw from scientific societies like the present. However, a billionth of a grain is a large dose; some give the tenth dilution or the decillionth of a grain. Little do they reckon what a decillion is. Here is its notation:—1,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000. Now, the world contains nine hundred millions of human beings. If all these nine hundred had lived from the commencement of the world, and each had swallowed every second of their existence a decillionth of a grain, they would not yet have finished the grain. And say the homœopaths, a few of these decillionth globules of belladonna will cure scarlet fever. One remark of Mr. Syme reminded Dr. Simpson of a curious fact in the early history of homœopathy in Edinburgh, proving on the one hand how far imagination will go, on the other hand that all homœopathic globules are alike, or rather are alike inactive. Some eight years ago Dr. Simpson received a present of a box of homœopathic medicines from an old schoolfellow, who had set up as a homœopathic druggist. During the time it was in Dr. Simpson's possession it was given as a plaything to his son, then a child. The boy amused himself by uncorking the bottles, emptying their contents into a general heap, and then refilling them promiscuously. The effect of this was a complete compounding of the globules of different kinds, by mixing them together. It soon happened that a professional brother calling at Dr. S.'s, took a fancy to the box and carried it off. Many weeks after, the new proprietor of the box met Dr. Simpson, and told him he had been trying homœopathy, with the contents of his box, and that he had accomplished wonderful cures! Dr. Simpson enjoyed the joke, and said nothing about the box until, finding his friend had got deep into the homœopathic mine, and actually published a list of cases, he at length told him of the elaborate mixture the globules had undergone. This friend is Dr. Henderson!!! In conclusion, Dr. Simpson alluded to those impostors who, pretending to be homœopathists, prescribed ordinary doses in the guise of globules, and practised either way as best suited their own pockets and the caprices of the patient. These, he argued, should be expelled from the Society.

At the conclusion of this instructive as well as important meeting, the globulists Drs. Rutherford, Russell, and James Russell, had the good sense to anticipate expulsion by resigning their seats as members of the Society.

BIRMINGHAM PATHOLOGICAL SOCIETY.

AUGUST 7TH, 1851.

*Organized Polypus of the Heart growing from the left Auricle, and hanging into the Ventricle; giving rise to a peculiar bruit, distinctly audible some yards from the Patient.**—By Dr. FLETCHER.

PHŒBE BELL, aged 34, was admitted a patient under my care, at the Birmingham General Dispensary, Oct. 15th, 1842, labouring under palpitations of the heart, difficulty of breathing, and general anasarca, from which she had suffered more or less for some years. She does not remember that she was ever strong or in perfect health. At about eight years of age she had a slight attack of rheumatism, from which time she has been considered delicate; at times she has had cough and expectoration to a considerable extent, which do not trouble her at present. She now complains of pain in the head, giddiness, and singing in the ears; great difficulty of breathing on any exertion, and a constant sense of weight and oppression at the præcordium. The bowels are open. The urine is normal in quantity, slightly acid, of the specific gravity of healthy urine, and does not coagulate by the application of heat or nitric acid. The pulse is 100 and feeble. She feels great debility, and has a pallid bluish appearance of countenance, which led me to expect there might be slight communication between the right and left sides of the heart, but on questioning her and her friends, I could not learn that there was any increase of this blueness of countenance after exertion or coughing fits.

On examination of the chest the region of the heart was found more prominent (bombé) than the corresponding portion of the right side of the chest. The movements of respiration were equal on both sides of the chest.

Percussion.—The space opposite the heart was more extensively dull than usual, and this dulness extended for about four inches square, and especially towards the left side. The upper parts of the chest sounded clearly, the inferior portions not so clearly anteriorly as normally. The action of the heart was very violent, par-

* Read before the Royal Medical and Chirurgical Society.

ticularly on the right side of the dull præcordial space above alluded to, under the costal cartilages and sternum.

Auscultation.—The sound of the heart was very loud, so much so as to be heard at a distance from the person, and on applying the stethoscope it was observed to accompany the first sound of the heart. In its character it was sharp and prolonged, a little more than the first normal sound of the heart, and on close examination it was most intense, nearly on a line with the left nipple, and about two inches to its left side, but still it was very loud over the right ventricle, and indeed all over the chest. The respiration was normal, except in those situations of the chest where there was dulness on percussion, and here it was bronchial in its character, extending a short distance around a part, at which respiratory sounds were absent. The dull space over the liver was larger than normal. All other parts of the abdomen appeared healthy on physical examination. R. Pil. Scillæ Comp., gr. viij.; Hydrarg. Chlor.; Pulv. Digit. Utrq., gr. j. Misce et divide in pilulas duas mane et nocte sumendas. A saline mixture, with diuretics, every four hours, with mild diet and diuretic drinks.

24th.—These medicines having produced no effect in reducing the anasarca, it was thought better to give the following:—R. Elaterii, gr. ½; Extr. Hyos., gr. v. Mist. fiat pil. horâ somni alternis noctibus sumend. Repeat the mixture, diet, and diuretic drinks.

26th.—The elaterium pills having produced great sickness previous to acting upon the bowels, the following combination, which has been recommended as acting without producing that distressing symptom, was resorted to:—R. Elaterii, gr. ss.; Hydrarg. Chlor.; Pip. Cayen. utrq., gr. ij.; Extr. Col. Co., gr. v. Misce et divide in pilulas duas horâ somni alternis noctibus sumendas. Repeat the mixture, mild diet, and diuretic drinks.

November 11th.—These medicines have been continued from the last date, with great benefit to the patient. The sickness from the latter combination of the elaterium has been much less distressing than from the former. The anasarca has very much diminished, as well as the palpitations of the heart, difficulty of breathing, and other disagreeable symptoms. Repeat the elaterium pills every third night.—R. Tinct. Ferri. Sequichlorid, dr. ss.; Tinct. Digitalis, m. x; Infusi. Quassiæ., oz. iss. M. ter indies sumend. Repeat the mild diet and diuretic drinks.

18th.—There is a troublesome cough and difficult expectoration. The anasarca has almost disappeared. Omit the elaterium pills. Continue the last mixture. A linctus, with hydrocyanic acid, to be taken when the cough is troublesome.

22nd.—Is going on well in every respect. Continue the medicines. The dispensary note having nearly expired, a few doses of the elaterium pills were prescribed for the patient to take occasionally. She is very much improved in all respects. The action of the heart and its sounds are very much diminished.

December 2nd.—The comfortable state described on the 22nd of November continued until two days ago, when the disagreeable symptoms from which she had previously suffered began to return, and now exists with greater intensity. She says that she has neglected to take the elaterium pills, and, in addition, has exposed herself to cold, and that she now feels extremely ill, faint, and sinking.—R. Elaterii, gr. ¼; Hydr. Chloridi.; Piperi. Cayenn., gr. ij.; Extract. Colocynth Co., gr. vj. Misce et divide in pilulas duas alternis noctibus sumendas. R. Magnesiæ Sulphatis, dr. j.; Spt. Ætheris Nitr., dr, ss.; Tinct. Scillæ., m. x.; Tinct. Digitalis, m. vj. Mist. Camphoræ, oz. iss. M. ter indies sumend. Emplast Lyttæ regioni cordis.

4th.—The remedies have been neglected, and there is increased urgency of the symptoms.

6th.—The medicines have been taken and the blister applied, which has risen well. The symptoms are slightly alleviated.

8th, 10th, and 11th.—Continues the remedies. There is no improvement since the 6th.

12th.—Evidently sinking. The sound of the heart, which has increased latterly, is now most intense; it is very distinctly heard four yards off, even when the back of the observer is turned towards the patient; and her friends say they can hear it at times in the room below. I mention these circumstances to show that the sound of the heart was detected by the sense of hearing alone, unassisted by the sight of its action, which had so increased as to move the bed-clothes. The seat of the sound, namely,—two inches on the external side of the left nipple, was very marked, and could at this time more decidedly be detected than formerly. The sound gave me the impression that it was very superficial, and that it was caused by a cartilaginous elongated adhesion of the pericardium, which was doubled up at every diastole of the heart, and elongated and put upon the stretch whilst under pressure between the heart and parietes of the chest at every systole of the organ, being somewhat under the same circumstances as good broad cloth, when tried by persons who examine its quality. She kept the semi-erect position up to this time; the pulse had varied very little at either wrist from that described at first, namely,—100, and feeble; but now no pulse could be felt at the left wrist, and the pulsations at the brachial artery were scarcely perceptible in the left arm—the only part of the body not œdematous. The pulsations in all other superficial arteries of the body perceptible, but feeble. She was evidently sinking, and required support.—R. Pulv. Ipecac. Co., gr. x., statim sumend et nocte maneque repetend. R. Spt. Ammon. Arom., m. xv.; Tinct. Lavend. Comp., m. x.; Misturæ Camphoræ, oz. j. M. tertiis horis sumend.

13th.—She died about six o'clock, P.M.

Post-mortem examination, 8 A.M, *December 15th, forty hours after death.*—Body not at all decomposed; generally œdematous, except the left arm, head, and face; and much emaciated. *Head* not examined. *Chest:* Effusion of about a pint of clear fluid into the right pleura. No adhesions of either pleura. A patch of hæmorrhagic deposit in the inferior lobe of the

right lung, about an inch and a half across, softened in the centre; another in the upper part of the inferior lobe of the right lung, not quite so large, firm throughout; otherwise both lungs perfectly healthy in their structure, but remarkably free from moisture. *Heart:* Pericardium healthy. Right auricle dilated to about three times its natural size, and so thin that in many situations the bundles of muscular structure being separated, its parietes seemed formed only of the serous coat of the pericardium; this membrane even appeared then to be put upon the stretch. The foramen ovale open sufficiently to admit the point of the little finger. The tricuspid valve healthy. The right ventricle dilated to about double its normal size; its wall firm, dense in structure, semi-cartilaginous to the feel, and thinner than normal. The semilunar valves healthy. The pulmonary artery and its branches dilated to about half as large again as their normal size. The left auricle, about half as large again as its normal size, contains a large, fleshy, tuberculated polypus, of a bright carmine colour, and gelatinous in its appearance, and at its inferior portion dotted with white fibrinous points; it measures two inches in length, and three inches in circumference, and is attached by a narrow pedicle to the septum of the auricles, about half an inch below the remaining opening of the foramen ovale; it hung down through the auriculo-ventricular aperture, so that its inferior portion was seen hanging into the ventricle, on cutting it open, surrounded by the mitral valve, which must have struck against it at every act of closing. The left ventricle a little dilated; its walls softer and more flabby than normal, and in several parts transformed into fatty matter or strumous deposit. On cutting the polypus open, a cavity was found in its centre, containing bloody serum, about the size of a small nut, surrounded by layers of fibrin, and the whole covered by a membrane continuous with the lining membrane of the auricle. *Abdomen:* The liver much congested, and about a third larger than normal. Pancreas, spleen, stomach, and intestines healthy. The kidneys appeared affected with the commencement of Bright's disease, being yellow and somewhat granular on their exterior, and the division between the cortical and tubular portions not being well defined. The rest of the urinary and genital organs healthy.

The preparation is deposited in the museum of Sydenham College, Birmingham.

EPIDEMIOLOGICAL SOCIETY.

As we cannot doubt that our readers will be anxious to be made acquainted with the proceedings of this Society during the past year, we subjoin the address of the President (Dr. B. G. Babington) on opening the present Session of the Society, which contains a brief but interesting description of the internal arrangements and actual operations of the various special committees, as well as a list of the subjects of the different papers which have been read at the monthly meetings. We wish to direct particular attention to the inquiries issued by the Committee on Small-Pox and Vaccination, and to express a hope that the members of the Provincial Association will *all* contribute some information on so important a subject. It will also be observed that Dr. Babington alludes to the interest which Sir Charles Hastings expressed with regard to the Epidemiological Society at the meeting at Brighton, "calling upon the members of the Association to give it their warmest support."

ADDRESS.

"Gentlemen,—When I had the honour of addressing you from this chair, at the first ordinary meeting of the Epidemiological Society, in December last, I spoke of the origin of the Society, and of its progress up to that period.

"Part of the duty I have to perform on this the commencement of our second session, and, happily, under the same time-honoured and, to us, hospitable roof, is, gentlemen, to give you a brief account of what the Society has done since it held its first ordinary meeting here. A statement of this kind will not be without its utility, in showing to ourselves and others, that the tide of our undertaking is flowing on continuously and prosperously, as measured by the interesting matter brought forward at our monthly meetings, and, moreover, that we have an undercurrent, at least equally strong, in the more quiet but no less efficient working of our various Committees.

"On the 2nd of December, 1850, after I had concluded my address, a paper, by Dr. Bryson, 'On the Infectious Origin and Propagation of Cholera,' was in part read by that gentleman.

"At the second ordinary meeting, (January 6, 1851,) the reading of Dr. Bryson's paper was concluded.

"At the third ordinary meeting, (February 3,) a paper 'On the Origin and Progress of Cholera in Guernsey,' by Dr. Elliott Hoskins, was read by Dr. Gull.

"At the fourth meeting, (in March,) Dr. M'William read a paper 'On the Recent Yellow Fever Epidemy in Brazil.'

"At the fifth meeting, (April 7,) Mr. R. H. Cooke was present to read a paper 'On the Epidemic Mental Diseases of Children;' but the meeting having resolved that the discussion on yellow fever should be continued during that evening, Mr. Cooke kindly consented to postpone the reading of his paper until the meeting in June.

"At the sixth meeting of the Society, (May 5,) the discussion on 'yellow fever' was resumed, and, having continued longer than was anticipated, Dr. Snow, who began a paper 'On the Mode of Propagation of Cholera,' was obliged to defer its conclusion.

"At the seventh meeting, (June 3,) Mr. R. H. Cooke read his paper 'On the Epidemic Mental Diseases of Children,' founded on Hecker's two pamphlets,—the one entitled, 'Children's Pilgrimages,' and the other 'Sympathy;' after which Dr. Snow finished his paper on Cholera.

"At the eighth meeting, (July 7,) Mr. Hunt read a paper 'On the Uses and Limits of Statistical Science as applied to the Study of Epidemic Diseases.'

"At the ninth and last meeting of the Society, (Aug. 4,) a paper 'On the Nature of Epidemics,' by Mr. Grove, was read by Dr. M'William.

"The reading of each of these papers was followed by a discussion; and reports and abstracts of all the papers read at the Society's meetings have appeared in the London and Provincial Medical Journals.

"The paper by Dr. Bryson, 'On Cholera,' and that by Dr. M'William 'On Yellow Fever,' have each, by the permission of the Council, been published in the form of a pamphlet; and Dr. Bryson's paper having been collated from official documents, it was necessary for him to obtain the sanction of the Lords of the Admiralty, which I understand was willingly granted, prior to its publication.

"Having thus presented you with a brief outline of the proceedings of the Society at the ordinary meetings, I feel bound to mention, that, on each occasion, the members and visitors gave ample testimony of their sense of the value of the papers read before the Society. Gentlemen, it is to me a source of much regret—for our utility is considerably lessened by the circumstance—that the present state of its finances will not permit the Society to publish these valuable contributions. Let us hope, that the time is not far distant when, by a more general interest manifested in our labours, and a corresponding increase in our resources; we shall be enabled to do so.

"I may however state, that in the meantime, although there is a law of the Society to the effect, that all Papers, after being read, shall become its property, the Council will not refuse to permit their authors to publish them either in the medical journals, or in a separate form.

"While on this subject, I may add, that a resolution of Council has been passed, that the discussion on any paper shall not be prolonged beyond the second night, as a contrary practice was found to interfere with the business of the Society.

"As there may be present some of our members who have not seen the medical journals in which, from time to time, the working of the Society has been noticed, I may state, that the various committees formed for special purposes have been for some time steadily engaged in the performance of the duties they have respectively undertaken; and, with your permission, I will therefore say a few words respecting their progress

"*The Committee on Small-pox and Vaccination* have issued nearly one thousand printed forms of queries to hospitals and dispensaries, to union medical officers, and to other members of the Profession in London and in the country. Besides these, about thirty copies have been transmitted through the Hon. the Board of Directors of the East India Company, to medical men officially employed in the three presidencies of India. There have been already received by the Secretary of the Committee 254 replies to the queries—a number considered sufficient to enable the Committee to proceed with their analysis without waiting for others that may come in. The Committee are however of opinion, that at least 800 more forms might be very advantageously distributed, so soon as there are funds to cover the necessary expense.

"*The Common Lodging-houses' Committee*, for the purpose of investigating the condition of common lodging-houses, as influencing the propagation and spread of epidemic diseases, have distributed 250 forms of queries, to which a sufficient number of replies has been received to enable them to draw out a Report which has already been submitted to the Council.

"The *Hospitals Committee*, or Commitee to inquire into the epidemic diseases originating and prevailing in public hospitals, have held several meetings at the house of the Chairman, Dr. Addison, and have drawn up a tabular form of queries, which they purpose sending to all the British hospitals. For this purpose they have applied to the Council for a grant of money.

"The last Committee that was formed is that styled the *Epizootic Committee*, its object being the investigation of those diseases which are found to prevail extensively among the lower, and more especially the domesticated animals. The working of this Committee has been undertaken by Professor Symonds, of the Royal Veterinary College, who will be aided in his labours by gentlemen of the veterinary profession in London and in the provinces. Already several veterinary surgeons in the provinces have been announced as Corresponding Members of the Epidemiological Society. In compliance with a desire expressed by Professor Symonds, that some members of the medical profession should unite with the veterinary members in carrying out the objects of the Epizootic Committee, several members of the Council have already given in their names to be placed upon that Committee.

"As connected with these Committees, more especially with the Common Lodging-houses' Committee, I must not forget a debt of gratitude we owe to some of the laity, members as well as non-members of the Society. The gentlemen of the City Mission readily tendered their valuable assistance to the Common Lodging-houses' Committee, and greatly facilitated their inquiries regarding the influence which the receptacles of the lowest and most depraved portions of society exerted in originating and spreading epidemic disease.

"Valuable information, I am thankful to acknowledge, has also been rendered to the Common Lodging-houses' Committee by Mr. Charles Cochrane, a lay member of the Society, distinguished, as we all know, for his philanthropic exertions in the cause of sanitary improvement.

"To the medical journals the gratitude of the Society is eminently due, for the facility they have afforded to the Honorary Secretaries and Secretaries of Committees, in giving notice of meetings, publishing reports, and impressing the profession with the necessity of sending in answers to the queries issued by the respective Committees.

"The Editor of the *Veterinarian*, in his journal of

September last, has dedicated a leading article to the Epidemiological Society.

"Some important articles have also appeared in the *Assurance Magazine*, urging in strong terms the cause of the Society, and the benefits that must accrue to Assurance Societies by a due appreciation of those sanitary principles and laws which may be directed towards the mitigation, not only of sweeping epidemics, such as cholera and influenza, but also of other diseases, which are silently, constantly, and even more fatally operating to the destruction of human life.

"The publicity given to the objects of the Epidemiological Society in the *Assurance Magazine* has procured for us a favourable notice in a German journal, the *Rundschau der Versicherungen*, Edited by Herr E. A. Musius, of Leipsic.

"To the General Board of Health and to the Poor-law Board, the best thanks of the Society are due, for the permission given by these bodies to the members of the Small-pox Committee to have access to documents in their possession regarding the subject of small-pox; and to the Registrar-General we are greatly beholden for the facilities he has afforded us by the distribution of our papers among his subordinate officers.

"For the information of those members of the laity who seldom if ever see the medical journals, I have much pleasure in stating that, at the Nineteenth Anniversary meeting of the Provincial Medical and Surgical Association, held at Brighton in August last, Sir Charles Hastings, the founder of the Association, spoke highly of the objects and claims of the Epidemiological Society, and called upon the members of the Association to give it their warm support.

"The field of inquiry open to this Society is not limited to Great Britain alone, for it comprehends all parts of Europe, and extends even to India (the cradle, so to speak, of epidemic diseases), and to every portion of the habitable globe.

"Impressed with this view, and feeling the necessity of establishing communications with the various countries of Europe, and with foreign as well as with our own Colonial possessions, a Committee has for some time had under contemplation the subject of the appointment of Foreign Secretaries. Some progress has already been made in their arrangements, and the list of Secretaries will doubtless soon be complete.

"From Bengal two important letters have been addressed to the President and the Secretary of the Society, on the subject of small-pox and vaccination in India, by Mr. Bedford, a medical officer in the Company's service.

"A pamphlet by the same gentleman has more recently reached this country, in which the author submits some very important suggestions for the extension and perfection of vaccination, simultaneously with the systematic study of epidemic and endemic disease in India. I cannot, gentlemen, resist the temptation to read the following passage from this publication:—'Epidemic diffusion' is the most important medical question of the day, and can only be studied through systematic and parallel observations, conducted by a number of intelligent men working under one head. India, from its climatic peculiarities, and the nature of its 'services,' offers, I hesitate not to affirm, the most magnificent field in the world for carrying out such a series of connected observations as may tend to elucidate the laws of the most terrible diseases which 'flesh is heir to;' and it will redound to her eternal honour to be in advance in such inquiries. So pressing has the question now become in Europe, that an epidemiological society has been formed, for the special purpose of collecting information in regard to this class of disease.'

"Having thus, gentlemen, given you a hasty, and, I fear, but an imperfect sketch of the past proceedings of the Society, I feel it my duty, before concluding, to say a few words as to the future.

"I have already alluded to our working Committees, who are, so far as their means will admit, actively and zealously engaged in the prosecution of their respective inquiries. Able and hearty co-operation is offered to the Society, both at home and from abroad; and, for so young an institution, it may be truly said, that the Epidemiological Society has excited an unwonted degree of interest and sympathy among the lay as well as the professional community. But, like other societies not yet emerged from the struggles of the infant state, our finances are not in a very flourishing condition.

"The heavy outlay consequent upon the earlier meetings, and upon other means of giving due publicity to the existence of the Society; the expense of printing and distributing the rules and objects of the Society; of the printing and postage of the queries issued by the various Committees, with other unavoidable sources of expenditure, have, (notwithstanding the kind and courteous liberality of the Council of the Royal Medical and Chirurgical Society, in granting us the gratuitous use of their rooms during the past and present session,) exhausted the amount received in donations and subscriptions during the past year.

"But there is no reason to despair. The active and enlightened benevolence of this country is not likely to turn aside from a society whose labours, devoted as they are directly to the physical welfare of mankind, cannot be successfully prosecuted without influencing likewise their moral condition. We therefore rely much upon public feeling and individual exertion, to induce others to join our ranks, and to aid us by pecuniary grants.

"Already have some public bodies given us substantial proofs of the interest they take in our cause; and when, by the publication of one or more of our Committee reports, the attention of the Government and of the Honourable East India Company shall have been more immediately called to the importance of the objects and aims of the Society, we may reasonably expect some assistance form those quarters, in furtherance of the good work.

"For ourselves we have only to do our duty, by endeavouring, as far as lies in our power, to accomplish the noble ends the Society has in view."

General Retrospect.

ANATOMY AND PHYSIOLOGY.

On the Effect of Chloroform on Muscular Fibre.—By W. F. Barlow, Esq., M.R.C.S.,

Mr. Barlow has performed a series of experiments, which seem to show that chloroform rapidly exhausts muscular irritability, and in common with other agents inducing the same effects, conduces to the rapid stiffening called rigor mortis. He observes:—"It has been shown by Nysten, in his ingenious researches, that a long time intervenes, as a general rule, between dissolution and this peculiar rigidity, during which time the muscles remain irritable; and that the rigor does not approach until the muscular irritability is either completely or nearly extinguished. This, is of course, a main fact. All kinds of muscular action prove the irritability of muscles, except rigor mortis; this, on the contrary, is a form of contraction which prevails not until muscular irritability is lost. After *excessive voluntary* action, such as that of the hunted animal, which though exhausted to the utmost, still runs for life, and forces to contraction, muscles become almost too languid to respond effectually to any stimulus, however violent, rigor mortis has been commonly noted to ensue with unusual rapidity. As Nysten says, "c'est parceque l'action vitale du lièvre que le chasseur a forcé est, pour ainsi dire, epuisée par une fatigue excessive, que cet animal se roidit en mourant." So, too, *extreme involuntary* muscular contraction has been known to lead to the swiftest possible death-rigor. And it is very probable that the exhaustion of muscular irritability after death by galvanism would be found to hasten the phenomenon."

The experiments were performed on frogs and birds, decapitated and skinned, and afterwards suspended in a bottle containing chloroform. In a medico-legal point of view they are important, as if the same effects are produced on the human subject, a person poisoned with chloroform might, from the muscular rigidity be thought to have been dead some time, when in reality the reverse is the case.—*Medical Gazette*, October 24, 1851.

PRACTICAL MEDICINE AND PATHOLOGY.

The Skin as an Indication of the State of Health.—By Mr. Hunt.

[How true are the indications of the condition of the horse, which his skin affords, is well known to all who are familiar with the noblest of animals; but it may be a matter of doubt how far in the human subject we can trust to the same characteristics. Mr. Hunt has, however, turned his attention to the subject in a paper of which the following is an abstract:—]

The author commenced by observing, that the subject naturally divided itself into two parts—viz., 1. The indications presented by the healthy skin. 2. Those presented by the skin in a state of disease. Having alluded cursorily to the former, by pointing out some of the indications presented by changes in the condition of the skin as to smoothness or roughness, moisture or dryness, temperature and colour, Mr. Hunt proceeded to discuss the constitutional indications presented by the diseased skin, confining his remarks to a single topic—namely, the rapidity or slowness of development which characterized respectively the various orders of cutaneous diseases, as arranged by Dr. Willan. To explain this point more fully and forcibly, he placed the first seven orders of Willan in a new rotation, selecting two diseases as types of each order, by way of illustrating the subject, as follows:—

Orders.	*Types.*
1. Exanthemata	Urticaria. Erythema.
2. Bullæ	Erysipelas. Pompholyx.
3. Vesiculæ	Eczema. Herpes.
4. Pustulæ	Ecthyma. Impetigo.
5. Papulæ	Lichen. Prurigo.
6. Squamæ	Lepra. Pityriasis.
7. Tubercula	Acne. Lupus.

The first three of these orders, viz., *Exanthemata*, *Bullæ*, and *Vesiculæ*, were described as comprising, for the most part, diseases of rapid evolution or development; the last three, viz., *Papulæ*, *Squamæ*, and *Tubercula*, containing diseases of slow development; the order *Pustulæ* taking an intermediate position in this respect. On this basis the author proposed to establish a theory, for the support of which he produced many curious facts relating to the artificial production of the various forms of skin disease, as well as facts connected with the development of spontaneous eruptions. The theory consisted in regarding eruptions as defensive efforts of nature, tending either to prevent the absorption of poisons, or to eliminate them when absorbed: those poisons or injurious agents which are most actively mischievous being most rapidly eliminated or repelled, exciting the blush (*Exanthema*), the blister (*Bulla*), or the vesicle (*Vesicula*); those which are less rapidly destructive, exerting a slow and feeble effort at elimination, as observable in the pimple, (*Papula*), the scale (*Squama*), or the tubercle (*Tuberculum*); while those poisons which are of intermediate intensity of action originate the pustular form of eruption. Taking seven diseases as so many types of these orders respectively, the author observed that their average duration, when unchecked by treatment, was strikingly illustrative of the truth of this theory of development. Thus, urticaria continues usually a few hours, erysipelas a few days, herpes twice as long, ecthyma a few weeks, lichen as many months, lepra as many years, and lupus for the whole life, each eruption showing the relative degree of intolerance of the poison manifested by the system, and thus becoming a signal of danger. Mr. Hunt contended, that if this theory should prove to be true, it might throw some light on the prognosis, the pathology, and the therapeutics of cutaneous disease,—assisting the prognosis by determining how long the disease might be expected to last; the pathology, by pointing out the hidden cause of the disease, and its relative activity or destructive power; the therapeutics,

by suggesting long perseverance in one judicious plan of treatment in the diseases at the bottom of the list, and by indicating some error of treatment when the case of those at the opposite end of the chain does not proceed at a rate corresponding with their natural rapidity of development. These positions were illustrated by allusions to the action of external agents in the production of various eruptions, as well as internal sources of cutaneous disease; and among other important facts it was stated, while the diseases included in the first four or five orders were producible by external agents with a readiness diminishing from above downwards, it was impossible to establish the eruptions at the bottom of the list, (lupus, acne, lepra, psoriasis, &c.,) by any external application whatever. The author concluded by remarking, that amidst the general obscurity in which cutaneous pathology was involved, it was sometimes a relief to follow a faint and feeble light, in the hope of its leading to further discoveries, and that this was the highest character he claimed for the observations to which the fellows had so kindly listened on the present occasion.—Reported in *Lancet* November 1, 1851.

SURGERY.

Treatment of Diseased Joints on Mr. Gay's Plan.

Mr. Gay has recently advocated the plan of making free incisions into diseased joints, for the purpose of fairly evacuating the debris of cartilage, pus, &c., which are the chief impediments to anchylosis. This plan is not, however, altogether original with Mr. Gay: we have a recollection of its being mentioned in the French journals many months back, as being practised in the French hospitals, by M. Lenoir. A good case in point is recorded in the *Medical Gazette*, in which success was obtained under the most unpromising circumstances.

On Fœtid Exhalation from the Feet.—By Sir H. Marsh, Bart.

This writer, alluding to the above distressing affliction, mentions the case of a gentleman who was compelled to lead the life of a hermit, excluded from society by the exceedingly offensive smell which issued from the spaces between the toes. It was disagreeably perceptible the moment he entered a room; no amount of cleanliness or repeated ablutions dissipated the fœtid odour. Deodorizing applications of various kinds had been tried, and with only slight and temporary benefit. The treatment from which, as long as he remained under the writer's observation, he appeared to derive advantage, was a daily tepid bath, a diet exclusively vegetable and farinaceous, and the frequent application between the toes of the following ointment:—Mercurial ointment, one ounce; creasote, one drachm; muriate of morphine, half a drachm. Sir H. Marsh states that he returned to thank him for the good he had derived from the treatment; but whether the cure was perfect and permanent, he cannot affirm.—*Dublin Medical Press*, Nov. 12th, 1851.

Correspondence.

THE ROYAL COLLEGE OF SURGEONS AND HOMŒOPATHY.

Correspondence between Dr. J. C. Hall, of Sheffield, and the Council.—Protection of Homœopathic Quacks by the Council.

To the Editor of the Provincial Medical and Surgical Journal.

Dr. J. C. Hall presents his compliments to the Editor, and requests the publication of the enclosed correspondence with the Council of the Royal College of Surgeons of England, in the next number of the *Journal*.

Surrey Street, Sheffield, Dec. 1st, 1851.

Royal College of Surgeons of England,
Nov. 28, 1851.

Sir,—I am desired to transmit to you, in reply to your letters on the subject of homœopathy, a copy of the following resolution of the Council of this College, on the 26th instant, viz:—

"That the Council have attentively and repeatedly considered the various communications which they have received on the subject of homœopathy, and after mature deliberation, have resolved that it is not expedient for this College to interfere in the matter."

I am, Sir,
Your most obedient Servant,
E. Belfour, Secretary.

To Dr. John Charles Hall, &c., &c.,

Surrey Street, Sheffield,
Nov. 29th, 1851.

Gentlemen,—I am truly glad you have at length broken the silence you have so long kept, and that by the answer you have directed your Secretary, Mr. Belfour, to forward in reply to my repeated communications, the profession will be made aware of the course you propose to adopt with regard to those members who, by practising homœopathy, have rendered themselves in the words of your bye-laws, "disgraceful to the College." You have not ventured to say that our demands were either unjust or unreasonable, nor do you say it would be right to follow the noble example set you by the Royal College of Physicians, and the Royal College of Surgeons of Edinburgh; but you say that "*it is not* expedient *for this College to interfere in the matter.*" "*Not expedient*" for you, in obedience to the oath you have taken, to maintain the honour and dignity of the College;—"*not expedient*" for you to protect and defend every member who may be disturbed in the exercise and enjoyment of the rights, privileges, exemptions, and immunities he has acquired (bye-laws, p. 14) "*not expedient*" to put into force those powers; which you most unquestionably possess, and which you do not attempt to deny, for excluding from the lists of members those who are endangering the reputation of the College by practising homœopathy, or any other

gross or open quackery; and, bear in mind, I have only asked that they should not be permitted to practise homœopathy, as members of our College, having no wish in any other way to interfere with them.

Gentlemen, the result of your mature deliberation I have, by this night's post, transmitted to the Editor of the *Journal* of the Provincial Medical and Surgical Association, to the Editor of the *Lancet*, and the Editor of the *Medical Gazette*; so in less than a week what is considered as "*expedient*" by you with regard to quackery will be known from one end of the kingdom to the other; and I shall have, at any rate, the satisfaction of knowing that to the best of my ability I have endeavoured to maintain the honour and dignity of our College; nor is any apology necessary for the course I have taken.

"Licet omnibus, licet etiam mihi, dignitatem, *Artis Medicæ* tueri."

With my brethren in the profession I now leave this important question; and it will be for them to consider whether it be "*expedient*" (I thank you, Gentlemen, for teaching me that word) to permit additional powers to be given, under the proposed *new Charter*, to a body of men who are so unmindful of the honour and dignity of the College as to consider rather what is "*expedient*" than to do what is just. Surely the shade of Machaon* must, ere this, have blushed for "*expediency*" such as yours; nor could the talent of a Podalirius cure a "falling sickness" such as the one with which you are evidently affected. And, oh! with pain and deep humiliation I feel that the doings of a majority of your body (for I am certain there are those great and good men amongst you who could never have voted for such a resolution) are, indeed, contrary to the motto of our College,

"Quæ prosunt omnibus artes."

And now, gentlemen, for the present, I take leave of you, appealing with all confidence, from the course you have considered it "expedient" to take, "*after mature deliberation*," to the profession generally. Let the profession judge between us! For my own part I do not fear the result of that verdict, which, happily for the cause of truth and justice, the Council of the Royal College of Surgeons of England cannot possibly escape.

I have the honour to be, gentlemen,

Your very obedient servant,

JOHN CHARLES HALL, M.D.,

Fellow of the Royal College of Physicians, Edinburgh, Lecturer on Anatomy, Pathology, and Physiology, at the Sheffield Medical Institution.

To the Council of the Royal College of Surgeons of England, &c., &c., &c., London.

* See the College Seal.

MR. PERCEVAL'S ATTACK ON PRIVATE LUNATIC ASYLUMS.

To the Editor of the Provincial Medical and Surgical Journal.

SIR,—I cannot but regret exceedingly that such a letter as Mr. Perceval's, on the "Treatment of the Insane," should have been suffered to appear in the last number of the *Provincial Medical and Surgical Journal*. The invidious and cruel charges that he makes at the close of that letter are a direct attack, (unjust as, I believe, untrue,) upon a body of gentlemen, members of the medical profession, and Associates in a Society of honourable men.

The *Journal* is made the vehicle of aspersion upon such by a non-medical writer; one who, by his sweeping condemnation of private character, on the self-erected plea of public good, looks evidently with a jaundiced eye on the subject on which he writes, and exhibits anything but a clear proof of his own possession of a well regulated mind. Why are a body of men actively in pursuit of arduous and delicate duties, which are necessarily in themselves a ceaseless stretch on their own minds, to be attacked through the pages of their own journal, by the Secretary of any Society; more especially of a Soicety calling itself by an exclusive cognomen—the Alleged Lunatic's Friend Society, but believed, as it is, by many practical men, to be just the reverse? It is the foolish fashion of this Society never to give credit for honesty of intention to any one who has the care of the insane. But I ask you, Sir, just to revert in recollection to the names of many of our Associate members (names neither self laudatory or puffed into notoriety, but amongst the honourable, for character and standing), who have the private charge of insane patients; and to imagine, if you can, such flagrant violations of honesty being substantiated, or such temptations yielded to, as Mr. Perceval's letter implies against them. He says, "In the existence of private lunatic establishments is the temptation afforded to human weakness to receive without much scruple, or to detain when no longer necessary to do so, persons, as patients, whose residence is profitable to the proprietor, or who may damage his interests by making an unfavourable report of his establishment, and the temptation to *stint* the patients in *medicine, food, accommodation, exercise, amusement*, or *attendance*, to make a greater profit out of the allowance for their maintenance." Are we to credit, on the authority of this letter, published in our own journal, that "these objections can hardly be effectually removed, because so much duplicity and plausibility are exercised in these matters?"

In putting these questions I would add, that I have no interest whatever in any private asylum—indeed my interests are all the other way; but I have known, throughout a lengthened life amongst the insane, so many valued friends who have been entrusted with their care, that I would not suffer such statements to pass without one (if it be *but* one) solitary protest against them.

I beg to remain, Sir, with much respect,

Your very obedient faithful servant,

AN ASSOCIATE MEMBER OF COUNCIL.

November 28, 1851.

[We inserted Mr. Perceval's letter because we think it better that free discussion should be allowed in all cases where personality is avoided. The subject is one which, just now especially, admits of two points of view; though we think Mr. Perceval has overstepped the bounds of common-sense in his sweeping charges against all private aslylums.—ED. J.]

QUEEN'S COLLEGE DEBATING SOCIETY, BIRMINGHAM.

To the Editor of the Provincial Medical and Surgical Journal.

Sir,—A passage in Mr. Harrison's address before the "Bristol Royal Infirmary Medical Society," which appeared in your *Journal* of the 12th ult., has just been pointed out to me, and since I am satisfied that the claim made by that gentleman for Bristol, respecting the priority of establishment in the provincial schools of a society, for the discussion of medical subjects, is entirely unfounded, I feel it my bounden duty to give an unqualified contradiction to that statement.

If my recollection serves me, the society formed in connection with the Bristol Royal Infirmary, was opened in January last, by an introductory address from Dr. Wallis. Now, I have only to refer to the records of the Society established here, to bring proof that several meetings had been held, and some important subjects discussed, before the issue of the circular, which was a proposal to originate a society, somewhat similar in its objects to our own, at the Bristol Infirmary; and had not that circular been shown me at the time by a friend, it is highly probable that Mr. Harrison's statement would have remained without contradiction, at least so far as I am concerned. To show that the claim which has been made cannot be a just one, I have only to make the assertion that a Debating Society was established at this College more than ten years ago, but its discussions, from some cause or other, were not continued.

Sufficient has I conceive been said, to prove that to Queen's College, Birmingham, belongs the honour, if not of having first established a Debating Society, in which subjects of medical and general interest should be discussed, at least of having a prior claim to it, than that which has been put forth by Mr. Harrison for the Infirmary at Bristol.

Requesting insertion of this note in the next number of your valuable periodical,

Believe me to be, Sir,

Your most obedient servant,

WILLIAM WEBB,

President of the Queen's College Debating Society.

Queen's College, Birmingham,
December 3, 1851.

Medical Intelligence.

EPIDEMIOLOGICAL SOCIETY.

At the next meeting of the Society, to be held on Monday, December 1, 1851, at the house of the Royal Medical and Chirurgical Society, 53, Berners Street, two papers will be read, one "On Cholera in Jamaica," by Dr. Gavin Milroy; the other "On a Mode of Treatment of Cholera," by W. J. Cox, Esq.

APPOINTMENTS.

Mr. Waken has been appointed Surgeon to the Queen's Prison, in the room of Dr. Robert Little Hooper, deceased.

ROYAL MUNIFICENCE.

Her Majesty has been pleased to grant, out of her privy purse, an annuity of £50 to the widow, now in her seventy-first year, of the late Dr. Robert D. Davis, late of 17, Russell Place, Fitzroy Square, the Physician-Accoucheur in attendance at the birth of her present Majesty. Dr. Davis's decease, it will be remembered, took place in 1841.

ROYAL COLLEGE OF SURGEONS.

John F. South, Esq., President of the Royal College of Surgeons, and Cæsar Hawkins, Esq., Vice-President of the College, had an interview with Sir George Grey, on Friday last, at the Home Office.

SOCIETY OF APOTHECARIES.

Gentlemen admitted members on Thursday, Nov. 20th, 1851:—Thomas George Fitzgerald, Army; Charles Christopher Hewitson, Stanhope; Charles James Morris, Hampton-wick; Charles Joseph White, Portsmouth.

Gentlemen admitted members on Thursday, Nov. 27th, 1851:—Frederick William Hart Bayles, Stiffkey, Norfolk; Thomas Hales, Ford Green, Staffordshire; Alfred Wall, Stratford-on-Avon.

OBITUARY.

November 5th, Joseph Thomas, Esq., surgeon, Wrexham. The deceased was a member of the North Wales Branch of the Provincial Medical and Surgical Association.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen will observe that the Annual Subscriptions become due on the First of January, those who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association, Worcester.

It is also particularly requested that all post-office orders should be sent either to the Treasurer or Secretary, who alone have the power of giving receipts.

JAMES P. SHEPPARD, Secretary.

Worcester, September, 1851.

Erratum.—In Dr. Nelson's lecture in last number, November 26th, at page 649, second column, and sixth line from the bottom, for "inefficiency" read *efficiency*.—D. N.

TO CORRESPONDENTS.

Communications have been received from A Member of the Provincial Association, E. B., Mr. Duke, Dr. Oke, Dr. Fraser, Dr. Robertson, Observator, Dr. Barclay, Mr. Gall, Mr. Webb, Mr. Reid, and Mr. Jones.

It is requested that all letters and communications connected with the *Editorial department* be sent to J. H. Walsh, Esq., Foregate Street, Worcester. Parcels and books for review may be addressed to the care of Mr. Churchill, Princes Street, Soho. But all communications respecting the routine business of the Association should be forwarded to James P. Sheppard, Esq., the Secretary of the Association.

NOTES
ON THE
TREATMENT OF CURABLE DISEASES.

By W. S. OKE, M.D.,

Extra-Licentiate of the Royal College of Physicians, Physician to the Royal South Hants Infirmary, &c.

It is a remarkable feature of the present era of medicine in this country that a large number of medical practitioners—men who have been regularly educated in the established schools of physic;—men who, by virtue of the knowledge therein acquired, have obtained from authorised tribunals testimonials of their fitness to practise;—men who are, therefore, morally pledged to uphold the character of their diplomas,—have unscrupulously forsaken the ranks of their profession to practise certain strange methods of cure which have sprung up in Germany under their respective founders Mesmer, Priessnitz, and Hahnemann.

It might be asked,—What is the cause of such delinquency? Is it to be found in any obvious superiority of the systems they have embraced, or in a general declension of the doctrines taught in the medical schools? Not in the former, for neither mesmerism, nor hydropathy, nor homœopathy is possessed of any principles which are entitled to the slightest respect; indeed some of their extravagancies, such as clairvoyance, globulism, &c., are utterly ridiculous and contemptible. It cannot be occasioned by the latter, because there probably never was a period when the practice of medicine was carried out with more science, zeal, and success.

Whatever be the motive for such a line of conduct, it is deeply to be regretted that so many respectable men, whose talents might have shed a lustre upon the paths of their profession, should tarnish their reputation by practising quackeries, some of which they themselves must be conscious are not founded upon truth.

On the other hand, the character of medicine has nothing to fear from these alloys. It can neither be amalgamated with nor disparaged by them. There is no agreement betwixt light and darkness, and no union between truth and quackery; and whilst these novel empiricisms will not outlive the age that has given them birth, and will become the laughing-stock of the future, the legitimate practice of medicine will hold on its honourable cause, dispensing its varied benefits to the sick, and carrying with it the respect and confidence of the civilized world.

But these observations are not intended to attribute the superiority of practical medicine over empiricism to the possession of mathematical laws. It is at once admitted that it is not a science in the highest sense of the term—that is, possessing certainties grounded on demonstration. Nevertheless it is a practical science, and has the power of conferring a large amount of benefit upon mankind; for although there are grievous diseases over which it has no curative control, and recoveries which cannot be called *cures*, there are some diseases which, humanly speaking, cannot be cured without it, many cures which are greatly promoted by it, and scarce a disease which cannot be in some measure alleviated by it. This has been achieved by experiment and observation, aided by the splendid discoveries in chemistry; and by this method only can it go forward in the hope of triumphing over some of those diseases which yet remain incurable. It is this which constitutes what is commonly called experience—so valuable to the medical man, and so valued by the public at large; for surely it will be allowed that the less demonstrative certainties we possess to produce therapeutic results the more experience we stand in need of to guide us in the fulfilment of curative indications. Every candid practitioner will, I believe, acknowledge this, when, in the discharge of his arduous duties, he is combating a disease which endangers the life of his patient and fills his own mind with painful anxiety.

Upon this ground I shall venture, from time to time, as opportunity may permit, to supply our *Journal* with some of the results of my own experience, in the hope of upholding, however feebly, the character of practical medicine—a character which it has fairly won in the paths of zeal, observation, and candour, and which it will never lose till it departs from them.

It is not presumed that the means which I have found successful will always prove to be so in aspects of disease apparently similar; because it too frequently happens that diseases which *appear* to be of a similar character will turn out to be in reality very different, and require a different mode of treatment; nevertheless, when a given treatment has been found to be successful in a certain assemblage of symptoms, it may be recorded as one method of cure.

Defective Power of the Lower Extremities in the Second Year of Childhood.

This is a case which often comes under my observation, and which, I believe, has been overlooked. The child, instead of being able to stand at the usual time, is found to be unable to bear the weight of the body on its lower limbs, the muscles of which are in some degree wasted and flabby. Upon examining the spinal column in the sitting posture, a slight posterior curve of the inferior dorsal vertebræ will be discovered, which will at once indicate the cause of the want of power.

The following mode of treatment I have commonly found successful:—A small blister about an inch and a half long by half an inch broad is to be applied on each side of the curve once in a fortnight; the system is to be supported by prescription No. 1, and the bowels gently corrected once a week by No. 2.

1.—R. Vini Ferri, m. xx.
Detur hœc dosis infanti bis quotidie ex aquæ pauxillo.

2.—R. Hydrargyri cum Cretâ, gr. ij.
Rhei Radicis Pulv., gr. iv.
Pulveris Cinnamoni Comp., gr. j.
Misce fiat dosis semel in septimanis sumenda.

The child is never to be carried *upright*; and as it will be of great importance to take it into the open air in fine weather, it may be laid upon a small mattress in a concave wicker tray, which will be found light and convenient for the purpose. When left to itself it should be laid on a mattress either upon the floor or upon a bedstead; and this treatment should be continued until it regains sufficient power to attain the upright posture.

Case.—A lady, on discovering that the lower limbs of her child, although fifteen months old and of healthy appearance, always gave way under the weight of the trunk, brought it to me to ascertain the cause. On examining the spinal column I found a slight posterior curve of the spinous processes of the inferior dorsal and upper lumbar vertebræ. A small blister was ordered to be applied on each side of the curve, half a fluidrachm of the Vinum Ferri to be given twice a day, and strict directions were given that no further attempt should be made to induce the child to stand upon its feet for some time to come, and that it should be carried into the air in a recumbent position in a wicker tray. The result was, that in a few months it completely recovered the use of its legs, and went on well. Were it necessary, I could adduce very many cases of the same kind to prove the success of this mode of treatment.

The strength should be supported, if the child has been weaned, by equal parts of milk and barley gruel.

Convulsions in Children.

Convulsions in children are most commonly brought on by reflex action, from some cause external to the brain, such as teething, crudities in the alimentary canal, &c.; but they are sometimes the result of a congested state of the cerebral vessels, and, therefore, an early and correct diagnosis is of the highest importance. If they are occasioned by the former, there may be no antecedent cerebral symptoms to warn us of their approach; they will, probably, soon cease. And, moreover, some advancing teeth, or improper food, will perhaps at once manifest the exciting cause, and the method of cure. If from the latter, they will be preceded by symptoms of cerebral congestion, such as inaction of the bowels, a drowsy aspect, pain of the head, (if the child be old enough to express it, if not, the hands will be frequently carried there,) immobility of one or both pupils, involuntary movements of the eye-balls, and grinding of the teeth. Convulsions following these symptoms do not subside like those which are produced merely by the irritation of teething, or of crudities in the stomach; and unless they are combated by a prompt and decided treatment, will continue till the brain becomes oppressed by serous infiltration, which is almost certain to end in insensibility, profuse sweats, intermittent breathing, and death. In this case we ought not to wait for the bleeding of leeches, but should immediately open the external jugular vein, and take away as much blood as the circumstances may require. It may be done in the following simple manner:—Having carried a ligature of tape, or of anything at hand, around the side of the neck about to be punctured, and under the opposite axilla, sufficiently tight to make the vein rise, the integuments and platysma myoides muscle are to be freely divided by the edge of the lancet, by which the vein will be brought into view, and easily punctured. The best receiver will be a common saucer, the lip of which is to be made to press upon the vein below the orifice.

I have frequently seen the greatest benefit from this practice, which I fear is too much neglected in the present day. The scalp should now be shaved, and covered with a bladder half filled with pounded ice, or snow, if at hand. The head and shoulders are to be raised, and supported in position by a hard pillow. No. 1 is to be given immediately, and No. 2 in two hours afterwards.

1.—R. Hydrarg. Chlor.,
Scam. Pulv. utrq., gr. iij.
Misce. Detur statim in simplice syrupo.

2.—R. Hydrarg. Chlor., gr. ij.
Sacch. Purific., gr. v.
Misce. Detur secundâ quâque horâ.

Should the convulsions not subside under this treatment, and there be reason to fear that serous infiltration has taken place, a large blister should be applied to the head, and strong mercurial ointment, spread on lint, laid along the course of the lymphatic vessels upon the inner surface of both upper arms, but under such circumstances there can hardly be any expectation of recovery.

Strumous Ophthalmia.

This disease is of frequent occurrence in crowded seaport towns, and affects children from about two to ten years of age. I have found it more common in females than in males. It cannot easily be mistaken, and is at once recognised by extreme intolerance of light, by the head being bent down to avoid it, by a copious discharge of tears on separating the tarsi, and by the difficulty of getting a sight of the cornea, which is kept concealed under the upper eyelid. There will also be a lesion of the cornea, and a red zone around it, occasioned by an inflamed condition of the sclerotic membrane.

This disease is to be treated by local bleeding, in the way of leeches or cupping, by the caustic lotion, (1), by the ointment, (2), and by the calomel doses, (3), which will, in the majority of cases, speedily subdue it.

1.—R. Argent. Nitratis, gr. iij.
Aquæ Flor. Sambuci, oz. j.
Misce, et destilletur pauxillum intra palpebras bis die.

2.—R. Ung. Hyd. Nit. Oxidi, dr. j.

3.—R. Hydrarg. Chlor., gr. vj.
Sacch. Purificat., scr. ij.
Misce et divide in chartulas sex, quarum capiat unam omni meredie et nocte.

Very much will depend, as to the local treatment, upon the lotion being effectually thrown over the cornea, and this may be done either by a glass syringe, or by means of a silver teaspoon, to conduct the lotion between the tarsi. If these means should not succeed, removal to a different atmosphere will soon effect a cure.

It is remarkable how long this disease will sometimes remain without destroying the vision. The two following cases will go to prove this fact.

A child, of 4 years old, and residing in a country town, had been suffering from strumous ophthalmia in both eyes for more than a year. When she was brought for my advice, the head hung down upon the chest, under a thick green veil, to avoid the light. She had been under the care of a respectable surgeon, who, I have no doubt, ordered the most judicious means for the cure of the disease, but, as they were not *strictly* enforced, so neither were they carefully carried out, and the result was no improvement. Having told the parent in charge of the child, that unless the lotion was effectually applied to the lesion of the cornea, and the medicine regularly given, the sight would in all probability be lost, implicit obedience was promised. On the 21st of June, 1850, about a month afterwards, the child was brought to me again, when I had the satisfaction to see her with two bright black eyes, free from any trace of inflammation, and the vision completely restored.

J. N., a little girl, aged 6 years, had been suffering severely with strumous ophthalmia for nine months. The eyes were intolerant of the least degree of light, were constantly closed, and guarded by a green shade. The child had been under medical advice for a considerable time, but it appeared, as in the former case, that the means recommended had not been carefully carried out. I immediately placed her under the treatment above laid down, and charged the parent, if she regarded the vision of her child, to see that the instructions were strictly obeyed. She did so, and the result was, that in a few days there was much less intolerance of light, and that in three weeks the disease was cured.

Cachexia Scorbutica in Children.

Amongst the lower grades of society children are sometimes affected with scorbutic, spongy, and bleeding gums, associated with superficial ulcerations of the membrane of the mouth, fœtid breath, pallid aspect, and very low power, symptoms which have probably arisen from crowded habitations and deficient diet. This wretched state admits of rapid improvement, by the lotion, (1,) the mixture, (2,) and a generous diet.

1.—R. Solutionis Chloridi Calcii,
Mellis Rosæ, sing., oz. ss.
Aquæ Puræ, oz. v.
Misce fiat lotio ter die utenda.

2.—R. Quinæ Disulphatis, gr. vj.

Tinct. Aurantii, Comp.
Syrupi Zingiberis utrq., oz. ss.
Aquæ Destillatæ, oz. ij.
Misce capiat cochlearia parva duo bis quotidie.

The lotion should be carefully applied to the mouth and gums by means of a syringe or camel's-hair brush, unless the child be old enough to use it in the ordinary manner. The bowels are to be regulated by rhubarb or castor oil. The diet is to consist of animal broths and a little wine, and the child taken out into the air as often as the weather permits.

Cachexia Verminosa in Children.

This case is characterised by a pallid, half-starved aspect, with attenuation, picking of the nose, morbid appetite, abdominal enlargement, and lumbrici in the alimentary canal.

The cachectic condition arises, probably, from debility of the digestive functions, thereby admitting of the formation of the entozoa. The lumbricus is more commonly met with in the human body than any other worm, and sometimes a considerable number will exist in the intestinal canal of one individual at the same time. A child of 5 years old, residing in the New Forest, passed seventeen full-sized lumbrici in the course of five days. They are generally voided by the rectum, but occasionally by the œsophagus, and thence through the mouth or nostrils.

Gnawing pain in the region of the stomach, a constant craving for food, irritation of the nose, and occasional moving sensations at the upper part of the intestinal canal, more particularly indicate the presence of this worm.

This case will be successfully treated by the aperient (1), and the chalybeate (2). The former will sweep out the intestinal canal, and improve the secretions; the latter will not fail to strengthen the depraved condition of the system. A generous diet is indispensable.

Cachexia Syphilitica in Infants.

This depraved condition of the system in infants is not uncommon, and must have been communicated by the parent in utero. Soon after birth there is an acrid discharge from the nares, producing obstruction to the nasal breathing and constant snuffling, which occasions an excoriation of the upper lip. There is also frequently a squamous eruption upon the angles of the mouth, and condylomata around the anus. If the progress of the disease be not arrested, it will extend to other structures, and ultimately involve the bones of the palate, nose, and upper jaw. From these results the auditory function is often obliterated, and the tongue being untutored by the ear, the child will become deaf and dumb for life. This disease is curable by medicine, unless struma be associated with it, and

there be set up a strumo-syphilitic diathesis. The mode of treatment would consist of the iodide of potassium and mercurial alteratives, the doses of course to correspond with the age of the child. In infants, the formula 1 and 2, will be sufficient for the system. If there be any eruption at the angles of or about the mouth, it may be smeared, morning and night, with the ointment, 3; and should there be condylomata at the anus, the caustic lotion, 4, may be applied to them twice a day, by means of a camel's-hair brush.

This treatment is to be continued till the disease has disappeared.

Cachexia ex Alvi Fluxu in Infants.

Cachexia in infants is sometimes the result of long-continued diarrhœa, brought on either by a morbid secretion of the mammary function on the part of the mother, or, if it arise after lactation, by careless and improper food. The child, from this constant out-run from the bowels, is often reduced to an *extreme degree* of attenuation, has a senile aspect with large features out of all proportion to the shrunken appearance of the countenance, and looks like a living skeleton. Although an infant in this state may appear, *primâ facie* to be beyond the reach of human skill, the contrary is more commonly the fact; for, by judicious treatment as to medicine and diet, and above all, by the kind attentions of a nurse, the secretions may be corrected, the diarrhœa controlled, and the health restored. The two first may be accomplished by 1 and 2:—

M. Detur cochleare parvum bis terve die.

The food which I have seen attended with the greatest success, is boiled flour and skimmed milk, prepared in the following manner:—Take a sufficient quantity of flour, tie it into a linen cloth, and boil for several hours till it becomes hard; then peel off the outer part and grate the centre into skimmed milk till it becomes the consistence of gruel; add powdered white sugar, and let the child be wholly fed with it until the health is restored.

Cachexia Purulenta in Children.

The species of cachexy here alluded to, is the result of long-continued purulent discharge from external causes. The child is pale, emaciated, and almost exhausted, simply by the quantity of discharge. There is no hectic fever, and the case is curable. The following example will show both disease and treatment. :—

A child of a year old was brought to me a short time ago from the Isle of Wight, with a disease of the os ilii. It was so reduced and attenuated by the constant discharge from several openings, that there did not appear to be any rational hope of recovery; however, I ordered fifteen drops of the Vinum Ferri to be given to it three times a day, with a nutritious diet. In a month I saw the child again, and there was a remarkable improvement, both in the local disease and in its general health; after about the same interval, it was brought to me the third time, when the openings were almost healed, and the child was convalescent. I am happy to perceive that the London College of Physicians has thought fit to restore the Vinum Ferri to its place in their new Pharmacopœia, as I have ever found it in the diseases of children requiring chalybeate medicine, a most convenient and effectual preparation.

Cachexia Eczematosa in Children.

This disease is very common amongst the ill-fed and neglected children of the lower classes. There is a pale and sickly aspect, and on different parts of the scalp the hair is matted together with filthy scabs, of eczematous secretion, from which exudes a thin and irritating discharge. There are also weak ulcerations behind the ears, and about the angles of the mouth, and on the nares, &c.

There is no eruptive disease more easily got rid of than this, provided the treatment be carefully carried out. The whole of the scalp having been closely clipped, and the scabs removed by poultice or fomentation, the eczematous parts are to be smeared by the ointment, 1, twice a day, and well fomented before each application. The alterative dose, 2, is to be given twice a week, and the strength supported by 3. By these means the removal of the disease will be at once accomplished.

[To be continued.]

CASES OF POISONING BY DATURA STRAMONIUM.

By JOHN LE GAY BREWESTON, M.D., Edin.
Doncaster.

Early in the afternoon of the 14th of October I was summoned to see two children of the respective ages of five and three years, who were described by the messenger as having suddenly "gone out of their heads." They had been picked up in the street in this state, and carried into the house of the stranger.

I immediately recognised the symptoms of poisoning by one of the *Solaneæ*. The face was flushed; the eyes were staring and brilliant, and the pupil was fixed and excessively dilated. There was complete loss of vision, imperfect control over voluntary muscular action, and violent delirium, which was alternately mirthful, furious, or dolorous, directed to some imaginary source of pleasure or repugnance, and accompanied with corresponding gesticulations. The tongue was occasionally thrust from the mouth, and the throat, which appeared to be the only sensible seat of discomfort, was grasped and torn by the hands, as if the patients imagined it to be oppressed by some foreign body. Their attention could not be aroused to anything which was said, and they resisted all attempts at interference with piteous cries or violent struggling.

I suspected the poison of belladonna, and caused search to be made in the neighbourhood for the berries of that plant, administering emetic doses of sulphate of zinc in the mean time. The patients exhibited apparent reluctance to swallow, keeping the jaws rigidly closed, and resisting the administration of the remedy with their hands, though they were not sufficiently conscious properly to direct such efforts. The stomach was slow to act, but after considerable perseverance vomiting was induced. Numerous seeds of *datura* were detected in the ejecta; indeed a much greater quantity than has been known to cause death.*

It seemed, from the search which had been made, that the poisonous herb had been thrown out from a neighbouring garden, and several emptied and divided thorn-apples wore discovered. A third child confessed to having eaten a smaller quantity of the seeds, and she was slightly though not alarmingly affected. The poison having been retained four or five hours when vomiting took place, a sharp aperient dose was administered, which, after some hours' delay, acted moderately. Cold was from the first assiduously applied to the head.

At five o'clock, P.M,, four hours from my being first called in, though the symptoms were somewhat abated, vision and consciousness to external things were not restored, and the delirium returned at intervals with nearly all its previous violence. The parents of the children, who were now present, were not noticed by them, save occasionally to be embraced or attacked for some imaginary benefit or injury. I subjected the patients to a shower-bath, and applied a blister to the back of the neck.

At nine vision was partially restored in the elder child, and the *hallucinations* were in a great measure supplanted by *illusions*, which indicated some return of consciousness.

At eleven the delirium had become of a muttering type; the patients were drowsy, and displayed a comatose tendency. In the elder child *the pupil, though contracted in the dark, gradually dilated to the stimulus of light.* Sinapisms were now applied to the feet, calves, &c. Alternate doses of strong tea and ammonia were given; the face was occasionally sprinkled with water, and other means were used to prevent sleep.

At five o'clock the ensuing morning, the victims were allowed to sleep, and both awoke before noon, perfectly conscious and well.

On the morning of the third day, the body of the younger child became covered with a small papular eruption, which continued for several days, accompanied with fever.

The effects of the poison were *purely nervous.* The *cerebrum* was first affected; hence arose perverted vision, illusive delirium, and, as consciousness diminished, pure hallucinations. The derangement next attacked the *cerebellum*, as was shewn in the loss of control over voluntary muscular action.

Finally, the *medulla spinalis* was implicated, as was evinced by the spasmodic motions of the extremities, &c. In each organ, the first effect seemed to be *stimulation.* This was followed by *pervertion*, and lastly, by *depression*, and threatened *extinction* of the function.

It is then incorrect, with such evidence as the above recorded symptoms present, to class *datura* among the *narcotico-irritant* poisons. This term has been vaguely applied by toxicologists to several poisons which are in no proper sense of the term irritants; and which only differ from the the *narcotics proper*, either in affecting more peculiarly the spinal cord, or in the stimulating effects—the first result of all narcotics—being more marked or of longer continuance than the narcotism which follows. Death may even occur from over stimulation, before the depression sets in. I have, for instance, poisoned animals with Indian hemp, some of which have died in a state approaching to *tetanus*, while others have survived this stage to perish by *coma*, or, at least, by *nervous depression.* It is probable that a poisonous dose of *strychnia*, if it did not first kill by over-excitation of the spinal cord, would eventually do so, like *aconite*, by depression of that organ.

* See case recorded by Dr. Thompson.

ON THE

ABSENCE OF PHOSPHATES IN THE URINE OF THE HERBIVORA.

By C. R. BREE, Esq., Stowmarket.

The recent analyses of Bousinghault, Von Bibra, Ausbücher, &c., have decided that there are no phosphates in the urine of the horse or ox. This remark-

able fact is alluded to by Liebig, in his "Letters on Chemistry," p. 403-4; and he attempts to account for it by stating that the intestines perform, in those animals, the functions of the kidneys, the phosphates being cast off among the solid fæces. Liebig further draws an analogy between this supposed function of the intestines of the herbivora and the diseased action in diarrhœa in the human subject.

I wish to call the attention of chemists and physiologists to these statements, as it is evident they have a most important bearing upon the whole subject of excretion, in its most extended sense, as elucidated by the modern investigations of chemistry and the microscope.

If the analyses of the celebrated men above mentioned are correct, we have presented to us the fact, that the phosphoric acid of the brain, bones, and protein compounds of the herbivora, which are thrown off by the constant waste going on in the system of these animals, is excreted, not by the depurating action of the kidney, but by the intestinal tube; and this not by an abnormal exosmosis, as in diarrhœa, cholera, malæna, &c., but by a clear act of organic selection, which I believe I may state has no parallel in physiological science. *Qui facit per alium, facit per se.* If the intestines depurate the blood in the ruminantia and the equidæ, why not in the pachydermata (as the pig), in the rodentia (as the hare), or even in the omnivora (as man)? I need not point out to the comparative anatomist that the equidæ are placed between the pachyderms and rodents; and yet there are phosphates found abundantly in the urine of both the pig and the hare. We must not look for an explanation of this anomaly, then, in anatomical relation, for the ruminant is much further removed from the equid than the latter is from the pachyderm or the rodent; in fact, equidæ are placed by Cuvier among the pachydermata. Neither can we find an explanation in the nature of the food; for the question is not how the phosphoric acid gets into the system, (and get in we well know it must, and that in the ordinary process of chylification and absorption,) but the difficulty is, how it is removed from the blood so as to get into the fæces, and not appear at all in the urine. If it is simply by exosmosis, then the process may take place as well in the human subject; so that when we find no phosphates in the urine, abundance may have passed off *from the blood* by the intestines.

Thus all our recent notions of the chemical pathology of the urine would be upset. If, again, the intestinal tube in the herbivora acts as an organ of excretion *to the blood*, in the same sense as the kidney does, then must our notions of the physiology of secretion undergo great modification.

In the hope that some of our physiologists may throw light upoh this interesting point I submit it to the notice of our Association.

STRONGYLUS SUIS IN THE BRONCHIAL TUBES OF A PIG.

By C. R. BREE, Esq, Stowmarket.

A few weeks ago, when examining the lungs of a recently-killed pig, I found the bronchial tubes infested with vast numbers of entozoa, which Professor Owen, to whom I sent the specimen, informs me are the rare *strongylus suis* of Rudolphi (Synopsis Entozonum, p. 36, No. xxxviii.)

This parasite was about three quarters of an inch to one inch in length, and was attached to the angles of division of the bronchia through the whole lung. Having placed one of them in a watch-glass, I was fortunate enough to witness, through the microscope, the exclusion of vast numbers of *ova* from the female. I could not satisfactorily make out whether I had both male and female specimens coiled up and attached to each other, or only one female. At a few lines distant, however, from the extremity of one, there was a process formed in the shape of an ∠, from which I observed the slow and gradual emission of a diaphonous tube, filled with minute circular flattened discs, of a dark colour with a pellucid centre. As this tube emerged from the vulva, I observed that it increased in thickness, and contained more ova in a line. These ova appeared to have a slight motion. Several of these tubes, measuring about half the length of the parent parasite were emitted.

I made these observations about eleven A.M. When I again placed the glass under the microscope, in the evening at six o'clock, I was astonished to find a vast mass of young fry, struggling and wriggling about with great activity. Some had escaped from the hyaline tubes, but the greater number were struggling to get out. I could form no idea of the numbers—they were countless. They continued active until I went to bed; and failing to leave sufficient water in the watch-glass, they were all dried up in the morning.

Stowmarket, 1851.

CASE OF

POISONING BY THE BI-CHROMATE OF POTASH.

By JOHN WICKENS WEST, Esq., Poole.

Very lately I was requested to visit a professional friend residing in Poole, who had inadvertently tasted a solution of the bi-chromate of potash. The quantity he swallowed did not exceed a teaspoonful, if it were as much. He discovered his mistake shortly afterwards, but did not experience any ill effects until about half an hour, when he felt sick, his countenance became pale, and he became quite prostrate. He being at a midwifery case at the time, was compelled to leave, and requested me to attend on his behalf. Before the

delivery of the woman I was sent for to him. I found him in bed; he had been profusely sick, and had thrown up a serous-looking fluid, resembling the evacuations of rice fluid in cholera; diarrhœa constant, and the evacuations passing away involuntary; the bed was perfectly swamped; cramp in his legs, thighs, and in the region of the heart; great prostration; pulse small and exceedingly depressed, so much so, that I felt a little alarmed at his state. On his arrival at home, and previously to my seeing him, he had taken some warm tea, which increased the vomiting. As the diarrhœa was profuse, I admininistered the following draught:—R. Tinct. Catechu., dr. ij.; Tinct. Opii, m. xl.; Tinct. Cinnam. Co., dr. j.; Aquæ, oz. iss. Sit haust.

I also gave him strong brandy and water at short intervals. In about an hour the sickness had subsided, and the diarrhœa was not so urgent; it had produced great debility. Flatus was then oppressing his stomach exceedingly, and I gave him the citrate of potash, which relieved him much; he had also a warm bath. Before the close of the day, all his symptoms were relieved. He took some arrowroot, and afterwards procured a little sleep. When calling on him in the morning, I found he had passed a good night, and was sufficiently recovered to resume his professional duties. I put this case on record, as poisoning by crome or its preparations is of rare occurrence. Professor Taylor, in his excellent work on Medical Jurisprudence, speaks of only one case having been related; I have not been able to discover any instance of it myself.

It will appear from the foregoing case, that the bichromate of potash produces symptoms exactly similar to cholera: such as vomiting, purging, cramp, and great prostration of strength; and as soon as the poison is evacuated from the stomach, must be treated in the same way.

WHAT OUR ASSOCIATION MIGHT DO.

By C. RADCLYFFE HALL, M.D.,
Torquay.

For the "Provincial Medical and Surgical Journal."

No. IV.

The frequency of difference of opinion amongst medical men is proverbial, and is deemed by every non-professional person to be a sufficient excuse for deciding for himself any point on which "doctors disagree." Our differences of opinion, referring as they do principally to general and superficial questions, are placed more prominently before the public, and are more open to the apprehension and judgment of the non-medical world, than the innumerable truths of medicine on which we all agree.

On what do these differences of opinion depend; and, being evil in their consequences, how far are they unavoidable?

Individual differences of opinion on matters which require minute investigation depend on the difference in perceptive power, attentiveness and clearness of thought, of different men, and must always exist. In the possession of these qualifications mainly consists the superiority of one medical man over another. This, however, at least in theory, is as plain to the public as to ourselves; and from this the profession does not suffer in general estimation. The differences of opinion from which it does suffer concern subjects which ought to be matters of fact, but which are at present still matters of opinion. We cease to differ upon any point the moment that fact is substituted for opinion. No medical man gives it as his opinion that small-pox is not contagious; because the question has been decided by facts, and is no longer a matter of opinion. But one man considers cholera to be non-contagious, and is supported in such a view by the combined intellect, &c., of Government; whilst another, unable to gainsay his own experience, asserts that cholera is contagious. So soon as a sufficient accumulation of facts has settled the question there will be as little difference of opinion upon this as there is upon the contagiousness of small-pox. All we need in order to render our views unanimous upon any point is simply to learn the exact truth regarding it. In proportion to the extent and exactness of our knowledge of facts will be the unanimity of our sentiments. Upon the same fact two persons can differ in their opinion only when the fact in all its bearings—*i. e.*, the whole of the fact, is not known to both. The same fact being perfectly known to the one, and but partially known to the other, is virtually two different facts. Each person reasons from his own premise correctly; but only one of the two has a true premise, and consequently he alone can obtain the true inference. Or, again, from imperfect knowledge of the fact, any number of false premises may be taken, and any number of correct inferences, but erroneous conclusions, deduced from them. We are brought back to the same point—namely, that the only mode of obviating differences of opinion is to ascertain the facts.

Every question demanding for its solution minute investigation of particular facts must ever remain the work of an individual or of a few acting in unison. But there are many questions of a general character requiring multitude rather than minuteness of observations, which the experience of one or of a few individuals can never be sufficient to decide. It is precisely on these general questions that we differ most, and most conspicuously to the world. Every man prefers a resting-place for his mind, and rather than possess no opinion he makes one from his own limited experience. The grounds being inadequate in each instance, we may find as many opinions as thinkers. Nor is this all. In the ignorance of the actual truth we do not content ourselves with merely drawing inferences from our own experience, but we arrange for Nature what she ought to do, and retain tenaciously just those observations which support our programme.

Has it ever once happened in the history of science that the fact when clearly ascertained proved to be

precisely—neither more nor less—what had been *à priori* conjectured?

In the field proper for individual labour, as instanced in the first of these papers, scientific workmen need no spur. Were all the diligent investigation as well directed as it is energetically pursued, we should advance still more rapidly than we do; but in reality, the advance in our knowledge of the *minutiæ* of medical science is extremely great, and is shown as remarkably in the unlearning of fallacies as in the acquisition of new truths. On the other hand, the increase in our knowledge upon such general medical questions as the public can judge of, and by which alone they are able to estimate the scientific character of medicine and of its followers, does not keep pace with the progress in our knowledge of scientific *minutiæ*, of which the public are almost entirely ignorant.

The rectification of this deficiency must be the work of an association, or of several associations. If left until individuals shall have accumulated the required facts in number sufficient to remove contrariety of opinion, we may judge of the future by the past. Why should not Our Association do some of this work? Leaving generalities, what work is meant, and how is it to be done?

Questions of Special Pathology, of Anatomy, Physiology, and Chemistry, are best left to their especial votaries. Our Association, as a body, can do nothing with them. Medical Politics and Ethics we leave to those who like them. We suppose they may be suitable subjects for the Association. Cases, unless narrated with the fulness of detail of those published by Dr. Taylor on pericarditis, or by Dr. Walshe, on various clinical subjects, are perhaps less useful—they are certainly less read—than their reporters expect. Being rarely more than could be paralleled every day in a large practice, or a moderate-sized hospital, they seldom repay perusal. Reports of Pathological Societies, conveying a concise statement of observed facts, are more useful; and reports of Branch meetings are, at least, more entertaining. But the field of medical science which is most proper for the Association to cultivate is that which comprises General Hygiene, Climatology, Etiology, and the Mutual Relationship of Diseases; all cognate subjects;—all subjects upon which, more than any other, we differ in our sentiments;—and all subjects upon which non-professional people can form an opinion for themselves—can seek our opinions, and can judge them.

These subjects agree in another and very relevant particular; and it is this:—They are such as cannot be duly examined either in hospital practice or in town consultation practice. Hearsay evidence from patients often but little capable of observing correctly is all that is to be obtained there. The provincial practitioner, having the same patients and families—the same localities and customs, classes and occupations, under his own observation year after year, is personally acquainted with the facts, must notice them, and has no temptation or motive for involuntarily colouring them. There is the same differenee in the two kinds of evidence that exists in diagnosis between an objective sign and a subjective symptom; almost the same that exists for purposes of induction between a proved fact and a supposed one.

Hygiène includes the consideration of all circumstances, the administration of medicinal agents excepted, which promote, maintain, injure, or destroy health. The subjects of physical climate and of the general causation of disease are branches of hygiène. The regimenal treatment of disease constitutes special hygiène. Concerning so extensive a department of knowlege, we cannot in the present day subscribe to the opinion of Rousseau, that "l'hygiène est moins une science qu'une vertu," unless in the sense that we all of us know more of hygiènic truth than we choose to put in practice.

It is no part of my present object to enumerate the questions on which information is most needed, and on which it could be obtained with the greatest authenticity and readiness from the members of our Association. My purpose will be fulfilled if I can succeed in directing attention to the kind of subjects which are most suitable, most important, and most easy of investigation. We muster about fifteen hundred members. There is scarcely a general question upon which each member has not observed for himself, one fact which struck him as noticeable at the time. How few are the unsettled questions which would not be set at rest by 1500 accurately observed facts! How small would be the differences of opinion on points upon which 1500 facts had been brought to bear! We cannot, it is true, emulate the Medical Society of Observation of Paris, or the younger one of London, in the minuteness of their observations. But the subjects assumed as most fitting require no such minuteness. In respect to them, what prevents our becoming a Great Society of Observation?

Take, for example, the important question of the effects of total abstinence. We need no additional information as to the universally injurious effects of the intemperance of excess. We do, perhaps, require additional precision in our knowledge of the exact forms of disease in which such effects are made manifest. We need no additional information as to the occasionally good effects of total abstinence, the universally good effects of temperance, or the frequently good effects of alcoholic stimulants given as hygiènic remedies in disease. On these points we are of one opinion. But, apart from actual disease, is not such an injury *sometimes* inflicted by the adoption of total abstinence succeeding to the habitual moderate use of stimulants, as to convince the medical observer that there is intemperance on the side of deficiency, as well as on the side of excess? Noting that one man has habitually too much red blood to excite him, another too little; one too much energy, another too little; that perfect health is almost a visionary abstraction, good health being practically the best which the individual can obtain, so long as it suffices for the duties of life, and not that ideal perfection that the physiologist could portray; there is every likelihood *a priori* that total abstinence will be best for one

man, moderate use of stimulants for another. Excessive use, or abuse, for none. Such *a priori* reasoning, added to the testimony of individual experience, guides us at present. It has little force on enthusiasts. It is not convincing to ourselves. Fifteen hundred examples in point would decide the question for ever.

Amongst the most useful essays called into being by our Association, will permanently rank those on Medical Topography, published in the annual "Transactions." It is to be hoped that these will be continued, and on a definite plan, so as to facilitate reference and comparison. This was earnestly suggested by Dr. Sibson, at the Hull Anniversary Meeting, and has been as earnestly advocated in the *Journal* by Dr. Barham, of Truro. Owing to the lamented death of Dr. Mackness, who was appointed to draw up an Essay on the Medical Topogrophy of the southern part of Sussex, which was expected to exemplify the most suitable plan for future adoption, we are yet without a specimen essay. By collating the several admirable essays which we already possess, and culling from their respective excellencies, it would be exceedingly easy to lay down a pattern arrangement for future writers to follow; we should thus escape too much detail on irrelevant topics, and too little on essential points. A small committee might, with propriety, be appointed to consider and prepare such a plan ready for the next annual meeting.

But the great value of such reports depends entirely upon the number and exactness of the facts which they can bring under consideration. Facts relating to climate, especially to the local variations of the same climate, which are so important in respect to disease, cannot be collected in a day. To render our knowledge of the physical climate of any place tolerably complete, we require to know:—as regards the place,—Its geographical position, whether maritime or inland, close to a river, or lake, or canal, or marsh, or low swampy ground. If near a river, whether a tidal one. Its elevation above the level of the sea. Its situation, whether exposed or defended. Its aspect towards the horizon. The proximity of lofty hills or mountains. Its geological character, particularly in reference to the superficial strata; and to the nature of the soil, whether absorbent and retentive of moisture, or absorbent and rapidly drying, or not absorbent but, from amount of fall rapidly drying; whether absorbent or reflective of the light and heat of the sun. The quality of the spring water, its abundance or scarcity. The vegetation, whether abundant or spare, and its general character. As regards the atmosphere:—The direction and ordinary force of the winds; the quantity of rain and number of wet days in the year; the frequency and duration of fog and of snow. The heat, humidity and electricity of the air. The intensity of solar light.

For so much of medical topography, therefore, as relates merely to physical climate, it would be absurd to expect every member of our Association to collect the details regarding his own locality. But this is not required. Most of the particulars referred to are obtainable from other sources. By far the most important points, however, are contingent upon two conditions, namely, the heat and humidity of the air. The electricity of the air should perhaps be added, but this we possess, unfortunately, at present, no ready and available instruments for ascertaining. Ozone paper promised to be useful, but the trial has not fulfilled the promise. For ascertaining the heat and moisture of the atmosphere, the means are simple, easy, comparatively inexpensive, and require very little attention or trouble. The information gained even for a single year would be most valuable. By collating it with the diseases prevalent in the same year, and comparing the reports of different localities, a body of knowledge on the "Epidemic Constitution of the Year" would gradually accumulate, the importance of which after a series of years would be incalculable.

A single observation daily of Mason's hygrometer would give the heat and moisture; an observation of the differential thermometer would give the greatest amount of cold, and of warmth in the previous twenty-four hours. All necessary instructions are contained in Glaisher's Hygrometrical Tables. If only one instrument be used, the wet and dry-bulb thermometer (Mason's hygrometer) is to be preferred; since the mere temperature of most localities is already obtainable, whilst the degree of humidity is not. Either or both of these instruments suspended at a distance of eighteen inches from a north window of a room in which no fire is kept, and observed at one given hour (say nine A.M.,) every day, might be used by at least one member of the Association in every locality, where some institution at which these observations are made already, does not exist. One such observation noted daily would not give the *mean* temperature and moisture, but taken for a sufficient period it would give the *actual* temperature and humidity at the given hour of the day; and this would be quite enough for useful comparison,

If the good to be gained by such observations does not appear adequate to the trouble they require, (although the trouble is really very trifling,) we reply, that before we have obtained the facts we cannot foresee all the advantages to be derived from them.

Literary men have their "Notes and Queries;" and in law periodicals there is a department headed "Moot Points," under which any legal queries of which the solution is not clear and established, are stated, to be answered by any one who has an answer to furnish, in a future number of the journal. In our journal we have the machinery at hand without any additional expense. "Moot Points" in medicine, there are in plenty. To make "Notes" on disputed points is not difficult: and nothing is easier than to propound "Queries." To some extent the Association has already thus been made useful. Dr. Streeten published "Queries on Influenza;" Mr. Hunt, "On the Effects of Arsenic," and on "Cholera;" Mr. Crompton, "On Burns and Scalds;" Dr. Ranking, "On the Effects of Cod-liver Oil;" and Mr. Bower Harrison, "On Necrosis caused by Phosphorus." The information elicited (if any), was valuable, and as a whole, on some points considerable. But in comparison with the information really existing

amongst the fifteen hundred members, it was most inconsiderable; and in no degree did it constitute a fair representation of the intelligence of the Association.

There are many reasons for the disinclination of professional men to give up information just when and as it is asked for. In the first place, there is the impression of submitting to something dictatorial in being questioned at all—a feeling not lessened by the reminiscence of academical questioning. Then there is the doubt of any good result, worthy of the effort, being gained if the replies are furnished. The man whose experience would afford him much to communicate is fearful of lowering his position by doing anything that the majority of others could do. He would rather be silent than common-place. One has facts of value on the required subject, but he sees no reason why he should place them at the disposal of another; he intends to use them himself at that convenient season which so seldom comes. A second has certainly a few facts which are pertinent, but he suspects that A and B may have more, and he does not choose to appear to have had less experience than they. A third considers that the plan is not bad, and that replies are desirable, and he hopes that *others* will attend to them. A fourth inclines to give replies, but postpones. A fifth prefers "something more practical;" which, being interpreted, generally signifies, something that requires neither trouble nor thought.

To lessen these objections we should propose such queries only as are of manifest importance, cannot be duly answered by the private exertions of any one or two individuals, make no considerable demand upon the reflection or time of the profession to answer, and to which the answers are comparatively of no value, unless when obtained in large numbers.

In furnishing the results of observation the only essential condition to be borne in mind is, that the writer shall state no opinion which is not founded upon his own observation, and shall state nothing as fact which he has not observed for himself. The mode of reply, whether anonymous to the public, or publicly authenticated by name, is purely a matter of taste and convenience. The greatest man would not be demeaned by giving a few facts anonymously; the smallest need not feel ashamed of stating actual observations publicly.

What are eligible "Moot Points" for the consideration of the profession, as a body, is a question best left to those conversant with the given subjects. A "moot point," to one who has not especially investigated the particular branch of medical inquiry, is often a point quite ascertained to him who has. But there is one class of queries particularly suitable, since they can scarcely be otherwise solved, namely,—those which relate to the influence exercised by one disease, or one set of diseases, over another, either in causing a predisposition, in lessening liability, in conferring an absolute immunity, or even in effecting a cure. This Relative Pathology, if we may so term it, promises richly to reward investigation, by indicating to us what are the means adopted by nature for promoting, opposing, preventing, or removing special disease.

How largely might Our Association add to the established truths of medicine were each of its fifteen hundred members to furnish one observed fact on every important question submitted to his consideration.

In these papers, now brought to a conclusion, it has been far from the intention of the writer to dictate to his peers and his superiors in the profession, what they ought to think or what they ought to do. His desire has been to give expression to his own sentiments on matters medical in their very anomalous position at the present time, in the hope that if he could strike a responsive chord in the minds of others, he might haply in some small degree promote that unanimity of sentiment which is the necessary precursor of unity of action. He is convinced that the united endeavours of fifteen hundred educated gentlemen, scattered through the length and breadth of the land, would go very far in that most difficult of all missions—making TRUTH the FASHION.

Provincial Medical & Surgical Journal.

WEDNESDAY, DECEMBER 24, 1851.

The provisions of the recently promulgated Draft of a Charter for the Royal College of Surgeons are so nearly in accordance with the views which we have invariably advocated, in common with the majority of our Associates, that we do not hesitate to receive it as a liberal concession to the just demands of the profession. The chief points upon which there is likely to be a difference of opinion among provincial surgeons are:—1st. The election of Members to the Fellowship without examination. 2ndly. The fee to be paid upon such admission. 3rdly. The non-admission of proxies in the election of Fellows to the Council.

The clauses which we think will be unhesitatingly received and approved of are, the following, viz.,—1st, the admission, *ad eunden*, without examination, of Fellows, Members, or Licentiates of the Colleges of Surgeons in Edinburgh and Dublin, and of the Faculty of Glasgow; 2nd, the retirement of members of the Board of Examiners at the expiration of the third year of office; 3rd, the constitution of a Board of Examiners in Midwifery; and, 4th, the distinction now first made in the qualification for the Council between dispensing drugs for the convenience of the medical man, and keeping an open shop for their sale as a matter of profit. In all these latter points we most cordially agree with the framers of the proposed new Charter; but we must strongly contend for the power to vote by proxy in the election of

Councillors, or otherwise the whole of the provincial Fellows living more than thirty or forty miles from London will be deprived of all participation in the elections. It is absurd to suppose that they can be constantly running up to London for that purpose, nor can we conceive any possible objection to the vote by printed lists or by common proxy papers, either of which plans would admit of a scrutiny in case of fraud or error. We are, therefore, decidedly of opinion that the point should be insisted on as a *sine quâ non* in the proposed Charter; nor do we think it likely to be refused if urged upon Sir G. GREY in a proper manner. With regard to the admission to the Fellowship of a limited number in each year of those who would not otherwise enjoy that privilege, not being members prior to 1843, we can see no objection to the proposed power, but we think the number is a ridiculously small one; surely ten or twenty might be the limit, especially as the Council are not to be compelled to exercise the privilege.

We have so often discussed the question of the admission to the Fellowship of members of fifteen years' standing, who obtained their diplomas prior to 1843, that we think it unnecessary again to allude to the subject; it is one which can only be received as a compromise; but in that form it has certainly the support of the majority of the profession, and may, therefore, be considered as a decided concession on the part of the authorities.

With the above exception, therefore, we cannot do otherwise than congratulate our fellow members upon this, as the first instalment of a reform which we trust will speedily be carried out to the fullest extent which is consistent with a due regard to the interests of the whole profession.

Foreign Department.

Extirpation of an enormous Tumour in the region of the Parotid Gland.

A case of the successful removal of a parotid tumour, as large as a child's head, is reported by M. Michaux (*Encyclographie Médicale*). The patient was a young man, aged 25, born of healthy parents. The tumour first commenced at the age of twelve years, as a small moveable knot, under and behind the angle of the jaw, from which it gradually increased to its present enormous dimensions. At the time of removal it occupied the whole side of the neck, extending from behind the ear to the thyroid cartilage, and overlapping the clavicle below, The surface was nodulated. In order to diagnose its nature, a puncture was made with a small trocar, and a portion examined with the microscope; the result demonstrated that it was not malignant and an operation was consented to.

Assisted by his colleagues MM. Craninx and Von Kempen, M. Michaux operated in the following manner:—He first made an elliptical incision for the purpose of removing any unnecessary portion of integument. Two vertical incisions were then made, and formed four flaps, which were dissected extensively backwards, and with very little trouble the mass was isolated and removed; ligatures being required for about a dozen arteries. The recovery was uninterrupted.

In reference to operations for the extirpation of tumours in the parotid region, M. Michaux advances the following general propositions:—

1. We must ascertain whether these tumours are connected or not with the parotid gland,

2. We must satisfy ourselves as to its nature by means of exploratory punctures and the microscope.

3. We must also as far as possible ascertain its limits, especially in depth.

4. If in operating, we find the carotid is likely to be wounded, the vessel must be tied above and below the tumour.

5. The deep attachments of these tumours should be separated by the fingers, and no incision should be made until we are sure no important vessel lies beneath the scalpel.

On Paracentesis Thoracis.

Among many interesting discussions which have recently taken place at the Medical Society of Hospitals in Paris, that on the indications for, and performance of, paracentesis thoracis is well worthy of commemoration. The debate was opened by M. Trousseau, who has long insisted on the advantage of early resort to this operation, not only in chronic pleurisy, but also in the acute form of the disease, when the effusion is considerable. He has in his own practice performed the operation twenty-one times, in eleven of which it was for acute pleurisy, and successful in all. In eight other cases the effusion was of old standing and purulent; five of these died, and two were completely and one imperfectly cured. The debate turned chiefly on the propriety of paracentesis in acute pleurisy, and many speakers were found on each side of the question. The general result was that with the precautions recommended by M. Trosseau, the operation is both easy and safe.

As a *pendant* to this discussion, M. Pidoux produced a paper on the indication of paracentesis thoracis, in which he endeavours, to prove that the operation is only suited to what he calls inflammatory hydrothorax, and not to pleurisy properly so called. His remarks may, however, be summed up in the annexed conclusions.

1. Paracentesis thoracis is specially applicable to acute hydrothorax or latent pleurisy, and the comparative pathology of this affection and that of acute inflammatory pleurisy, bears out the result of observations. 2. When practised with the precautions adopted by M. Trousseau it is generally free from danger. 3. When the effusion has reached such an extent that the whole side affected is dull on percussion, and destitute of respiratory murmur, the operation is called for, because little is to be hoped from medicine, and the patient, if unrelieved, may die suddenly, and moreover, sponta-

neous recovery is generally at the expense of great deformity of the thorax and spinal column.

Treatment of Retroversion of the Uterus.—By M. Amussat.

M. Amussat (*Bulletin de Therapeutique*) has reported additional cases in illustration of his new method of curing retroversion by causing adhesion between the posterior wall of the cervix and the vagina. This is done by means of potassa c. calce. He maintains the great superiority of this plan over the stem pessary of Dr. Simpson, and likewise that the agglutination thus induced does not interfere with a subsequent pregnancy.

Correspondence.

THE MEDICAL STAFF OF THE SHEFFIELD GENERAL INFIRMARY.

Correspondence between Dr. Branson and Sir Charles Hastings.

To the Editors of the Provincial Medical and Surgical Journal.

Gentlemen,—The undersigned members of the Staff of the Sheffield General Infirmary, being also members of the Association, request you to publish the accompanying correspondence in the next number of the *Journal*.

We are, Gentlemen,

Your obedient Servants,

FERGUSON BRANSON, M.D.,
President of the Yorkshire Branch of the Association.

M. MARTIN DE BARTOLOME, M D.

HENRY JACKSON, F.R.C.S.

Sheffield, December 18, 1851.

Sheffield, December 10th, 1851.

My Dear Sir Charles,—As I am not personally acquainted with the Editors of the *Provincial Medical and Surgical Journal*, I venture to write to you, as President of the Council, in reference to a leading article which appeared in this morning's *Journal*. In that article an attack is made on the ordinary medical officers of the Sheffield General Infirmary for allowing themselves to remain connected with an establishment, the Governors of which, nine years ago, appointed Dr. G. C. Holland Honorary-Physician for life. The Editors state "that they have not the pleasure of knowing who the ordinary medical staff of the Infirmary may be." A reference, however, to the printed list of our Association would have informed them that three of the staff are members of the Association, and one of them has the honour to be President of the Yorkshire Branch of the Association for the current year. Now, I ask, would it not have been more in accordance with the gentlemanly tone which the *Journal* professes to assume if the Editors had first made inquiry into the circumstances of the case from any one of those Associates connected with the Sheffield Infirmary, before hazarding a direct attack on a body of gentlemen as free from the slightest taint of homœopathy as the Editors themselves. They would then have learnt that Dr. G. C. Holland, after serving the charity for a long period, was nine years ago, in recognition of *past* services, appointed Honorary-Physician *for life*,—a title which, if his services had been of a little longer duration, he might have claimed *as a right* by the rules of the Infirmary. No duties whatever are attached to the office of Honorary-Physician. It is true the medical staff have the power of officially summoning the Honorary-Physicians and Surgeons to a consultation; but I am not aware that such a summons has ever been issued since the office was established, certainly not during the nine years that I have been on the staff of the Infirmary. It will be time enough to blame the staff when they summon Dr. Holland to a consultation. I do, however, blame the Editors for inserting an attack, with all the dignity of a leading article, without first seeking information from those able and willing to give it. Had the information been unsatisfactory it would then have been time to use the lash; though I much question whether our *Journal* can be benefitted by attacks on persons rather than principles. An apology is, I think, due from the Editors to the medical staff of the Sheffield General Infirmary for this unwarrantable attack; and I can assure the Editors that if such attacks are repeated the medical staff will be compelled to entertain the question of resignation—not of their offices in the Infirmary—but of their membership of the Association.

Believe me, my dear Sir Charles,

Very faithfully yours,

FERGUSON BRANSON.

Sir Charles Hastings, Worcester.

Extract from the Rules of the Sheffield General Infirmary.

39.—That such physicians and surgeons of the Infirmary as shall have remained in office twenty years or upwards, on their resignation, shall be, *of right*, Honorary-Physicians and Surgeons of this Charity. Others, on retiring, may be appointed Honorary-Physicians and Surgeons at any General or Special General Board, if the Governors think fit to acknowledge their services in that manner.

40.—That the province of Honorary-Physicians and Surgeons be exclusively confined to consultations of the Faculty, *to which they may be called in*, but that they do not interfere with the practice of the Infirmary in any other respect.

Worcester, December 15th, 1851.

Dear Dr. Branson,—I think it is to be regretted that the Editors of the *Journal* should not have communicated with you or some one of the medical officers of the Sheffield Infirmary before the article, concerning which you have addressed me, was inserted in the *Provincial Medical and Surgical Journal*. I confess that when I read the article in question I was afraid it would give rise to displeasure. If you wish it I will request the Editors to publish either your letter to me or any other you may send, and append to it such remarks as circumstances require. Peace and harmony among the legitimate members of our noble profession being one of the great objects for which we associate, I trust that the pages of our *Journal* may never be the

means of wounding the feelings of any of our associates. It will give me great satisfaction to do all that I can to convince the medical officers of the Sheffield Infirmary that I consider them blameless in the matter in question.

Believe me, yours most truly,

CHARLES HASTINGS.

To Ferguson Branson, M.D., Sheffield.

[The above correspondence was sent us too late to permit any explanation in the present number.—ED. J.]

THE ASSOCIATION MEETING FOR 1852.

To the Editors of the Provincial Medical and Surgical Journal.

SIRS,—I beg to express to you my deep regret, and no little surprise, at seeing you have announced, in the last number of the *Journal*, that the Central Council have been led to alter the place of holding the Anniversary Meeting in 1852 from Manchester to Oxford; and though the circumstances which you state, as having led to the change, may have been worthy of consideration, it is to be feared, from their imperfect exposition, that they will scarcely be held valid enough by the majority of our members to authorise such a change, in the face of the unanimous resolution of the meeting at Brighton, and a requisition from the Local Council that the meeting for 1852 should be at Manchester, and that Mr. Wilson, surgeon, should be president for the year. That the late Dr. Kidd, in the generous devotion of his mind for the benefit and progress of the Association, would have desired to see once more in his lifetime our members gathered together under his auspices in the classic stalls of Oxford, can well be believed, but that he would wish or take any steps, *proprio motu*, to disturb the solemn resolution passed at Brighton, there seems to be much difficulty in understanding without further explanation how this should have been the case.

Such an alteration from the unanimous and recorded resolution passed at an anniversary meeting is unprecedented in the history of our Association, and carries with it some want of deference to the great body of members who reside in Manchester and its neighbourhood, a great many of whom were, it is fully learned, looking forward with much pleasure and satisfaction to the occasion of the anniversary being held in 1852 on the banks of the Irwell, and the meeting to be presided over by their highly-respected colleague Mr. Wilson. Indulging in the flattering view of meeting, in these distracted days of our profession, their brethren next year in the great industrial metropolis of the north, they cannot but feel disappointed that the sedgy Isis has carried off the golden prize for the year, and postponed, *sine die*, the happiness which they had in such proximate view.

It is only fair to suppose that the Central Council have more valid reasons for making such an important change than those which you have been pleased to enunciate, for it is difficult to comprehend how the Local Council and the President-Elect could have receded from their own requisition and acceptance of office, granted and confirmed as they were, by the unanimous approval and resolutions of the very large meeting of members at Brighton. This they could not have well done, without at least having endeavoured to ascertain in some manner the sentiments of the members residing in their quarter of the country. Considering, then, the respectable standing of the members of the Local Council and of the President-Elect, we are induced to think that they must have relinquished their high privilege and right under some constraint or difficulty, which a refuge to Oxford could alone appease or evade. As for the ordinary members in this quarter, they may well say, "what was promised to the ear has been broken to the hope;" and this much may be said for them, that if they had been cognizant, in time, of any change being contemplated—of being deprived the pleasure of seeing the meeting held at Manchester next year—the great majority of them would have subscribed a requisition to forbid the divorce which has taken place. Such untoward and intermittent occurrences are much to be avoided; they create instability in the progress of our Association, and give too floating a character to our proceedings, not only in the opinion of the members themselves, but also in the eyes of the public. This is not the time for the profession to waver in its onward march of science and systematic procedure. The eyes of the public are sharply scrutinizing its ways and means of behaviour; and we look to our Association as the incorporated idea of all that is talented, eminent, and of high bearing, in its widely-located members.

A MEMBER OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

November 29, 1851.

Medical Intelligence.

UNIVERSITY OF CAMBRIDGE.

The lectures in anatomy and chemistry, delivered in the Medical School of this University, are now recognised by the Courts of Examiners of the Royal College of Surgeons, and the Society of Apothecaries, so that students may pass the first winter session, agreeably to the curriculum of those bodies, in Cambridge. The second and third winters must be spent in London or elsewhere. The hospital has long been recognised, and lectures are delivered on medicine, surgery, and other subjects. By this arrangement further inducement is offered to medical students to connect themselves with one of our Universities; for, in addition to the opportunity of acquiring a superior general education, and other advantages of studying in an University, they may proceed to take a degree in medicine, or may be qualifying themselves to practice in the other branches of the profession. Candidates for the Fellowship of the College of Surgeons who have taken the degree of Bachelor of Arts in an English University, are required to have been engaged for *five* years instead of *six* in the acquirement of professional knowledge, and are not required to produce any further certificate in Greek, Latin, &c.

Lectures on all the other sciences collateral to medicine are delivered in the University; and in the last year an Honor Tripos, for the Natural Sciences, has been instituted, corresponding to the mathematical and Classical Triposes, so that the student has an opportunity of distinguishing himself in any or all of these sciences.

MEDICAL BENEVOLENT COLLEGE.

A meeting of the members of the medical profession of the town of Lowestoft and neighbourhood, was held at the Infirmary, on Thursday, the 29th inst., to take into consideration the propriety of forming a local committee in aid of the Medical Benevolent College about to be established in London. W. C. Worthington, Esq., was called to the chair, and the following resolution was carried:—"That in the opinion of this meeting, the establishment of a Medical Benevolent College, including a home for destitute qualified medical men or their widows, and a school for the education of their sons, is most desirable; and that this meeting do resolve to support such a College by donations and annual subscriptions, and to solicit contributions from the profession of this district, and from such benevolent persons as are inclined to promote this charitable object." It was afterwards proposed that the following gentlemen form a committe to carry out the above resolution, and to co-operate with the central committee in London:—Samuel S. Brown, Esq., E. Jeffery, Esq., Dr. Foreman, of Carlton Colville, Alfred Harmer, Esq., of Wrentham, and W. C. Worthington, Esq., Chairman.

ROYAL COLLEGE OF SURGEONS.

The following gentlemen were admitted members on the 5th inst.:—Alexander Fraser Bayne, Reading, Berkshire; Edward Casson, Hull; J. D. F. Cookson, Gloucester; Thomas Gibson, Birmingham; Joseph Lee, Guildford, Surrey; Edward Mercer, Uxbridge; Middlesex; William Thomas Paliologus, Calcutta; John Francis Tierney, Bengal.

The following gentlemen were also admitted on the 12th inst.:—William Augustus Byrne, Great Coram Street; Robert Brudenell Carter, Leytonstone, Essex; James Cornish Crossing, Devonport; Thomas Namby Dean, Manchester; Edward Hier Evans, Cardiff, South Wales; Henry Bowles Franklyn, Army; Richd. Reece, Walton-on-Thames; John Charles Savery, Hastings, Sussex; William Wilking Stabb, Ilfracombe, Devon; John Henry Sylvester, Cheltenham.

SOCIETY OF APOTHECARIES.

Gentlemen admitted on the 11th instant:—Joseph Foster, St. Kitts, West Indies; Henry James Gane, Bath; James Mudge, Bodmin; Ashby Greenough Osborn, Northampton.

OBITUARY.

December 3rd, at his house, 29, New Broad Street, after a long illness, Algernon Frampton, M.D., of St. John's College, Cambridge, Fellow of the Royal College of Physicians, and for many years physician to the London Hospital, in his 49th year.
